Austria's capital has avoided many of the problems—financial crises, social unrest, urban decay—that afflict other European cities. Its people enjoy an enlightened health and welfare system, which originated in the reforms of Empress Maria Theresa and Emperor Joseph II in the 18th century. A city of green parks with ponds, cafés, and playing bands; opulent stores and elegant shopping streets; banks, bookshops, and crowded theatres; and boulevards for leisurely sauntering—Vienna is an invigorating distillation of human energy and imagination.

This article is divided into the following sections:

Physical and human geography

THE LANDSCAPE

Site. Vienna lies in the northeastern corner of Austria, between the foothills of the Alps and the Carpathians, where the Danube (German: Donau), Europe's second longest river, has cut its course through the mountains. The city is situated alongside the river, most of it on the right bank. The Vienna basin was a nodal point of ancient trade and military routes. It linked north and south along the "amber route" that ran southward from the Baltic and linked east and west along the Danube. Strategically, Vienna commands the surrounding regions, which include sections of Austria's border with Slovakia, the Czech Republic, and Hungary.

Climate. Lying east of the Alps, Vienna is protected from their climatic influences by a range of hills, the Vienna Woods (Wiener Wald). The city's weather comes both from the north, the winds bringing cool summers and warm winters, and from the southeast, bringing heat in summer and cold in winter. The result, despite some summer fog and heat and winter snow and ice, is a generally temperate and agreeable climate. Throughout the year the temperature averages above 50° F (10° C). The characteristic *Lüfterl* ("Vienna air"), a light breeze blowing from the northwest and west, provides relief on hot summer evenings. Rainfall is fairly low, averaging 26 inches (66 centimetres) per year, the greater part of it coming in summer downpours.

Layout and architecture. With an area of 160 square miles (415 square kilometres), Vienna reaches across the Danube on one side and climbs into the Vienna Woods on the other. There it includes the 1,585-foot (483-metre) Kahlen Mountain (Kahlenberg) and the 1,778-foot (542-metre) Hermanns Mountain (Hermannskogel), Vienna's highest point. The Vienna Woods slope to the river in four roughly semicircular terraces, with the Innere Stadt occupying the second lowest terrace. The city has a mean altitude of 1,804 feet (550 metres), but different sections vary considerably in height.

The Vienna Woods

A stretch of the Danube was straightened and confined in the 19th century to form the Danube Canal, a flood-control canal, parallel to the main stream, that flows through the city. An island 13 miles long and 750 feet wide was thus created from former floodlands and was equipped as an all-sports park, adding to the city's already generous recreational space. The Lobau, a wooded section along the river, has, like the Vienna Woods, long been a protected greenbelt area. Since the 1970s the open spaces on the far side of the Danube have been exploited for apartment buildings and factories.

Administratively, Vienna is divided into 23 *Bezirke* (dis-

tricts). At the core is district I, the Innere Stadt, which contains most of the city's famous structures. Surrounding the heart of the city is the Ringstrasse, or Ring, a circular road lined with grand buildings, monuments, and parks. Beyond the Ring are the inner suburbs (districts II–IX). The many palaces, churches, embassies, and other buildings in this area are elegant, though generally less imposing than those in district I. Leopoldstadt (district II) was the area allotted in 1622 to the Jews, who lived there until 1938. In this district is the famous 3,200-acre (1,295-hectare) Prater, formerly the hunting and riding preserve of the aristocracy, but since 1766 a public park whose amenities include a stadium, fairgrounds, racetracks, and many restaurants. Beyond another ring road, the Gürtel, lie the outer suburbs (districts X–XX), which are largely residential. Also beyond the Gürtel is the vast Central Cemetery, where many great musical figures and other famous Viennese are buried. Districts XXI and XXII lie on the far side of the Danube; district XXIII is at the southern edge of the city.

Prominently situated in the centre of Vienna is St. Stephen's Cathedral (Stephansdom), one of the chief Gothic buildings of Europe. It incorporates remnants of the original 12th-century Romanesque structure, which was destroyed by fire. Reconstruction began in the early 14th century and continued for a century and a half. The northern tower, never completed, was topped off with a Renaissance dome between 1556 and 1587. The cathedral was again burned and partly destroyed in World War II but has since been restored. The 20-ton bell, made from captured Turkish cannons in 1711, was recast and rehung with much ceremony.

Other Gothic churches include the Church of the Augustinians, the Church of Maria am Gestade, and the Church of the Friars Minor (officially the Snow Madonna Italian National Church), all dating from the 14th century. Vienna's oldest church is St. Ruprecht's. Dating from the 13th century with parts from the 11th century, it is believed to have originally been erected in 740.

The Church of St. Peter, a Baroque structure thought to be standing on the site of a church founded by Charlemagne in 792, was built chiefly by the architect Johann Lucas von Hildebrandt in 1702–33. Other fine examples of Baroque art are the richly frescoed University Church (1627–31) and the Church of the Capuchins (1632), which contains the crypt of the Habsburg imperial family. The Church of the Scots (1155), together with a monastery

The Burgtheater on the Ring and, in the background, the spire of St. Stephen's Cathedral, which dominates the Vienna skyline.

for Scottish and Irish monks, was rebuilt in late Italian Renaissance style in 1638–48. The style of most of the finest secular buildings, such as the Harach and Kinsky palaces and the winter palace of Prince Eugene of Savoy, is Baroque, Vienna's leading architectural style in the 17th and 18th centuries.

The vast complex of the Imperial Palace, the Hofburg (or Burg), lies along the Ringstrasse. It consists of a number of buildings of various periods and styles, enclosing several courtyards, the oldest part dating from the 13th century and the latest from the end of the 19th. The Hofburg abounds in magnificently appointed private and state apartments. It houses the imperial treasury of the Holy Roman and Austrian empires, the Austrian National Library, the Albertina and several other museums, and the Spanish Riding School. The state apartments in one wing of the Hofburg serve as the offices of Austria's president. Close by stands the Privy Court Chancery (1716–21), where the Congress of Vienna met after the Napoleonic Wars.

The Hofburg

The other important buildings along the Ring are mainly mid-19th-century versions of earlier European styles. They include the Stock Exchange (Börse), in Neoclassical-Renaissance style, and the pseudo-Gothic Votive Church, built by Emperor Francis Joseph after he escaped an assassination attempt in 1853. Nearby is the University of Vienna, the oldest university in the German-speaking world, designed in the Italian Renaissance style. The university was founded in 1365, but its original buildings have disappeared.

Another landmark is the City Hall (Rathaus), in neo–Flemish-Gothic with Renaissance touches, and facing it is the Burgtheater, in a mixture of neo–Italian-High Renaissance with Baroque indulgences. The Neoclassical Parliament building lies adjacent to the Palace of Justice, built in 16th-century German Renaissance style. The neo-Renaissance Natural History Museum and the Kunsthistorisches Museum stand in front of an exhibition centre, formerly the royal stables. Across the Ring from the museums is the Hofburg's last extension, the Neue Hofburg, and eastward is the magnificent Vienna State Opera House, built in 1861–69. Purporting to be French early Renaissance, the State Opera is actually a conglomeration of imitative architectural styles, of pinnacles, arcades, colonnades, and heroic statuary, yet it somehow achieves a serene and noble harmony.

On the eastern side of the Innere Stadt lies the City Park, rich in monuments. The Innere Stadt and its immediate neighbourhood are still, unlike the older parts of most European cities, the fashionable quarter, containing the government offices, the principal hotels, embassies and legations, and many other fine buildings. The Schönbrunn Palace, the summer residence of the Habsburgs, with its splendid rooms decorated in Rococo style and its great formal park, lies to the southwest in the suburb of Hietzing.

Another noble structure is the Belvedere, which is actually two Baroque palaces at either end of a terraced garden. It was built by Hildebrandt for the soldier and statesman Prince Eugene of Savoy. The Lower Belvedere (1714–16) was a summer garden palace, and the Upper (1721–24) was designed as a place of entertainment. Both now house museums of Austrian art. The Austrian State Treaty, which ended the four-power occupation of the country, was signed in the Upper Belvedere on May 15, 1955.

The Belvedere

The Church of St. Charles, a vast structure dedicated to St. Charles Borromeo, was erected just outside the city walls in 1716–39. This Baroque edifice is fronted by a severely classical porch of columns in ancient Roman style, and before it stand spirally decorated twin columns carved with scenes from the saint's life. A few streets away from the Church of St. Charles is the Theater an der Wien, built between 1789 and 1801. Mozart conducted the first performance of *The Magic Flute* in 1791 in the theatre's wooden predecessor, and Beethoven's *Fidelio* had its premiere in the newly constructed theatre in 1805. All of the celebrated operetta composers of the 19th century presented works on its stage. In 1962 the municipality bought the dilapidated house, restored it, and now operates it as an orchestra hall.

Two monuments—built by Johann Bernhard Fischer

von Erlach and greatly esteemed by the Viennese—were thanksgiving offerings. One is the 69-foot Trinity Column, or Plague Column, on the fashionable shopping boulevard the Graben, which commemorates the cessation of the plagues that struck the city in 1679 and 1713; the other, in more sober Baroque style, is Joseph's Fountain, a votive column and fountain in the Hoher Market, donated by Emperor Leopold I for the safe return from battle of Joseph I, his firstborn son and heir.

THE PEOPLE

Before and during World War II a number of Vienna's citizens, most notably more than 100,000 Jews, emigrated to the West in order to escape the Nazis. Following the war, Vienna's population decreased when part of Greater Vienna was reintegrated with the province of Lower Austria. There were also moves in population from eastern to western Austria connected with the German annexation of Austria from 1938 to 1945 and the presence of Soviet troops from 1945 to 1955. Altogether, Vienna's population decreased by approximately 15 percent between 1934 and 1951. With the demise of communist regimes in eastern Europe in the late 1980s and early '90s, however, emigration to Vienna increased the city's population to more than 1,600,000, roughly the same figure as in 1900.

Vienna has a disproportionately large number of elderly, most of whom live alone in the older neighbourhoods. Characteristic of most major cities, however, Vienna's population is shifting outward to the periphery. Although Vienna has a low birth rate and a small average family size, new housing in the periphery helps to alleviate problems caused by the city's high percentage of pre-World War I residential buildings.

Ethnicity and language. The Viennese are the product of centuries of cross-fertilization between mountain and plain, between the Balkan strain from one direction and the Germanic from the other. As the names in Vienna's telephone directory indicate, the ancestors of one Viennese in three have come from Bohemia, one in five from Hungary, one in seven from Poland, and one in eight from the Balkan Peninsula. Along with those whose families migrated from Germany and other parts of Austria, this mixture makes up the melting pot of Vienna. With the influx of immigrants in the 1990s, Vienna's cultural melting pot once again flourished. At the beginning of the 21st century nearly one-fifth of the city's residents had been born in foreign countries.

Wienerisch, the Viennese speech and accent, reveals social levels and origins. It also demonstrates that the people of Vienna have in their time been governed by Romans, Italians, Spanish, French, Magyars, and Slavs and have absorbed Turkish and Yiddish words into their German tongue in a way that renders the original unrecognizable. Their speech is in many ways closer to that of their neighbours to the south and east than to the German north, and one of its functions is to announce that "we are different." If the people have any leaning toward pomposity, it is balanced by a habit of self-mockery, as expressed in their saying, "The situation is hopeless but not serious." The famed *Gemütlichkeit* (untranslatable but akin to "coziness"), upon which the city's tourist trade thrives, is—like the nostalgia for wine, women, and song—part of a sentimental image of the Viennese.

Religion. Vienna is the seat of a Roman Catholic archbishop and a Protestant bishop. Two-thirds of the city's population are Roman Catholic and only a very small percentage Protestant. (Considerable numbers profess no religion.) The number of practicing Roman Catholics, however, is estimated to be only a small percentage of the population; like other modern capitals, Vienna is highly secular.

Before World War II the Viennese Jewish minority, which numbered more than 160,000, played a prominent role in the city, culturally and economically. It is estimated that two-thirds of all Jews emigrated to escape the Nazi occupation. Except for a small remnant that survived, either in hiding or in the concentration camps, the remainder of the Jewish Viennese were exterminated by the Nazis. They now make up less than 1 percent of the population.

Margin note: Vienna's ethnic melting pot

THE ECONOMY

Although commerce and industry form the base of Vienna's economy, government and public administration on all levels is also a major employer in the Austrian capital. The federally owned theatres alone employ several thousand people. Tourism is also an important economic activity with some two million travelers visiting the city annually. Vienna provides approximately one-fourth of the jobs in the country and produces almost one-third of the gross national product. The steady reduction in numbers of active workers owing to the rising proportion of older people has necessitated the recruitment of a foreign labour force, working primarily in the service sector and in menial occupations.

Industry and trade. Vienna produces more than half of Austria's capital goods and almost half of its consumer goods. Leading industries include the manufacture of machinery (primarily electrical machinery and transportation equipment), electrical products, chemicals, and metal products. In the Vienna area oil processing, cement works, and brickmaking are important as well. Special Viennese products are silk, velvet, linen, ceramics, jewelry, scientific and musical instruments, watches, cutlery, leather goods, furniture, paper, and carpets. The service industries in Vienna, including banking, account for half of Austria's total employment in this sector. The proportion of white-collar workers, public employees, and civil servants in the total labour force continues to grow.

The Vienna international trade fair, which takes place twice a year in March and September, attracts exhibitors from both European and overseas countries and is attended by several hundred thousand visitors annually. Several hundred American, German, Japanese, and British firms, as well as many firms from eastern European countries, use Vienna as a base for trading operations. Approximately 10 percent of Austria's exports go to the eastern European countries.

Margin note: International trade fairs

Transportation. In the 19th century tens of thousands of immigrants from all parts of the Austro-Hungarian Empire arrived at Vienna's six major railway terminals. Today only two important stations are left, South Railway Station and West Railway Station. The city's busy international airport, Schwechat, is served by more than 30 airlines, and motorways radiate in all directions. Freight transport down the Danube to the Balkan states, Romania, and the Black Sea, and via the Rhine–Main–Danube Canal to northwestern Europe, has grown in importance.

After World War II Vienna chose to retain its tramway system instead of converting to buses. The old system, modernized and updated, continues to be an important low-cost form of public transportation. The extensive underground network has also been expanded. Consequently, within the city, most people travel by public transportation or on foot.

ADMINISTRATION AND SOCIAL CONDITIONS

Government. Because of the dual character of Vienna as the capital city and a federal state of the republic, the municipal and the state administration are in the hands of the same elected representatives acting in institutionally separate capacities. The affairs of the city's 23 municipal districts are managed by appointed magistrates, and the city is governed by a mayor, who is assisted by two deputies, and a city council composed of 100 members. The mayor, who is elected by the city council, also serves as the governor of the federal province. Representatives to the city council are elected every five years by proportional representation. Vienna sends 28 members to the National Council, the lower house of Austria's legislature, and 11 members to the Federal Council, the upper house.

The government not only runs the city but also operates a major business, the Vienna Holding, a combination of state and private enterprise. Its firms include low-cost restaurants, a major publishing house, an insurance company, a cold-storage depot, shopping centres, cinemas, and the large, multifunctional Stadthalle ("City Hall"), with a seating capacity of 16,000, for sporting events, concerts, dances, exhibitions, and swimming. The old Theater an der Wien and the traditional Viennese porcelain factory,

which was closed in 1864, were rescued from extinction by this enterprise.

Health and welfare. Vienna's hospitals and medical training have been widely esteemed since the mid-18th century. Emperor Joseph II founded the General Hospital in 1784, and in the 19th century Viennese medicine led the world. Vienna claims several renowned medical scientists, among them Ignaz Philipp Semmelweis, discoverer of the cause of puerperal fever; Theodor Billroth, a pioneer in abdominal surgery; Karl Landsteiner, discoverer of the blood groups; and Sigmund Freud, the founder of psychoanalysis.

For many reasons the city's public health care system is regarded as one of the world's best. The number of doctors in proportion to the population is high; there are more than 40 general and special hospitals and numerous geriatric facilities. In addition to providing model health services, the municipal government has been among the world's pioneers in public welfare and social insurance. Vienna is also renowned for its clean drinking water, which comes from springs in the mountains around the city.

Education. Vienna has a much higher proportion of high-school and university graduates than the other Austrian provinces. Of the 12 universities in the country, five are located in Vienna: the University of Vienna, the University of Technology, the University of Agriculture, the University of Veterinary Medicine, and the University of Economics in Vienna. Other notable institutions include the Academy of Music and Dramatic Art, the Academy of Fine Arts, and the Academy of Applied Arts. There are also a Roman Catholic academy, several scientific societies, and many research institutes, as well as the venerable Austrian Academy of Sciences. Vienna's teaching of music, medicine, law, and the arts attracts many foreign students, who make up about 10 percent of the total student population.

CULTURAL LIFE

Music and theatre. Vienna is the undisputed cultural centre of Austria and one of the world capitals of music. Even the Salzburg and Bregenz festivals are dependent on Viennese orchestras, musicians, theatre directors, and actors. Operas, concerts, and theatrical performances have played a major part in Viennese life for centuries, and many world-famous composers lived and worked in the city. The famous Society of Friends of Music, founded in 1812, helps to ensure that Vienna remains a leading music centre.

The Vienna Boys' Choir, founded in 1498 (Haydn and Schubert were its most famous boy members), sings on Sunday mornings at the mass in the Hofburg Chapel. The Vienna Philharmonic Orchestra gives frequent Saturday afternoon and Sunday morning concerts and also performs during the week at the State Opera House. Altogether there are seven concert halls in Vienna. Among the highlights of the Viennese musical calendar are the annual gala performance of Johann Strauss's operetta *Die Fledermaus* on New Year's Eve and the New Year's concert of the Philharmonic, broadcast and televised throughout the world.

The two major opera houses, the State Opera and the People's Opera, and the two leading theatres, the Burgtheater and the Academy Theatre, are owned by the Austrian federal government, and their singers and actors enjoy respected civil servant status. The State Opera is one of the leading opera houses in the world, where Verdi and Wagner conducted and where Gustav Mahler was director. It opened in 1869 with a performance of Mozart's *Don Giovanni.* During World War II it was destroyed, and, after rebuilding, it reopened in 1955 with a performance of Beethoven's *Fidelio.* The Burgtheater, founded in 1776, is one of the most highly regarded German-language theatres in Europe. In addition to several large theatres, Vienna has numerous small theatres, which provide a home for more avant-garde works.

Museums and libraries. Vienna has a wide variety of museums and historic houses. Among them are the Albertina, with its immense collection of graphic arts, including engravings by Dürer and Rembrandt; the Kunsthistorisches Museum with the largest Bruegel collection outside The Netherlands; the Academy of Fine Arts, housing the superb Habsburg collection of old masters, especially rich in Flemish and Dutch paintings; the Imperial Treasury, with the imperial crown and the regalia of the Holy Roman emperors and the house of Habsburg; the museums of natural history, ethnology, military history, and technology; the Clock Museum; and the Museum of the City of Vienna, with its exhibits of Viennese history.

The Roman excavations in the Hoher Market, converted into an underground museum; the catacombs of St. Stephen's Cathedral; the Imperial Vault in the Church of the Capuchins, burial place of the Habsburg emperors; and the exhibits and imperial apartments in the Schönbrunn Palace offer a historical dimension to the city's art treasures. The houses in which Haydn, Mozart, Beethoven, Schubert, and Johann Strauss lived and worked are open to the public. The apartment that was Sigmund Freud's home and office for nearly 50 years is also a museum.

In addition to its museums and historical sites, Vienna is notable for its libraries, including the National Library, the University Library, the City Library, and the libraries of the Natural History Museum and the Academy of Sciences.

Coffeehouses and taverns. The coffeehouse has been a Viennese institution for three centuries. According to legend, the first such establishment opened with an inventory of Turkish coffee beans, part of the booty from the Siege of Vienna in 1683. There are a variety of coffees and an assortment of supplements such as cream or brandy to choose from. The Viennese have turned the coffeehouse into a sort of second living room, where they not only drink their beverage and consume pastries but also read periodicals, play cards, and chat with friends. There were once famous literary and theatrical cafés where artists and famous personalities held court; still flourishing is the Café Demel, a true custodian of the past.

Also peculiar to Vienna are the taverns in which is served the young, sour wine—*Heuriger*—of the previous year's local harvest. Some of the most famous taverns are in the outlying districts of Vienna, such as Grinzing, Nussdorf, and Sievering, and they are identified by evergreen branches hung over the entrance. The wine drinking is accompanied with music, usually played by a trio of instruments, including those such as a fiddle, accordion, guitar, or zither.

History

THE ANCIENT CITY AND MEDIEVAL GROWTH

Traces of human occupation of the site of Vienna have been found dating as far back as the Paleolithic period. The area was subsequently inhabited by the Illyrians and then the Celts. In 16–15 BC the Romans, under the future emperor Tiberius, occupied the foothills of the Alps, and in the next century the Celtic town of Vindobona (Celtic: "White Field"; later to become Vienna) became a strategic Roman garrison town. (The Roman camp is believed to have covered the area around the present Hoher Market.) Vindobona grew to about 15,000 inhabitants and became part of a widespread network of trade and communications. Emperor Marcus Aurelius is said to have died in Vindobona in 180 AD fighting off attacks by the Germanic tribes. The Romans were swept away in the turmoil of the 5th-century invasions, but enough of Vindobona remained to serve as the nucleus of the medieval city. The Bavarians occupied the area, and the people became Christianized. The city's name was recorded in 881 as Wenia and in 1030 as Wienis.

The dukes of Babenberg, a Frankish dynasty, were overlords of Vienna from 1156 to 1246. The city developed into an important trading centre, where crusaders on their way to the East bought provisions and equipment. In the 13th century, walls were built around the city, and Vienna remained largely confined within the walled area until the 1700s. The Babenbergs kept a brilliant court and encouraged artists like the famous minnesinger Walther von der Vogelweide.

In 1246 the last male of the Babenberg family died. In the ensuing struggle for domination, the king of Bohemia,

Otakar II, became overlord of what was to become Austria. Otakar established himself as a powerful central European prince, and by 1276 he was at war with the German king, Rudolf 1 of the Habsburg dynasty. When Otakar fell in battle in 1278, the Habsburgs took over his domain and retained it for more than 600 years. The capital city flourished, trading with Trieste, Venice, and Hungary; nevertheless, economic decline attended the numerous disputes over inheritance within the Habsburg family. In 1485, under siege by Matthias 1 Corvinus of Hungary, the city fathers surrendered in the hope of bettering their status. When Corvinus died five years later, Vienna reverted to the Habsburg emperor, Frederick III.

DEVELOPMENT OF IMPERIAL VIENNA

During the Renaissance, Vienna was a leader in science and fine arts, and the university (1365) was a centre of humanism. When Charles V became Holy Roman emperor in the 16th century he entrusted his Austrian territories to his brother, the future emperor Ferdinand I. Seeking to increase their liberties and economic position, the Lower Austrian Diet rebelled against their regent. Ferdinand responded by condemning the leaders of the insurrection to death, and in 1526 he issued an ordinance that stripped the city of almost all its rights. In the same year, he inherited the kingdoms of Bohemia and Hungary and, accordingly, the task of fighting the Turks, who commanded large parts of Hungary. Turkish forces besieged Vienna in 1529 but were successfully beaten off. When Ferdinand was crowned emperor in 1558, Vienna regained its political status and became the administrative seat of numerous kingdoms that the Habsburgs acquired by marriage.

The Reformation swept through Europe during the 16th century, arousing heated opposition from the Roman Catholic church. In an attempt to stem the controversy, the imperial Diet, in the Peace of Augsburg (1555), recognized the right of Lutheranism to exist but decreed that the regional princes were to determine which form of Christianity their subjects must follow. Because the Viennese were required to remain Roman Catholic, many of the great number who had become Protestant had to leave the city. It was during this period that new fortifications were built to replace the medieval city walls and the Hofburg was enlarged with the addition of new courts. The splendid secular buildings of the Baroque era proclaimed Vienna's stature as an imperial residence and one of the great world capitals.

In 1679 the bubonic plague struck the city, killing nearly a third of its population. Then, during the summer of 1683, Vienna suffered a second Turkish siege, this one led by the grand vizier Kara Mustafa. The Viennese defenders, together with imperial troops under Charles of Lorraine, held off the Turkish army, which was defeated with the help of relief forces led by John III Sobieski, king of Poland. Shortly thereafter Prince Eugene of Savoy succeeded in driving the Turks out of Hungary.

With the Turkish threat at an end, there followed an upsurge of building, particularly in the devastated suburbs. Between 1700 and 1730 a city of palaces and stately homes emerged. A second line of fortifications, the *Linienwall* ("straight rampart"), was built in 1704–06 to give the suburbs protection. In the densely built-up Innere Stadt old houses either had upper stories added or were demolished and replaced by Baroque structures. Hildebrandt, J.B. Fischer von Erlach, and Fischer von Erlach's son Joseph Emanuel were the great Viennese architects of the time, and their achievements are still evident in some of the city's best buildings.

During this period, immigrants arrived from other parts of the empire, and new factories heralded the city's transition from trade to manufacturing. The arts also received fresh energy, as instanced by Joseph Anton Stranitzky's newly created Viennese Impromptu Theatre, which opened with the character masque of Hanswurst.

The male line of the Habsburgs died out with Charles VI in 1740, but by the terms of the Pragmatic Sanction his daughter Maria Theresa gained the right of succession and reigned until 1780. She established compulsory primary-school attendance; separated the university from the

church, bringing it under state control; and reorganized the economy, the army, and the judiciary. Her son and successor, Joseph II, was typical of the Enlightenment's absolute monarchs and continued in her reforming spirit. His Edict of Toleration guaranteed religious freedom to Protestants and Jews. He instituted many humanitarian measures, improved government and education, and supported the arts. Some of his actions, like the dissolution of the monasteries, brought him into conflict with the church. By the time Joseph died in 1790, there were 300 factories in Vienna, the population had increased to 235,-000, and the built-up area had increased 10-fold since the Turkish siege. Gluck, Haydn, and Mozart had ushered in Vienna's first golden age of music; Beethoven and Schubert would carry it into the next century.

In 1804 Francis II declared himself emperor of Austria and in 1806 resigned his former imperial crown, thus bringing to an end the Holy Roman Empire, which had long been essentially a German monarchy. Napoleon's armies occupied Vienna in 1805 and again in 1809. Inflation and state bankruptcy followed the Napoleonic Wars. Politically, however, Vienna held a central position in the restoration of Europe at the Congress of Vienna (1814–15) under the leadership of the powerful statesman Prince Metternich.

By 1845 Vienna had 430,000 inhabitants. The aspirations and cultural interests of the middle class were growing, finding artistic expression primarily in the simple and commonplace forms of the Biedermeier style of decoration and furniture design. Joseph Lanner and the elder Johann Strauss enlivened the city with Viennese waltzes. The revolution of March 1848 in Vienna brought to an end Metternich's authoritarian rule. A second uprising, in October, was put down by the imperial army of Francis Joseph. The city continued to grow culturally as the Austrian (later the Austro-Hungarian) imperial capital.

EVOLUTION OF THE MODERN CITY

Vienna's inner ramparts were razed in 1857 and the city ditches filled in. They were replaced by the Ringstrasse, opened in 1865. The stately public buildings and parks along this great avenue emerged over the years. In other parts of the city old structures were demolished and new ones built. The drinking-water supply was improved with springwater; the Danube was regulated; and, later, gas and electric works were built. New regulations in 1859 established full freedom of trade. Vienna's economy grew rapidly, and with it the city's population.

In 1861 Vienna was granted city self-government through a freely elected city council, which acquired a liberal majority. The suburbs were brought under the city administration in 1890. Three years later the *Linienwall* was dismantled and a second ring road, the Gürtel, built in its place. Musical Vienna flourished under the composers Brahms, Anton Bruckner, Hugo Wolf, and Mahler. Operetta became established as a characteristic Viennese art form through the music of the younger Johann Strauss, Franz von Suppé, Franz Lehár, and Emmerich Kálmán.

At the turn of the century, with nearly 2 million inhabitants and an area of 105 square miles, Vienna began to spread to the left bank of the Danube. The capital city had become a fertile breeding ground for ideas that—for good or bad—were to shape the modern world. Among the thousands who flocked to Vienna seeking work or a vocation was the young Adolf Hitler. Having failed there as an art student, he adopted notions of Greater German nationalism and was influenced by both the rhetorical style and the virulent anti-Semitism of Vienna's mayor, Karl Lueger. In contrast, Theodor Herzl, the founder of Zionism, was living in the city at the same time. In Vienna as well were Sigmund Freud and Alfred Adler, at work developing their far-reaching psychiatric theories.

Artistic activity reached new heights in the early 20th century. In architecture, painting, and design, the Sezessionstil (German: Jugendstil) movement (Art Nouveau) provided means for young artists to rebel against pretentiousness in the Viennese art establishment, including the style of architecture on the Ring. Otto Wagner, Adolf Loos, and Josef Hoffmann were prominent architects and

Peace of Augsburg

The Turkish siege

Musical pioneers

Revolution in the arts

designers of the new school; among the painters were Gustav Klimt, Alfred Kubin, Oskar Kokoschka, and Egon Schiele. Viennese music continued to break new ground with the works of Arnold Schoenberg, Alban Berg, and Anton von Webern. Influential writers included Arthur Schnitzler, Hugo von Hofmannsthal, and Karl Kraus.

During World War I the city's population swelled to 2,239,000 with an influx of refugees. Francis Joseph died in 1916; his successor, Charles, was forced to abdicate at the end of the war. The Habsburg monarchy fell, and a German-Austrian republic was proclaimed in November 1918. In 1919 general suffrage produced a Social Democratic majority in the city council. The party introduced numerous reforms in housing, education, public welfare, and health care. The city became recognized internationally as a forerunner of the modern welfare state. In 1922 Vienna was made a federal province of Austria, the mayor of the city also serving as the governor of the province.

Economically and politically the young republic was on shaky ground. The Social Democrats (Marxist) and their Christian Social (conservative) opponents carried politics into the streets and trained their own armies. Mass political demonstrations were answered with savage repression, and in 1933 the Austrian chancellor, Engelbert Dollfuss, dissolved Parliament and set up an authoritarian regime. His government's decision to fire upon Viennese workers defending their apartment blocks (1934) was seen by many as a final betrayal of democracy. Disillusioned with party politics and drawn toward their fellow countryman Adolf Hitler in neighbouring Germany, many Austrians adopted the old idea that they were not only linguistically but also politically German and ought to unite with Germany. On March 12, 1938, the German army occupied Austria. A few days later, Hitler proclaimed the Anschluss; Greater Vienna, now including the province of Lower Austria, became a German province.

The Austrians soon became disenchanted with their new masters and, while fighting with Germany in World War II, developed a new sense of independence and nationhood. In April 1945 Vienna was taken by Soviet troops. In September the city, like the country as a whole, was divided into four zones of occupation by the Allied powers. Vienna emerged from the war with nearly a quarter of its buildings either partially or completely destroyed. The city's population had fallen to 1,322,000. The immense task of providing food and shelter, repairing the transportation network, and rebuilding the city began under the

mayors Theodor Körner (1945–51) and Franz Jonas (1951–65), both of whom later became presidents of the republic. The Austrian State Treaty was signed in the Belvedere on May 15, 1955, leading to independence and the withdrawal of all Allied occupation troops.

Vienna's geographic position at the heart of Europe was devalued three times in the 20th century: in 1918, when it became the top-heavy capital of a small republic; in 1938, when the takeover by Germany reduced it to a German province; and in 1945, when the Iron Curtain came down some 50 miles to the east. But to a large extent the city remains a focal point of East–West contacts. A neutral state since 1955, Vienna has nonetheless become important as a major international meeting place and conference centre. On the outskirts of Vienna, across the Danube, the modern buildings of the Vienna International Centre, or UNO-City, include the offices of the International Atomic Energy Agency, the United Nations Industrial Development Organization, and the Organization of Petroleum Exporting Countries. With the rise of the UNO-City, Vienna has become competitive with New York City and Geneva as a seat of world organizations.

With the democratic transformation in eastern Europe in the 1990s, Vienna once again became a more central location in Europe. Its role as a crossroad hub will likely increase as membership in the European Union, which Austria joined in 1995, expands eastward.

The Vietnam War

The Vietnam War (1954–75) was a protracted conflict that pitted the communist government of North Vietnam and its allies in South Vietnam, known as the Viet Cong, against the government of South Vietnam and its principal ally, the United States. It is called the "American War" in Vietnam (or, in full, the "War Against the Americans to Save the Nation"). At the heart of the conflict was the desire of North Vietnam, which had defeated the French colonial administration in 1954, to unify the entire country under a single communist regime modeled after those of the Soviet Union and China. The South Vietnamese government, on the other hand, fought to preserve a Vietnam more closely aligned with the West. U.S. military advisers, present in small numbers throughout the 1950s, were introduced on a large scale beginning in 1961, and active combat units were introduced in 1965. By 1969 more than 500,000 U.S. military personnel were stationed in Vietnam. Meanwhile, the Soviet Union and China poured weapons, supplies, and advisers into the North, which in turn provided support, political direction, and regular combat troops for the campaign in the South. The costs and casualties of the growing war proved too much for the United States to bear, and U.S. combat units were withdrawn by 1973. In 1975 South Vietnam fell to a full-scale invasion by the North.

The human costs of the long conflict were harsh for all involved. Not until 1995 did Vietnam release its official estimate of war dead: as many as 2 million civilians on both sides and some 1.1 million North Vietnamese and Viet Cong fighters. The U.S. military has estimated that between 200,000 and 250,000 South Vietnamese soldiers died in the war. In 1982 the Vietnam Veterans Memorial was dedicated in Washington, D.C., inscribed with the names of 57,939 members of U.S. armed forces who had died or were missing as a result of the war. Over the following years, additions to the list have brought the total past 58,200. (At least 100 names on the memorial are those of servicemen who were actually Canadian citizens.) Among other countries that fought for South Vietnam on a smaller scale, South Korea suffered more than 4,000 dead, Thailand about 350, Australia more than 500, and New Zealand some three dozen. (Ed.)

This article is divided into the following sections:

French rule ended, Vietnam divided

The Vietnam War had its origins in the broader Indochina wars of the 1940s and '50s, when nationalist groups such as Ho Chi Minh's Viet Minh, inspired by Chinese and Soviet communism, fought the colonial rule first of Japan and then of France. The French Indochina War broke out in 1946 and went on for eight years, with France's war effort largely funded and supplied by the United States. Finally, with their shattering defeat by the Viet Minh at the Battle of Dien Bien Phu in May 1954, the French came to the end of their rule in Indochina. The bat-

tle prodded negotiators at the Geneva Conference to produce the final Geneva Accords in July 1954. The accords established the 17th parallel (latitude 17° N) as a temporary demarcation line separating the military forces of the French and the Viet Minh. North of the line was the Democratic Republic of Vietnam, or North Vietnam, which had waged a successful eight-year struggle against the French. The North was under the full control of the Worker's Party, or Vietnamese Communist Party, led by Ho Chi Minh; its capital was Hanoi. In the South the French transferred most of their authority to the State of Vietnam, which had its capital at Saigon and was nominally under the authority of the former Vietnamese emperor, Bao Dai. Within 300 days of the signing of the Accords, a demilitarized zone, or DMZ, was to be created by mutual withdrawal of forces north and south of the 17th parallel, and the transfer of any civilians who wished to leave either side was to be completed. Nationwide elections to decide the future of Vietnam, North and South, were to be held in 1956.

Accepting the de facto partition of Vietnam as unavoidable but still pledging to halt the spread of communism in Asia, U.S. President Dwight D. Eisenhower began a crash program of assistance to the State of Vietnam—or South Vietnam, as it was invariably called. At the same time, Viet Minh leaders, confidently expecting political disarray and unrest in the South, retained many of their political operatives and propagandists below the 17th parallel even as they withdrew their military forces to the North. Ngo Dinh Diem, the newly installed premier of South Vietnam, thus faced opposition not only from the communist regime in the North but also from the Viet Minh's stay-behind political agents, armed religious sects in the South, and even subversive elements in his own army. Yet Diem had the full support of U.S. military advisers, who trained and reequipped his army along American lines and foiled coup plots by dissident officers. Operatives of the U.S. Central Intelligence Agency (CIA) bought off or intimidated Diem's domestic opposition, and U.S. aid agencies helped him to keep his economy afloat and to resettle some 900,000 refugees who had fled the communist North.

By late 1955 Diem had consolidated his power in the South, defeating the remaining sect forces and arresting communist operatives who had surfaced in considerable numbers to prepare for the anticipated elections. Publicly opposed to the elections, Diem called for a referendum only in the South, and in October 1955 he declared himself president of the Republic of Vietnam. The North, not ready to start a new war and unable to induce its Chinese or Russian allies to act, could do little.

U.S. aid under Eisenhower

The Diem regime and the Viet Cong

Leaders in the U.S. capital, Washington, D.C., were surprised and delighted by Diem's success. American military and economic aid continued to pour into South Vietnam while American military and police advisers helped train and equip Diem's army and security forces. Beneath the outward success of the Diem regime, however, lay fatal problems. Diem was a poor administrator who refused to delegate authority, and he was pathologically suspicious of anyone who was not a member of his family. In the countryside, ambitious programs of social and economic reform had been allowed to languish while many local officials and police engaged in extortion, bribery, and theft of government property. That many of these officials were, like Diem himself, northerners and Roman Catholics further alienated them from the local people.

Diem's unexpected offensive against communist political organizers and propagandists in the countryside in 1955

had resulted in the arrest of thousands and in the temporary disorganization of the communists' infrastructure. By 1957, however, the communists, now called the Viet Cong, had begun a program of terrorism and assassination against government officials and functionaries. The Viet Cong's ranks were soon swelled by many noncommunist Vietnamese who had been alienated by the corruption and intimidation of local officials. Beginning in the spring of 1959, armed bands of Viet Cong were occasionally engaging units of the South Vietnamese army in regular firefights. By that time the Central Committee of the Vietnamese Communist Party, meeting in Hanoi, had endorsed a resolution calling for the use of armed force to overthrow the Diem government. Southerners specially trained in the North as insurgents were infiltrated back into the South along with arms and equipment. A new war had begun.

Despite its American training and weapons, the Army of the Republic of Vietnam, usually called the ARVN, was in many ways ill-adapted to meet the insurgency of the Viet Cong, or VC. Higher-ranking officers, appointed on the basis of their family connections and political reliability, were often apathetic, incompetent, or corrupt—and sometimes all three. The higher ranks of the army were also thoroughly penetrated by Viet Cong agents, who held positions varying from drivers, clerks, and radio operators to senior headquarters officers. With its heavy American-style equipment, the ARVN was principally a road-bound force not well configured to pursuing VC units in swamps or jungles. U.S. military advisers responsible for helping to develop and improve the force usually lacked knowledge of the Vietnamese language, and in any case they routinely spent less than 12 months in the country.

Organization of the communist forces

At the end of 1960 the communists in the South announced the formation of the National Liberation Front (NLF), which was designed to serve as the political arm of the Viet Cong and also as a broad-based organization for all those who desired an end to the Diem regime. The Front's regular army, usually referred to as the "main force" by the Americans, was much smaller than Diem's army, but it was only one component of the Viet Cong's so-called People's Liberation Armed Forces (PLAF). At the base of the PLAF were village guerrilla units, made up of part-time combatants who lived at home and worked at their regular occupations during the day. Their function was to persuade or intimidate their neighbours into supporting the NLF, to protect its political apparatus, and to harass the government, police, and security forces with booby traps, raids, kidnappings, and murders. The guerrilla forces also served as a recruiting agency and source of manpower for the other echelons of the PLAF. Above the guerrillas were the local or regional forces, full-time soldiers organized in platoon- or company-sized units who operated within the bounds of a province or region. As members of the guerrilla militia gained experience, they might be upgraded to the regional or main forces, which were better-equipped. Based in remote jungles, swamps, or mountainous areas, they could operate throughout a province (in the case of regional forces) or even the country (in the case of the main force). When necessary, the full-time forces might also reinforce a guerrilla unit or several units for some special operation.

The U.S. role grows

By the middle of 1960 it was apparent that the South Vietnamese army and security forces could not cope with the new threat. During the last half of 1959, VC-initiated ambushes and attacks on posts averaged well over 100 a month. In the next year 2,500 government functionaries and other real and imagined enemies of the Viet Cong were assassinated. It took some time for the new situation to be recognized in Saigon and Washington. Only after four VC companies had attacked and overrun an ARVN regimental headquarters northeast of Saigon in January 1960 did Americans in Vietnam begin to plan for increased U.S. aid to Diem. They also began to search for ways to persuade Diem to reform and reorganize his government—a search that would prove futile.

To the new administration of U.S. President John F. Kennedy, who took office in 1961, Vietnam represented both a challenge and an opportunity. The Viet Cong's armed struggle against Diem seemed to be a prime example of the new Chinese and Soviet strategy of encouraging and aiding "wars of national liberation" in newly independent nations of Asia and Africa—in other words, helping communist-led insurgencies to subvert and overthrow the shaky new governments of emerging nations. Kennedy and some of his close advisers believed that Vietnam presented an opportunity to test the United States' ability to conduct a "counterinsurgency" against communist subversion and guerrilla warfare. A successful effort in Vietnam—in Kennedy's words, "the cornerstone of the free world in Southeast Asia"—would provide to both allies and adversaries evidence of U.S. determination to meet the challenge of communist expansion in the Third World.

Kennedy's foreign policy

Though never doubting Vietnam's importance, the new president was obliged, during much of his first year in office, to deal with far more pressing issues—the construction of the Berlin Wall, conflicts between the Laotian government and the communist-led Pathet Lao, and the humiliating failure of the Bay of Pigs invasion of Cuba. Because of these other, more widely known crises, it seemed to some of Kennedy's advisers all the more important to score some sort of success in Vietnam. Success seemed urgently needed as membership in the NLF continued to climb, military setbacks to the ARVN continued, and the rate of infiltration from the North increased. U.S. intelligence estimated that in 1960 about 4,000 communist cadres infiltrated from the North; by 1962 the total had risen to some 12,900. Most of these men were natives of South Vietnam who had been regrouped to the North after Geneva. More than half were Communist Party members. Hardened and experienced leaders, they provided a framework around which the PLAF could be organized. To arm and equip their growing forces in the South, Hanoi leaders sent crew-served weapons and ammunition in steel-hulled motor junks down the coast of Vietnam and also through Laos via a network of tracks known as the Ho Chi Minh Trail. But most of the firearms for PLAF soldiers actually came from the United States: large quantities of American rifles, carbines, machine guns, and mortars were captured from Saigon's armed forces or simply sold to the Viet Cong by Diem's corrupt officers and functionaries.

As the situation continued to deteriorate, Kennedy sent two key advisers, economist W.W. Rostow and former army chief of staff Maxwell Taylor, to Vietnam in the fall of 1961 to assess conditions. The two concluded that the South Vietnamese government was losing the war with the Viet Cong and had neither the will nor the ability to turn the tide on its own. They recommended a greatly expanded program of military assistance, including such items as helicopters and armoured personnel carriers, and an ambitious plan to place American advisers and technical experts at all levels and in all agencies of the Vietnamese government and military. They also recom-

South Vietnamese soldiers with Viet Cong prisoners in the Mekong delta, 1962.

mended the introduction of a limited number of U.S. combat troops, a measure the Joint Chiefs of Staff had been urging as well.

More U.S. advisers

Well aware of the domestic political consequences of "losing" another country to the communists, Kennedy could see no viable exit from Vietnam, but he also was reluctant to commit combat troops to a war in Southeast Asia. Instead, the administration proceeded with vigour and enthusiasm to carry out the expansive program of aid and guidance proposed in the Rostow-Taylor report. A new four-star general's position—commander, U.S. Military Assistance Command Vietnam (USMACV)—was established in Saigon to guide the military assistance effort. The number of U.S. military personnel in Vietnam, less than 800 throughout the 1950s, rose to about 9,000 by the middle of 1962.

The conflict deepens

Buoyed by its new American weapons and encouraged by its aggressive and confident American advisers, the South Vietnamese army took the offensive against the Viet Cong. At the same time, the Diem government undertook an extensive security campaign called the Strategic Hamlet Program. The object of the program was to concentrate rural populations into more defensible positions where they could be more easily protected and segregated from the Viet Cong. The hamlet project was inspired by a similar program in Malaya, where local farmers had been moved into so-called New Villages during a rebellion by Chinese Malayan communists in 1948–60. In the case of Vietnam, however, it proved virtually impossible to tell which Vietnamese were to be protected and which excluded. Because of popular discontent with the compulsory labour and frequent dislocations involved in establishing the villages, many strategic hamlets soon had as many VC recruits inside their walls as outside.

Meanwhile, the Viet Cong learned to cope with the ARVN's new array of American weapons. Helicopters proved vulnerable to small-arms fire, while armoured personnel carriers could be stopped or disoriented if their exposed drivers or machine gunners were hit. The communists' survival of many military encounters was helped by the fact that the leadership of the South Vietnamese army was as incompetent, faction-ridden, and poorly trained as it had been in the 1950s. In January 1963 a Viet Cong battalion near the village of Ap Bac in the Mekong delta south of Saigon, though surrounded and outnumbered by ARVN forces, successfully fought its way out of its encirclement, destroying five helicopters and killing about 80 South Vietnamese soldiers and three American advisers. By now some aggressive American newsmen were beginning to report on serious deficiencies in the U.S. advisory and support programs in Vietnam, and some advisers at lower levels were beginning to agree with them; but by now there was also a large and powerful bureaucracy in Saigon that had a deep stake in ensuring that U.S. programs appeared successful. The USMACV commander Paul Harkins and U.S. ambassador Frederick Nolting in particular continued to assure Washington that all was going well.

By the summer of 1963, however, there were growing doubts about the ability of the Diem government to prosecute the war. In May 1963 a fatal quarrel with the Buddhist leadership began. Strikes and demonstrations by Buddhists in Saigon and Hue were met with violence by the army and security forces and resulted in numerous arrests. The following month a Buddhist monk, Thich Quang Duc, publicly doused himself with gasoline and set himself ablaze as a protest against Diem's repression. Sensational photographs of that event were on the front pages of major American newspapers the following morning.

By now many students and members of the professional classes in South Vietnamese cities had joined the Buddhists. After a series of brutal raids by government forces on Buddhist pagodas in August, a group of South Vietnamese generals secretly approached the U.S. government to determine how Washington might react to a coup to remove Diem. The U.S. reply was far from discouraging, but

it was not until November, after further deterioration in Diem's relations with Washington, that the generals felt ready to move. On November 1, ARVN units seized control of Saigon, disarmed the security forces, and occupied the presidential palace. The American attitude was officially neutral, but the U.S. embassy maintained contact with the dissident generals while making no move to aid Diem, who was captured and murdered by the army.

Diem overthrown

Diem's death was followed by Kennedy's less than three weeks later. With regard to Vietnam, the assassinated president left his successor, Lyndon B. Johnson, a legacy of indecision, half-measures, and gradually increasing involvement. Kennedy had relished Cold War challenges; Johnson did not. A veteran politician and one of the ablest men ever to serve in the U.S. Senate, he had an ambitious domestic legislative agenda that he was determined to fight through Congress. Foreign policy crises would be at best a distraction and at worst a threat to his domestic reforms. Yet Johnson, like Kennedy, was also well aware of the high political costs of "losing" another country to communism. He shared the view of most of his advisers, many of them holdovers from the Kennedy administration, that Vietnam was also a key test of U.S. credibility and ability to keep its commitments to its allies. Consequently, Johnson was determined to do everything necessary to carry on the American commitment to South Vietnam. He replaced Harkins with General William Westmoreland, a former superintendent of the U.S. Military Academy at West Point, and increased the number of U.S. military personnel still further—from 16,000 at the time of Kennedy's death in November 1963 to 23,000 by the end of 1964.

The Gulf of Tonkin

While Kennedy had at least the comforting illusion of progress in Vietnam (manufactured by Harkins and Diem), Johnson faced a starker picture of confusion, disunity, and muddle in Saigon and of a rapidly growing Viet Cong in the countryside. Those who had expected that the removal of the unpopular Diem would lead to unity and a more vigorous prosecution of the war were swiftly disillusioned. A short-lived military junta was followed by a shaky dictatorship under General Nguyen Khanh in January 1964.

In Hanoi, communist leaders, believing that victory was near, decided to make a major military commitment to winning the South. Troops and then entire units of the North Vietnamese Army (NVA) were sent south through Laos along the Ho Chi Minh Trail, which was by that time becoming a network of modern roads capable of handling truck traffic. Chinese communist leader Mao Zedong strongly supported the North Vietnamese offensive and promised to supply weapons and technical and logistical personnel. The Soviets, though now openly hostile to China, also decided to send aid to the North.

Hanoi committed to victory

With the South Vietnamese government in disarray, striking a blow against the North seemed to the Americans to be the only option. By the summer of 1964 the Pentagon had developed a plan for air strikes against selected targets in North Vietnam designed to inflict pain on the North and perhaps retard its support of the war in the South. To make clear the U.S. commitment to South Vietnam, some of Johnson's advisers urged him to seek a congressional resolution granting him broad authority to take action to safeguard U.S. interests in Southeast Asia. Johnson, however, preferred to shelve the controversial issue of Vietnam until after the November election.

An unexpected development in August 1964 altered that timetable. On August 2 the destroyer USS *Maddox* was attacked by North Vietnamese torpedo boats while on electronic surveillance patrol in the Gulf of Tonkin. The preceding day, patrol boats of the South Vietnamese navy had carried out clandestine raids on the islands of Hon Me and Hon Nieu just off the coast of North Vietnam, and the North Vietnamese may have assumed that the *Maddox* was involved. In any case, the U.S. destroyer suffered no damage, and the North Vietnamese boats were driven off by gunfire from the *Maddox* and from aircraft based on a nearby carrier.

President Johnson reacted to news of the attack by announcing that the U.S. Navy would continue patrols in the gulf and by sending a second destroyer, the *Turner Joy*, to join the *Maddox*. On the night of August 4 the two ships reported a second attack by torpedo boats. Although the captain of the *Maddox* soon cautioned that evidence for the second incident was inconclusive, Johnson and his advisers chose to believe those who insisted that a second attack had indeed taken place. The president ordered retaliatory air strikes against North Vietnamese naval bases, and he requested congressional support for a broad resolution authorizing him to take whatever action he deemed necessary to deal with future threats to U.S. forces or U.S. allies in Southeast Asia. The measure, soon dubbed the Gulf of Tonkin Resolution, passed the Senate and House overwhelmingly on August 7. Few who voted for the resolution were aware of the doubts concerning the second attack, and even fewer knew of the connection between the North Vietnamese attacks and U.S.-sponsored raids in the North or that the *Maddox* was on an intelligence mission. Although what many came to see as Johnson's deceptions would cause problems later, the immediate result of the president's actions was to remove Vietnam as an issue from the election campaign. In November Johnson was reelected by a landslide.

Gulf of Tonkin Resolution

The United States enters the war

Between the Gulf of Tonkin Resolution and the U.S. presidential election in November 1964, the situation in Vietnam had changed for the worse. Beginning in September, the Khanh government was succeeded by a bewildering array of cliques and coalitions, some of which stayed in power less than a month. In the countryside even the best ARVN units seemed incapable of defeating the main forces of the Viet Cong. The communists were now deliberately targeting U.S. military personnel and bases, beginning with a mortar attack on the U.S. air base at Bien Hoa near Saigon in November.

Many of Johnson's advisers now began to argue for some sort of retaliation against the North. Except for Undersecretary of State George Ball, all the president's civilian aides and principal military advisers believed in the efficacy of a bombing campaign; they differed only as to how it should be conducted. The military favoured a short and sharp campaign intended to cripple the North's war-making capabilities. On the other hand, National Security Adviser McGeorge Bundy and Assistant Secretary of Defense John McNaughton argued for a series of graduated air attacks that would become progressively more damaging until the North Vietnamese decided that the cost of waging war in the South was too high. Within the administration, both Ball and Vice President Hubert H. Humphrey warned the president that a major bombing campaign would likely lead only to further American commitment and political problems at home. But Johnson was more concerned with the immediate need to take action in order to halt the slide in Saigon. In mid-February, without public announcement, the United States began a campaign of sustained air strikes against the North that were code-named Rolling Thunder.

The bombing campaign followed the graduated path outlined by Bundy but was steadily expanded to include more targets and more frequent attacks. It was closely directed from the White House in order to avoid provoking the Chinese or Soviets through such actions as attacking ports where Soviet ships might be docked or hitting targets near the Chinese border. Yet it was soon apparent that the bombing would have little direct impact on the struggle in South Vietnam, where the communists appeared to be gaining ground inexorably. By June 1965 Westmoreland was predicting the likely collapse of the South Vietnamese army, and he recommended the rapid dispatch of U.S. troops to undertake offensive missions against the Viet Cong and North Vietnamese anywhere in South Vietnam. Secretary of Defense Robert S. McNamara, on a mission to Vietnam in early July, confirmed the need for additional forces. In late July Johnson took the final steps that would commit the United States to full-scale war in Vietnam: he authorized the dispatch of 100,000 troops immediately and an additional 100,000 in 1966. The president publicly announced his decisions at a news conference at the end of July. There was no declaration of war—not even an address to Congress—and no attempt to put the country on a war footing economically. The National Guard and military reserves were not called to active service, even though such a measure had long been part of the military's mobilization plans.

Johnson commits to full-scale war

Firepower comes to naught

Although Johnson and his advisers had painstakingly examined the question of committing military forces to Vietnam—how many should be sent and when—they had given little thought to the question of what the troops might do once they arrived. In contrast to the tightly controlled air war in the North, conduct of the ground war in the South was largely left to the leadership of General Westmoreland. Westmoreland commanded all U.S. operations in the South, but he was reluctant to press for a unified U.S. and South Vietnamese command despite the questionable capabilities of many South Vietnamese generals. Instead, the two allies depended on "coordination" and a continuation of the existing advisory relationship, with every South Vietnamese army unit larger than a com-

pany having its complement of U.S. advisers. At the top of the hierarchy, Westmoreland himself served as senior adviser to the chief of the Vietnamese Joint General Staff, General Cao Van Vien. The chronic political instability in Saigon seemed finally to have abated with the installation in February 1965 of a government headed by the army general Nguyen Van Thieu as head of state and air force general Nguyen Cao Ky as prime minister. This arrangement, backed by most of the top military commanders, lasted until 1968, when Ky was eased out of power, leaving Thieu in sole control.

Whatever the status of the South Vietnamese forces, they were clearly relegated to a secondary role as U.S. troops and equipment poured into the country. To support these forces, the Americans constructed an enormous logistical infrastructure that included four new jet-capable air bases with 10,000-foot (3,000-metre) runways, six new deepwater ports, 75 tactical air bases, 26 hospitals, and more than 10,000,000 square feet (900,000 square metres) of warehousing. By the fall of 1965, U.S. Marines and soldiers had clashed with NVA and VC main-force troops in bloody battles on the Batangan Peninsula south of Da Nang and in the Ia Drang valley in the central highlands. The U.S. forces employed their full panoply of firepower, including air strikes, artillery, armed helicopters, and even B-52 bombers, to inflict enormous losses on the enemy. Yet the communists believed they had more than held their own in these battles, and they were encouraged by the fact that they could easily reoccupy any areas they might have lost once the Americans pulled out.

U.S. strategy of attrition

Westmoreland's basic assumption was that U.S. forces, with their enormous and superior firepower, could best be employed in fighting the enemy's strongest units in the jungles and mountains, away from heavily populated areas. Behind this "shield" provided by the Americans, the South Vietnamese army and security forces could take on local Viet Cong elements and proceed with the job of reasserting government control in the countryside. Meanwhile, the regular forces of the Viet Cong and the NVA would continue to suffer enormous casualties at the hands of massive U.S. firepower. Eventually, went the argument, the communists would reach the point where they would no longer be able to replace their losses on the battlefield. Having been ground down on the battlefield, they would presumably agree to a favourable peace settlement.

That point seemed very distant to most Americans as the war continued into 1966 and 1967. Washington declared that the war was being won, but American casualties continued to mount, and much of what the public could see of the war on television appeared confusing if not futile. Because Westmoreland's strategy was based on attrition, one of the ways to measure progress was to track the number of enemy killed. The resultant "body count," which was supposed to be carried out by troops during or immediately after combat, soon became notorious for inaccuracy and for the tendency of U.S. commanders to exaggerate the figures.

In the provinces just north and east of Saigon, some large-scale operations such as Cedar Falls and Junction City, involving up to a thousand U.S. troops supported by hundreds of sorties by helicopters and fighter-bombers, were mounted to destroy communist base areas and supplies. Though yielding large quantities of captured weapons and supplies, they were ultimately indecisive, because the U.S. forces would invariably withdraw when they had completed their sweeps and in due course the Viet Cong and NVA would return. In order to deny the NVA and Viet Cong the use of dense forest to conceal their movements and to hide their supply lines and bases, the U.S. Air Force sprayed millions of gallons of a herbicide called Agent Orange along the Vietnamese border with Laos and Cambodia, in areas northwest of Saigon, and along major waterways. Agent Orange was effective in killing vegetation, but only at the price of causing considerable ecological damage to Vietnam and of exposing thousands of people to potentially toxic chemicals that would later cause serious and sometimes fatal health problems.

Along the DMZ separating North and South Vietnam, the Americans established a string of fortified bases ex-tending from just north of Quang Tri on the South China Sea westward to the Laotian border. These bases were part of a system that also included electronic warning devices, minefields, and infrared detectors designed to check infiltration or outright invasion from the North. The North Vietnamese, pleased to find that the strong-point obstacle system was within range of their artillery, carried out periodic attacks by fire and ground forces against U.S. outposts at Con Thien, Gio Linh, Camp Carroll, and Khe Sanh.

Bases on the DMZ

These larger engagements attracted most of the public's attention, but they were not in fact typical of the war in South Vietnam. Most "battles" of the war were sharp, very brief engagements between units of fewer than 200 men. Many of these lasted only a few hours, often only a few minutes, but nevertheless could result in heavy casualties. Overall, communist casualties far outnumbered U.S. casualties, but the North Vietnamese never came close to depleting their manpower. In any case, the communists could, when necessary, ease the pressure on themselves by withdrawing their forces to sanctuaries in nearby Laos, Cambodia, and North Vietnam. Hanoi, not Washington, largely controlled the tempo of the ground war.

Like the ground war in the South, the air campaign against the North continued to grow in scope and destructiveness but remained indecisive. By the end of 1966, the United States had dropped more bombs on North Vietnam than it had dropped on Japan during World War II and more than it had dropped during the entire Korean War. Yet the bombing seemed to have little impact on the communists' ability to carry on the war. North Vietnam was primarily an agricultural country with few industries to destroy. Many of the necessities of Hanoi's war effort came directly from China and the Soviet Union, which competed with each other to demonstrate support for Ho Chi Minh's "heroic" war against U.S. imperialism. The Soviets provided an estimated 1.8 billion rubles in military and economic aid and sent 3,000 military advisers and technicians along with sophisticated weapons to the North. China spent an estimated two billion dollars in assisting Hanoi; at the height of its effort, it had more than 300,000 engineering, medical, and anti-aircraft artillery troops in the Democratic Republic of Vietnam. Even when bombing knocked out more than 80 percent of the North's petroleum-storage facilities during the summer of 1966, the CIA reported no discernible shortages of petroleum or disruption of transportation. While the air raids continued, North Vietnam progressively strengthened its air defenses with the help of the latest radars, anti-aircraft guns, missiles, and modern jet fighters supplied by the Soviets and Chinese. By the end of 1966 the United States had already lost almost 500 aircraft and hundreds of air crewmen killed or held as prisoners of war.

Tet brings the war home

By 1967 growing numbers of Americans were becoming increasingly dissatisfied with the war. Some, especially students, intellectuals, academics, and clergymen, opposed the war on moral grounds, pointing out that large numbers of civilians in both the North and the South were becoming the chief victims of the war and that the United States was in reality supporting a corrupt and oppressive dictatorship in Saigon. Campus protests became common, and youthful picketers sometimes ringed the White House chanting, "Hey, hey, LBJ, how many kids did you kill today?" In October 1967 at least 35,000 demonstrators staged a mass protest outside the Pentagon. Many more Americans, not part of any peace movement, opposed the war because of the increasing American casualties and the lack of evidence that the United States was winning. Still other Americans believed that Johnson was not doing what was necessary to win the war and was obliging the military to fight "with one hand tied behind its back." By the summer of 1967 less than 50 percent of polled citizens said they supported the president's conduct of the war.

Growing antiwar movement in the United States

In Hanoi the communist leadership was also becoming impatient with the progress of the war. Although pleased with their ability to hold their own against the more numerous and better-armed Americans and their South Viet-

namese allies, they were aware that the United States showed no sign of giving up its hopes of victory and indeed had continued to pour more troops into Vietnam. In the summer of 1967 the communists decided on a bold stroke that would cripple the Saigon government and destroy once and for all American expectations of success. Their plan was to launch simultaneous military attacks at cities, towns, and military installations, combined with popular uprisings throughout the country. The "general offensive/general uprising" was scheduled to occur during the lunar New Year festival, or Tet, early in 1968.

To distract attention from their preparations and attract U.S. forces away from the large cities, the communists launched diversionary attacks in October 1967 against the important but isolated town of Dak To in the central highlands and against Loc Ninh on the route to Saigon. Finally, beginning in late January 1968, two North Vietnamese divisions began a prolonged offensive against the Marine base at Khe Sanh, in the northwest corner of South Vietnam near the Laotian border. News reports repeatedly drew comparisons between Khe Sanh and the siege of the French fortress at Dien Bien Phu. Both the president and General Westmoreland were convinced that Khe Sanh was the enemy's main objective and that signs of a communist buildup in the urban areas were merely a diversion.

Exactly the opposite was the case. On January 31, while approximately 50,000 U.S. and South Vietnamese troops were occupied in defending or supporting Khe Sanh and other DMZ bases, the communists launched an offensive throughout South Vietnam. They attacked 36 of 44 provincial capitals, 64 district capitals, five of the six major cities, and more than two dozen airfields and bases. Westmoreland's Saigon headquarters came under attack, and a VC squad even penetrated the compound of the U.S. embassy. In Hue, the former imperial Vietnamese capital, communist troops seized control of more than half the city and held it for nearly three weeks.

Although taken by surprise, U.S. and South Vietnamese forces struck back quickly against the often poorly coordinated attacks. With the exception of Hue, the communists were unable to hold any town or base for more than a day or two, and their forces suffered extremely heavy casualties. South Vietnamese soldiers, often defending their homes and families, fought surprisingly well, and nowhere did the population rise up to support the Viet Cong. Indeed, so destructive were some communist attacks that many in the local population, while still disliking the Saigon government, became far less supportive of the Viet Cong.

America shocked by Tet

U.S. and South Vietnamese troops may have recovered quickly, but that was not true of Americans at home. The Tet Offensive sent shock waves throughout the United States, startling those who had believed the White House's claims that victory was near and convincing those with doubts that the situation was even worse than they had imagined. Television coverage of the destructive fighting in Saigon and Hue was extensive and graphic and left many with the impression that the United States and its ally were in desperate straits. Many in Washington still expected a major battle at Khe Sanh or further large communist attacks elsewhere.

As criticism of Johnson's leadership by political leaders and the media mounted, the public was shocked to read in a *New York Times* headline story on March 10 that General Westmoreland had requested 206,000 additional troops for Vietnam. This news was widely interpreted as confirmation that the U.S. situation in Vietnam must be dire indeed. In fact, Westmoreland, assessing the Tet attacks as a serious defeat for the communists, wanted the additional troops to deliver a knockout blow to the weakened enemy. He had been encouraged to request the troops by the Joint Chiefs of Staff, who saw this as an opportunity finally to mobilize the reserves and reconstitute a strategic reserve for use in contingencies other than Vietnam. The president turned the request over to his new secretary of defense, Clark Clifford, who had replaced a disillusioned McNamara a few weeks before. Clifford soon decided not only that massive reinforcements were ill-advised but that the entire war effort had to be reassessed.

De-escalation, negotiation, and Vietnamization

With the aid of some of the president's other advisers and elder statesmen from the Democratic Party, Clifford succeeded in persuading Johnson that the present number of U.S. troops in Vietnam (about 550,000) should constitute an upper limit and that Johnson should make a dramatic gesture for peace. In a nationally televised speech on March 31, Johnson announced that he was "taking the first step to de-escalate the conflict" by halting the bombing of North Vietnam (except in the areas near the DMZ) and that the United States was prepared to send representatives to any forum to seek a negotiated end to the war. He followed this surprising declaration with news that he did not intend to seek reelection that year.

Three days later Hanoi announced that it was prepared to talk to the Americans. Discussions began in Paris on May 13 but led nowhere. Hanoi insisted that, before serious negotiations could begin, the United States would have to halt its bombing of the rest of Vietnam. Meanwhile, fighting continued at a high intensity. The communist high command determined to follow the Tet attacks with two more waves in May and August. At the same time, Westmoreland ordered his commanders to "keep maximum pressure" on the communist forces in the South, which he believed had been seriously weakened by their losses at Tet. The result was the fiercest fighting of the war. In the eight weeks following Johnson's speech, 3,700 Americans were killed in Vietnam and 18,000 wounded. The communists were reported by Westmoreland's headquarters as having lost about 43,000 killed. The ARVN's losses were not recorded, but they were usually twice that of the Americans.

In October the Soviets secretly informed Washington that the North Vietnamese would be willing to halt their attacks across the DMZ and begin serious negotiation with the United States and South Vietnam if the United States halted all bombing of the North. Assured by his military advisers that such a halt would not adversely affect the military situation, Johnson announced the cessation of bombing on the last day of October. The bombing halt achieved no breakthrough but rather brought on a period of prolonged bickering between the United States and its South Vietnamese ally about the terms and procedures to govern the talks. By the time South Vietnam joined the talks, Richard M. Nixon had been elected president.

Nixon and his close adviser on foreign affairs, Henry A. Kissinger, recognized that the United States could not win a military victory in Vietnam but insisted that the war could be ended only by an "honourable" settlement that would afford South Vietnam a reasonable chance of sur-

Paris peace talks start

vival. Nixon planned to achieve this through bringing pressure to bear from the Soviets and China, both of whom were eager to improve their relations with the United States, and through the threat of massive force against North Vietnam. To signal to Hanoi that he could still inflict punishment by air, the president decided to act on the proposal of General Creighton Abrams, who had succeeded Westmoreland in July 1969, that the United States bomb the secret communist base areas in Cambodia near the Vietnamese border.

When the communists launched another wave of attacks in South Vietnam in early 1969, Nixon secretly ordered the bombing to proceed. Cambodian premier Norodom Sihanouk, tired of his uninvited Vietnamese guests, had confidentially approved the attacks, and Hanoi was in no position to complain without revealing its own violation of Cambodia's neutrality. Although elaborate measures had been taken in Washington and Saigon to ensure that the air attacks be kept completely secret, the story broke in the *New York Times* in May. Infuriated by this breach of security, Nixon began a series of measures to plug "leaks" of information; these became part of a broader system of illegal surveillance and burglary that eventually led to the Watergate scandal of 1972.

In view of the surprisingly good performance of the South Vietnamese army at Tet, and responding to growing pressure in the United States to begin a withdrawal of U.S. troops, the Nixon administration decided to accelerate a program to provide South Vietnam with the high-quality weapons and training that would enable them gradually to take over sole responsibility for fighting the ground war— a program labeled Vietnamization. In June 1969 Nixon announced the withdrawal of 25,000 U.S. troops from Vietnam. In September he announced further troop withdrawals, and by March 1970 he was announcing the phased withdrawal of 150,000 troops over the next year. Abrams protested that the still inexperienced and incompletely trained ARVN could hardly take over the job at such a rapid pace, but the withdrawals were enormously popular at home, and the White House soon found them politically indispensable.

Though popular at home, the withdrawals lowered the **Low** morale of the troops remaining in Vietnam by underlining **morale** the apparent pointlessness of the war. By 1970 signs of se-**of U.S.** rious problems in morale and leadership seemed to be **troops** everywhere. These signs included increased drug abuse, more frequent and serious racial incidents, and even "fraggings," the murder or deliberate maiming of commissioned and noncommissioned officers by their own troops with fragmentation weapons such as hand grenades. News of the My Lai Massacre, a mass murder by U.S. soldiers of several hundred civilians in Quang Ngai province in 1968, became public at the end of 1969, further undermining convictions about the righteousness of the U.S. military effort in Vietnam. From 1965 to 1973, more than 30,000 U.S. military personnel either in Vietnam or in service related to Vietnam received dishonourable discharges for desertion (though only a small number of desertions actually took place on the battlefield). Another 10,000 deserters were still at large when the United States withdrew from the war in 1973; most of these took advantage of clemency programs offered under President Gerald R. Ford in 1974 and President Jimmy Carter in 1977. Also during the period 1965–73, about half a million men became "draft dodgers," illegally evading conscription into the armed forces or simply refusing to respond to their draft notices. More than 200,000 men were charged with draft evasion and more than 8,000 convicted. Of those convicted, most were either offered clemency by Ford or pardoned by Carter.

The United States negotiates a withdrawal

While Vietnamization and troop withdrawals proceeded in Vietnam, the negotiations in Paris remained deadlocked. Kissinger secretly opened separate talks with high-level Vietnamese diplomats, but the two sides remained far apart. The Americans proposed a mutual withdrawal of both U.S. and North Vietnamese forces. Hanoi insisted on an unconditional U.S. withdrawal and on the replacement

of the U.S.-backed regime of Nguyen Van Thieu by a neutral coalition government. Nixon considered using renewed bombing and a blockade of the North to coerce the communist leadership, but his military and intelligence experts advised him that such actions would not be likely to have a decisive effect, and his political advisers worried about the impact of such actions on an American public eager to see continued de-escalation of the war.

Nixon consequently refrained from striking North Viet-**The** nam, but he could not resist the opportunity to intervene **Cambo-** in Cambodia, where a pro-Western government under **dian** General Lon Nol had overthrown Sihanouk's neutralist **incursion** regime in March 1970. Since that time, the new regime had attempted to force the communists out of their border sanctuaries. The North Vietnamese easily fended off the attacks of the Cambodian army and began to arm and support the Cambodian communist movement, known as the Khmer Rouge. Eager to support Lon Nol and destroy the sanctuaries, Nixon authorized a large sweep into the border areas by a U.S. and South Vietnamese force of 20,000 men. The allies captured enormous quantities of supplies and equipment but failed to trap any large enemy forces. In the United States, news of the Cambodian incursion triggered widespread protest and demonstrations. These became even more intense after National Guard troops opened fire on a crowd of protesters at Kent State University in Ohio, killing four students and wounding several others, on May 4. At hundreds of campuses, students "went on strike." Congress, meanwhile, repealed the Gulf of Tonkin Resolution.

By the summer of 1970 the White House was left with little more than Vietnamization and troop withdrawals as a way to end the war. Vietnamization appeared to be proceeding smoothly, and American counterinsurgency experts had moved swiftly after Tet to help the South Vietnamese government to develop programs to root out the Viet Cong's underground government and establish control of the countryside. The Viet Cong, seriously weakened by losses in the 1968–69 offensives, now found themselves on the defensive in many areas. However, the limits of Vietnamization were soon demonstrated, when in March 1971 a large ARVN attack into Laos, code-named Lam Son 719 and designed to interdict the Ho Chi Minh Trail, ended in heavy casualties and a disorderly retreat.

In the United States, large-scale demonstrations were now less common, but disillusionment with the war was more widespread than ever. One poll claimed that 71 percent of Americans believed the United States had "made a mistake" in sending troops to Vietnam and that 58 percent found the war "immoral." Discontent was particularly directed toward the selective service system, which had long been seen as unfairly conscripting young men from racial minorities and poor backgrounds while allowing more privileged men to defer conscription by enrolling in higher education. College deferments were limited in 1971, but by that time the military was calling up fewer conscripts each year. Nixon ended all draft calls in 1972, and in 1973 the draft was abolished in favour of an all-volunteer military.

Encouraged by their success in Laos, the Hanoi leadership **North** launched an all-out invasion of the South on March 30, **Vietnam's** 1972, spearheaded by tanks and supported by artillery. **Easter** South Vietnamese forces at first suffered staggering defeats, **offensive** but Nixon, in an operation code-named Linebacker, unleashed U.S. air power against the North, mined Haiphong Harbour (the principal entry point for Soviet seaborne supplies), and ordered hundreds of U.S. aircraft into action against the invasion forces and their supply lines. By mid-June the communists' Easter Offensive had ground to a halt.

With the failure of their offensive, Hanoi leaders were finally ready to compromise. The United States had indicated as early as 1971 that it would not insist on the withdrawal of North Vietnamese forces from the South. Now Hanoi signaled in return that it would not insist on replacing Thieu with a coalition government. On the basis of these two concessions, Kissinger and North Vietnamese emissary Le Duc Tho secretly hammered out a complicated peace accord in October 1972. The Saigon government, however, balked at a peace agreement negotiated without

its participation or consent and demanded important changes in the treaty. In November (following Nixon's re-election), Kissinger returned to Paris with some 69 suggested changes to the agreement designed to satisfy Thieu. The North Vietnamese responded with anger, then with proposed changes of their own. Nixon, exasperated with what he saw as the North's intransigence and also anxious to persuade Thieu to cooperate, ordered B-52 bombers again to attack Hanoi. This so-called Christmas bombing was the most intense bombing campaign of the war. After eight days, the North Vietnamese agreed to return to Paris to sign an agreement essentially the same as that agreed upon in October. Thieu, reassured by a massive influx of U.S. military aid and by a combination of promises and threats from Nixon, reluctantly agreed to go along.

Peace agreement signed

On January 27, 1973, the Agreement on Ending the War and Restoring Peace in Viet-Nam was signed by representatives of the South Vietnamese communist forces, North Vietnam, South Vietnam, and the United States. A cease-fire would go into effect the following morning throughout North and South Vietnam, and within 60 days all U.S. forces would be withdrawn, all U.S. bases dismantled, and all prisoners of war released. An international force would keep the peace, the South Vietnamese would have the right to determine their own future, and North Vietnamese troops could remain in the South but would not be reinforced. The 17th parallel would remain the dividing line until the country could be reunited by "peaceful means."

The fall of South Vietnam

On March 29, 1973, the last U.S. military unit left Vietnam. By that time the communists and South Vietnamese were already engaged in what journalists labeled the "postwar war." Both sides alleged, more or less accurately, that the other side was continuously violating the terms of the peace agreements. The United States maintained its program of extensive military aid to Saigon, but the president's ability to influence events in Vietnam was being sharply curtailed. As Nixon's personal standing crumbled under the weight of Watergate revelations, Congress moved to block any possibility of further military action in Vietnam. In the summer of 1973 Congress passed a measure prohibiting any U.S. military operations in or over Indochina after August 15.

The following year saw a discernible pattern of hostilities: lower levels of combat and casualties, but unimpeded warfare along the never-defined zones of control of the South Vietnamese government and the communists. Hundreds of Vietnamese continued to lose their lives each day after the fighting was supposed to have stopped. By the summer of 1974 Nixon had resigned in disgrace, Congress had cut military and economic aid to Vietnam by 30 percent, and the Lon Nol regime in Cambodia appeared close to defeat. Thieu's government, corrupt and inefficient as ever, now faced difficulties with inflation, unemployment, apathy, and an enormous desertion rate in the army. After an easy

success at Phuoc Long, northeast of Saigon, in December 1974–January 1975, the Hanoi leaders believed that victory was near.

The North's final offensive

In early March the North Vietnamese launched the first phase of what was expected to be a two-year offensive to secure South Vietnam. As it happened, the South's government and army collapsed in less than two months. Thousands of ARVN troops retreated in disorder, first from the central highlands and then from Hue and Da Nang. Gerald R. Ford, who had succeeded Nixon as U.S. president, pleaded in vain with Congress for additional military aid that might at least raise Saigon's morale. But members of Congress, like most of their constituents, were ready to wash their hands of a long and futile war. On April 21 Thieu resigned and flew to Taiwan. On April 30 what remained of the South Vietnamese government surrendered unconditionally, and NVA tank columns occupied Saigon without a struggle. The remaining Americans escaped in a series of frantic air- and sealifts with Vietnamese friends and coworkers. A military government was instituted, and on July 2, 1976, the country was officially united as the Socialist Republic of Vietnam with its capital in Hanoi. Saigon was renamed Ho Chi Minh City. The 30-year struggle for control over Vietnam was over.

Virgil

Virgil was regarded by the Romans as their greatest poet, an estimation that subsequent generations have upheld; his fame rests chiefly upon his national epic poem, the *Aeneid*, which tells the story of Rome's legendary founder and proclaims the Roman mission to civilize the world under divine guidance. His reputation as a poet endures not only for the music and diction of his verse and for his skill in constructing an intricate work on the grand scale but because he embodied in his poetry aspects of experience and behaviour of permanent significance.

Publius Vergilius Maro (the spelling Virgil has become traditional in English, although the form Vergil also is current) was born of peasant stock at Andes, near Mantua, in Italy on October 15, 70 BC. His love of the Italian countryside and of the people who cultivated it colours all his poetry. He was educated at Cremona, at Milan, and finally at Rome, acquiring a thorough knowledge of Greek and Roman authors, especially of the poets, and receiving a detailed training in rhetoric and philosophy. It is known that one of his teachers was the Epicurean Siro, and the Epicurean philosophy is substantially reflected in his early poetry but gradually gives way to attitudes more akin to Stoicism.

Political background.   During Virgil's youth, as the Roman Republic neared its end, the political and military situation in Italy was confused and often calamitous. The civil war between Marius and Sulla had been succeeded by conflict between Pompey and Julius Caesar for supreme power. When Virgil was 20, Caesar with his armies swooped south from Gaul, crossed the Rubicon, and began the series of civil wars that were not to end until Augustus' victory at Actium in 31 BC. Hatred and fear of civil war is powerfully expressed by both Virgil and his contemporary Horace. The key to a proper understanding of the Augustan Age and its poets lies, indeed, in a proper understanding of the turmoil that had preceded the Augustan peace.

Personal
life

Virgil's life was devoted entirely to his poetry and to studies connected with it; his health was never robust, and he played no part in military or political life. It is said that he spoke once in the lawcourts without distinction and that his shy and retiring nature caused him to give up any ideas he might have had of taking part in the world of affairs. He never married, and the first half of his life was that of a scholar and near recluse. But, as his poetry won him fame, he gradually won the friendship of many important men in the Roman world. Gradually, also, he became a Roman as well as a provincial. (The area in which he had spent his youth, the area around the Po River known as the province of Cisalpine Gaul, was not finally incorporated into Italy until 42 BC. Thus Virgil came, as it were, to Rome from the outside. The enthusiasm of a provincial for Rome is seen in the first eclogue, one of his earliest poems, in which the shepherd Tityrus tells of his recent visit to the capital and his amazement at its splendours.)

Literary career.   Some of Virgil's earliest poetry may have survived in a collection of poems attributed to him and known as the *Appendix Vergiliana,* but it is unlikely that many of these are genuine. His earliest certain work is the *Eclogues,* a collection of 10 pastoral poems composed between 42 and 37 BC. Some of them are escapist, literary excursions to the idyllic pastoral world of Arcadia based on the Greek poet Theocritus (fl. c. 280 BC) but more unreal and stylized. They convey in liquid song the idealized situations of an imaginary world in which shepherds sing in the sunshine of their simple joys and mute their sorrows (whether for unhappy love or untimely death) in a formalized pathos. But some bring the pastoral mode into touch with the real world, either directly or by means

of allegory, and thus gave a new direction to the genre. The fifth eclogue, on the death of Daphnis, king of the shepherds, clearly has some relationship with the recent death of Julius Caesar; the 10th brings Gallus, a fellow poet who also held high office as a statesman, into the pastoral world; the first and ninth are lamentations over the expulsion of shepherds from their farms. (It was widely believed in antiquity that these poems expressed allegorically Virgil's own loss of his family farm when the veteran soldiers of Antony and Octavian—later the emperor Augustus—were resettled after the Battle of Philippi in 42 BC. It was thought that he subsequently recovered his property through the intervention of his powerful friends. However that may be, it is certain that the poems are based on Virgil's own experience, whether in connection with his own farm or with those of his friends; and they express, with a poignant pathos that has come to be regarded as specially Virgilian, the sorrow of the dispossessed.)

But one eclogue in particular stands out as having relevance to the contemporary situation, and this is the fourth (sometimes called the Messianic, because it was later regarded as prophetic of Christianity). It is an elevated poem, prophesying in sonorous and mystic terms the birth of a child who will bring back the Golden Age, banish sin, and restore peace. It was clearly written at a time when the clouds of civil war seemed to be lifting; it can be dated firmly to 41–40 BC, and it seems most likely that Virgil refers to an expected child of the triumvir Antony and his wife Octavia, sister of Octavian. But, though a specific occasion may be allocated to the poem, it goes beyond the particular and, in symbolic terms, presents a vision of world harmony, which was, to some extent, destined to be realized under Augustus.

One of the most disastrous effects of the civil wars—and one of which Virgil, as a countryman, would be most intensely aware—was the depopulation of rural Italy. The farmers had been obliged to go to the war, and their farms fell into neglect and ruin as a result. The *Georgics,* composed between 37 and 30 BC (the final period of the civil wars), is a superb plea for the restoration of the traditional agricultural life of Italy. In form it is didactic, but, as Seneca later said, it was written "not to instruct farmers but to delight readers." The practical instruction (about plowing, growing trees, tending cattle, and keeping bees) is presented with vivid insight into nature, and it is interspersed with highly wrought poetical digressions on such topics as the beauty of the Italian countryside (Book

II. line 136 ff.) and the joy of the farmer when all is gathered in (II.458 ff.).

The *Georgics* is dedicated (at the beginning of each book) to Maecenas, one of the chief of Augustus' ministers, who was also the leading patron of the arts. By this time Virgil was a member of what might be called the court circle, and his desire to see his beloved Italy restored to its former glories coincided with the national requirement of resettling the land and diminishing the pressure on the cities. It would be wrong to think of Virgil as writing political propaganda; but equally it would be wrong to regard his poetry as unconnected with the major currents of political and social needs of the time. Virgil was personally committed to the same ideals as the government.

In the year 31 BC, when Virgil was 38, Augustus (still known as Octavian) won the final battle of the civil wars at Actium against the forces of Antony and Cleopatra and from that time dates the Augustan Age. Virgil, like many of his contemporaries, felt a great sense of relief that the senseless civil strife was at last over and was deeply grateful to the man who had made it possible. Augustus was anxious to preserve the traditions of the republic and its constitutional forms, but he was in fact sole ruler of the Roman world. He used his power to establish a period of peace and stability and endeavoured to reawaken in the Romans a sense of national pride and a new enthusiasm for their ancestral religion and their traditional moral values, those of bravery, parsimony, duty, responsibility, and family devotion. Virgil, too, as a countryman at heart, felt a deep attachment to the simple virtues and religious traditions of the Italian people. All his life he had been preparing himself to write an epic poem (regarded then as the highest form of poetic achievement), and he now set out to embody his ideal Rome in the *Aeneid,* the story of the foundation of the first settlement in Italy, from which Rome was to spring, by an exiled Trojan prince after the destruction of Troy by the Greeks in the 12th century BC. The theme he chose gave him two great advantages: one was that its date and subject were very close to those of Homer's *Iliad* and *Odyssey,* so that he could remodel episodes and characters from his great Greek predecessor; and the other was that it could be brought into relationship with his contemporary Augustan world by presenting Aeneas as the prototype of the Roman way of life (the last of the Trojans and the first of the Romans). Moreover, by the use of prophecies and visions and devices such as the description of the pictures on Aeneas' shield or of the origins of contemporary customs and institutions, it could foreshadow the real events of Roman history. The poem, then, operates on a double time scale; it is heroic and yet Augustan.

The enthusiasm that Virgil felt for the reborn Rome promised by Augustus' regime is often reflected in the poem. The sonorous and awe-inspiring prophecy by Jupiter (I.257 ff.), giving a picture of Rome's divinely inspired destiny, has a moving patriotic impact: "To these I set no bounds in space or time—I have given them rule without end" (278–279); and again, under Augustus, "Then shall the harsh generations be softened, and wars shall be laid aside" (291). The speech ends with a memorable image depicting the personified figure of Frenzy in chains, gnashing its bloodstained teeth in vain. At the end of the sixth book, Aeneas visits the underworld, and there pass before his eyes the figures of heroes from Roman history, waiting to be born. The ghost of his father (Anchises) describes them to him and ends by defining the Roman mission as one concerned with government and civilization (compared with the Greek achievement in art and literature and theoretical science). "Rule the people with your sway, spare the conquered, and war down the proud": this is the vision of Rome's destiny that the emperor Augustus and the poet Virgil had before them—that Rome was divinely appointed first to conquer the world in war and then to spread civilization and the rule of law among the peoples. As Horace told the Romans in one of his odes, "Because you are servants of the gods, you are masters on earth."

The vision of Rome that the *Aeneid* expresses is a noble one, but the real greatness of the poem is due to Virgil's awareness of the private, as well as the public, aspects

of human life. The *Aeneid* is no panegyric; it sets the achievements and aspirations of the giant organization of Roman governmental rule in tension with the frustrated hopes and sufferings of individuals. The most memorable figure in the poem—and, it has been said, the only character to be created by a Roman poet that has passed into world literature—is Dido, Queen of Carthage, opponent of the Roman way of life. In a mere panegyric of Rome, she could have been presented in such a way that Aeneas' rejection of her would have been a victory to applaud; but, in fact, in the fourth book she wins so much sympathy that the reader wonders whether Rome should be bought at this price. Again, Turnus, who opposes Aeneas when he lands in Italy, resists the invader who has come to steal his bride. It is clear that Turnus is a less civilized character than Aeneas—but in his defeat Virgil allows him to win much sympathy. These are two examples of the tension against Roman optimism; in many other ways, too, Virgil throughout the poem explores the problems of suffering and the pathos of the human situation. Yet in the end, Aeneas endures and continues to his goal; his devotion to duty (*pietas*) prevails, and the Roman reader would feel that this should be. "So great a task it was to found the Roman nation" (I.33).

The *Aeneid* occupied Virgil for 11 years and, at his death, had not yet received its final revision. In 19 BC, planning to spend a further three years on his poem, he set out for Greece—doubtless to obtain local colour for the revision of those parts of the *Aeneid* set in Greek waters. On the voyage he caught a fever and returned to Italy but died soon after arrival at Brundisium. Whether the *Aeneid* would have undergone major changes cannot be guessed; the story goes that Virgil's dying wish was for his poem to be burned, but that this request was countermanded by the order of Augustus. As it stands, the poem is a major monument both to the national achievements and ideals of the Augustan Age of Rome and to the sensitive and lonely voice of the poet who knew the "tears in things" as well as the glory.

Influence and reputation. Virgil's poetry immediately became famous in Rome and was admired by the Romans for two main reasons—first, because he was regarded as their own national poet, spokesman of their ideals and achievements; second, because he seemed to have reached the ultimate of perfection in his art (his structure, diction, metre). For the latter reason, his poems were used as school textbooks, and the 1st-century Roman critic and teacher Quintilian recommended that the educational curriculum should be based on Virgil's works. A few years after his death, Virgil was being imitated and echoed by the younger poet Ovid, and this process continued throughout the Silver Age. The study of Virgil in the schools has lasted as long as Latin has been studied. By the 4th century a new reason for admiration was gaining ground: the store of wisdom and knowledge discovered by scholars in Virgil's poems—for which he was saluted not only as a poet but as a repository of information. This aspect figures largely in the writings of the writer and philosopher Macrobius (fl. *c.* AD 400), those of Virgil's commentator Servius of the late 4th and early 5th century, and those of many later writers. Allegorical interpretations began to gain ground and, under Christian influence, became especially widespread throughout the Middle Ages. The two main bases for Christian allegorization were the fourth eclogue, believed to be a prophecy of the birth of Christ, and the near-Christian values expressed in the *Aeneid,* especially in its hero, a man devoted to his divine mission. The culmination of this view is Virgil's place of honour in Dante's *Divine Comedy* as the poet's guide through Hell and Purgatory up to the very gates of Paradise.

Virgil's influence on English literature has been enormous. He was Edmund Spenser's constant inspiration for the fanciful beauty of *The Faerie Queene.* The *Aeneid* was the model for John Milton's *Paradise Lost* not only in epic structure and machinery but also in style and diction. In the English Augustan age, John Dryden and countless others held that Virgil's poetry had reached the ultimate perfection of form and ethical content. There was some reaction against him in the Romantic period, but

the Victorians, such as Matthew Arnold and Alfred, Lord Tennyson, rediscovered in full measure that sensitivity and pathos that the Romantics had complained that Virgil lacked.

MAJOR WORKS

Eclogae (42–37 BC; *Eclogues*), comprising 10 poems also known as the *Bucolica*; *Georgica* (37–30 BC; *Georgics*), comprising 4 books of poems on farming and rural life in Italy; and *Aeneis* (30–19 BC; *Aeneid*), an epic poem in 12 books.

Many English translations of Virgil's works have been made, including verse translations by Gavin Douglas (1553), John Dryden (1697), C. Day Lewis (1940–63), and Rolfe Humphries (1951). Notable among prose translations are those by J.W. Mackail (2nd ed. rev., 1908–14), H.R. Fairclough ("Loeb Series," 1934–35); and W.F. Jackson Knight (1956). There is a French translation of all the works in the "Budé Series" (1926–56).

BIBLIOGRAPHY. Detailed bibliographical information about Virgil may be found in the lists in *L'Année philologique* (annual). In English there are bibliographical surveys by G.E. DUCKWORTH, *Classical World*, vol. 51 (1957–58) and vol. 57 (1963–64), reissued as *Recent Work on Vergil*, 2 vol. (1964); the summaries in *Vergilius* (annual), the journal of the Vergilian Society (U.S.); the reviews of important modern works in the *Proceedings of the Virgil Society* (annual), the journal of the Virgil Society (U.K.); and the survey by R.D. WILLIAMS, *Virgil* (1967).

Texts: The best texts of Virgil's work (including discussion of the manuscripts) are those of R.A.B. MYNORS, "Oxford Classical Texts" (1969), replacing Hirtzel's 1900 edition; R. SABBADINI (1930; reprinted with minor alterations by L. CASTIGLIONI, 1945–52); E. DE SAINT-DENIS (*Eclogues,* 1942; *Georgics,* 1956); and GOELZER-DURAND-BELLESSORT, *Aeneid,* 2 vol. (1925–36), in the "Budé Series."

Commentaries: The commentaries by SERVIUS have been edited by GEORG THILO and HERMANN HAGEN, *Servii Grammatici qvi fervntvr in Vergilii carmina commentarii,* 3 vol. (1881–1902); and by EDWARD K. RAND *et al.* (*Aeneid,* books 1 and 2, 1946; books 3 to 5, 1965); JAMES HENRY, *Aeneidea,* 4 vol. (1873–92, reprinted 1972); CONINGTON-NETTLESHIP-HAVERFIELD, 3 vol. (1858–98); THOMAS E. PAGE, *The Aeneid of Virgil* (1894–1900); and R.D. WILLIAMS, *The Aeneid of Virgil,* 2 vol. (1972–73).

Biography and criticism: For such biographical facts as are known about Virgil, see the introduction to JOHN W. MACKAIL, *Aeneid* (1930); and W.F. JACKSON KNIGHT, *Roman Vergil,* rev. ed. (1966, reissued 1971). GILBERT A. HIGHET, *Poets in a Landscape* (1957, reprinted 1979), gives a popular and readable account. The ancient sources are collected in *Vitae Vergilianae Antiquae* (1954, reissued 1966). An excellent critical evaluation of Virgil's *Aeneid* is W.A. CAMPS, *An Introduction to Virgil's Aeneid* (1969). Other important works are T.R. GLOVER, *Virgil,* 7th ed. (1942, reissued 1969); C.M. BOWRA, *From Virgil to Milton* (1945, reissued 1967); BROOKS OTIS, *Virgil: A Study in Civilised Poetry* (1963); KENNETH QUINN, *Virgil's Aeneid: A Critical Description* (1968); D.R. DUDLEY (ed.), *Virgil* (1969); and J. WILLIAM HUNT, *Forms of Glory* (1973), an introductory study of the *Aeneid.* On the *Eclogues,* see HERBERT J. ROSE, *The Eclogues of Vergil* (1942); and WILLIAM BERG, *Early Virgil* (1974). On the *Georgics,* see L.P. WILKINSON, *The Georgics of Virgil* (1969, reissued 1978); MICHAEL C.J. PUTNAM, *Virgil's Poem of the Earth* (1979); and GARY B. MILES, *Virgil's Georgics: A New Interpretation* (1980). On Virgil's influence, see G.A. HIGHET, *The Classical Tradition* (1949, reissued 1967); R.R. BOLGAR, *The Classical Heritage and Its Beneficiaries* (1954, reissued 1973); D. COMPARETTI, *Vergil in the Middle Ages* (1895); J.H. WHITFIELD, "Virgil into Dante"; and R.D. WILLIAMS, "Changing Attitudes to Virgil," chapters 4 and 5 in D.R. DUDLEY (cited above).

Virtual Reality

Virtual reality (VR) encompasses the use of computer modeling and simulation that enables a person to interact with an artificial three-dimensional (3-D) visual or other sensory environment. VR applications immerse the user in a computer-generated environment that simulates reality through the use of interactive devices, which send and receive information and are worn as goggles, headsets, gloves, or body suits. In a typical VR format, a user wearing a helmet with a stereoscopic screen views animated images of a simulated environment. The illusion of "being there" (telepresence) is effected by motion sensors that pick up the user's movements and adjust the view on the screen accordingly, usually in real time (the instant the user's movement takes place). Thus, a user can tour a simulated suite of rooms, experiencing changing viewpoints and perspectives that are convincingly related to his own head turnings and steps. Wearing data gloves equipped with force-feedback devices that provide the sensation of touch, the user can even pick up and manipulate objects that he sees in the virtual environment.

The term *virtual reality* was coined in 1987 by Jaron Lanier, whose research and engineering contributed a number of products to the nascent VR industry. A common thread linking early VR research and technology development in the United States was the role of the federal government, particularly the Department of Defense, the National Science Foundation, and the National Aeronautics and Space Administration (NASA). Projects funded by these agencies and pursued at university-based research laboratories yielded an extensive pool of talented personnel in fields such as computer graphics, simulation, and networked environments and established links between academic, military, and commercial work. The history of this technological development, and the social context in which it took place, is the subject of this article.

This article is divided into the following sections:

EARLY WORK

Artists, performers, and entertainers have always been interested in techniques for creating imaginative worlds, setting narratives in fictional spaces, and deceiving the senses. Numerous precedents for the suspension of disbelief in an artificial world in artistic and entertainment media preceded virtual reality. Illusionary spaces created by paintings or views have been constructed for residences and public spaces since antiquity, culminating in the monumental panoramas of the 18th and 19th centuries. Panoramas blurred the visual boundaries between the two-dimensional images displaying the main scenes and the three-dimensional spaces from which these were viewed, creating an illusion of immersion in the events depicted. This image tradition stimulated the creation of a series of media—from futuristic theatre designs, stereopticons, and 3-D movies to IMAX movie theatres—over the course of the 20th century to achieve similar effects. For example, the Cinerama widescreen film format, originally called Vitarama when invented for the 1939 New York World's Fair by Fred Waller and Ralph Walker, originated in Waller's studies of vision and depth perception. Waller's work led him to focus on the importance of peripheral vision for immersion in an artificial environment, and his goal was to devise a projection technology that could duplicate the entire human field of vision. The Vitarama process used multiple cameras and projectors and an arc-shaped screen to create the illusion of immersion in the space perceived by a viewer. Though Vitarama was not a commercial hit until the mid-1950s (as Cinerama), the Army Air Corps successfully used the system during World War II for anti-aircraft training under the name Waller Flexible Gunnery Trainer—an example of the link between entertainment technology and military simulation that would later advance the development of virtual reality.

Sensory stimulation was a promising method for creating virtual environments before the use of computers. After the release of a promotional film called *This Is Cinerama* (1952), the cinematographer Morton Heilig became fascinated with Cinerama and 3-D movies. Like Waller, he studied human sensory signals and illusions, hoping to realize a "cinema of the future." By late 1960, Heilig had built an individual console with a variety of inputs—stereoscopic images, motion chair, audio, temperature changes, odours, and blown air—that he patented in 1962 as the Sensorama Simulator, designed to "stimulate the senses of an individual to simulate an actual experience realistically." During the work on Sensorama, he also designed the Telesphere Mask, a head-mounted "stereoscopic 3-D TV display" that he patented in 1960. Although Heilig was unsuccessful in his efforts to market Sensorama, in the mid-1960s he extended the idea to a multiviewer theatre concept patented as the Experience Theater and a similar system called Thrillerama for the Walt Disney Company.

The seeds for virtual reality were planted in several computing fields during the 1950s and '60s, especially in 3-D interactive computer graphics and vehicle/flight simulation. Beginning in the late 1940s, Project Whirlwind, funded by the U.S. Navy, and its successor project, the SAGE (Semi-Automated Ground Environment) early-warning radar system, funded by the U.S. Air Force, first utilized cathode-ray tube (CRT) displays and input devices such as light pens (originally called "light guns"). By the time the SAGE system became operational in 1957, Air Force operators were routinely using these devices to display aircraft positions and manipulate related data. **SAGE**

During the 1950s, the popular cultural image of the computer was that of a calculating machine, an automated electronic brain capable of manipulating data at previously unimaginable speeds. The advent of more affordable second-generation (transistor) and third-generation (integrated circuit) computers emancipated the machines from this narrow view, and in doing so it shifted attention to ways in which computing could augment human potential rather than simply substituting for it in specialized domains conducive to number crunching. In 1960 Joseph Licklider, a professor at the Massachusetts Institute of Technology (MIT) specializing in psychoacoustics, posited a "man-computer symbiosis" and applied psychological principles to human-computer interactions and interfaces. He argued that a partnership between computers and the human brain would surpass the capabilities of either alone. As founding director of the new Information Processing Techniques Office (IPTO) of the Defense Advanced Research Projects Agency (DARPA), Licklider was able to fund and encourage projects that aligned with his vision of human-computer interaction while also serving priorities for military systems, such as data visualization and command-and-control systems. **DARPA**

Another pioneer was electrical engineer and computer scientist Ivan Sutherland, who began his work in computer graphics at MIT's Lincoln Laboratory (where Whirlwind and SAGE had been developed). In 1963 Sutherland completed Sketchpad, a system for drawing interactively on a CRT display with a light pen and control board. Sutherland paid careful attention to the structure of data representation, which made his system useful for the interactive

Figure 1: Ivan Sutherland and early head-mounted display, c. 1967.
Courtesy of Ivan Sutherland

manipulation of images. In 1964 he was put in charge of IPTO, and from 1968 to 1976 he led the computer graphics program at the University of Utah, one of DARPA's premier research centres. In 1965 Sutherland outlined the characteristics of what he called the "ultimate display" and speculated on how computer imagery could construct plausible and richly articulated virtual worlds. His notion of such a world began with visual representation and sensory input, but it did not end there; he also called for multiple modes of sensory input. DARPA sponsored work during the 1960s on output and input devices aligned with this vision, such as the Sketchpad III system by Timothy Johnson, which presented 3-D views of objects; Larry Roberts' Lincoln Wand, a system for drawing in three dimensions; and Douglas Engelbart's invention of a new input device, the computer mouse.

Within a few years, Sutherland contributed the technological artifact most often identified with virtual reality, the head-mounted 3-D computer display. In 1967 Bell Helicopter (now part of Textron Inc.) carried out tests in which a helicopter pilot wore a head-mounted display (HMD) that showed video from a servo-controlled infrared camera mounted beneath the helicopter. The camera moved with the pilot's head, both augmenting his night vision and providing a level of immersion sufficient for the pilot to equate his field of vision with the images from the camera. This kind of system would later be called "augmented reality" because it enhanced a human capacity (vision) in the real world. When Sutherland left DARPA for Harvard University in 1966, he began work on a tethered display for computer images. This was an apparatus shaped to fit over the head, with goggles that displayed computer-generated graphical output. Because the display was too heavy to be borne comfortably, it was held in place by a suspension system. Two small CRT displays were mounted in the device, near the wearer's ears, and mirrors reflected the images to his eyes, creating a stereo 3-D visual environment that could be viewed comfortably at a short distance. The HMD also tracked where the wearer was looking so that correct images would be generated for his field of vision. The viewer's immersion in the displayed virtual space was intensified by the visual isolation of the HMD, yet other senses were not isolated to the same degree and the wearer could continue to walk around.

HMD

EDUCATION AND TRAINING

An important area of application for VR systems has always been training for real-life activities. The appeal of simulations is that they can provide training equal or nearly equal to practice with real systems, but at reduced cost and with greater safety. This is particularly the case for military training, and the first significant application of commercial simulators was pilot training during World War II. Flight simulators rely on visual and motion feedback to augment the sensation of flying while seated in a closed mechanical system on the ground. The Link Company, founded by former piano maker Edwin Link, began to construct the first prototype Link Trainers during the late 1920s, eventually settling on the "blue box" design acquired by the Army Air Corps in 1934. The first systems used motion feedback to increase familiarity with flight controls. Pilots trained by sitting in a simulated cockpit, which could be moved hydraulically in response to their actions. Later versions added a "cyclorama" scene painted on a wall outside the simulator to provide limited visual feedback. Not until the Celestial Navigation Trainer, commissioned by the British government in World War II, were projected film strips used in Link Trainers—still, these systems could only project what had been filmed along a correct flight or landing path, not generate new imagery based on a trainee's actions. By the 1960s, flight trainers were using film and closed-circuit television to enhance the visual experience of flying. The images could be distorted to generate flight paths that diverted slightly from what had been filmed; sometimes multiple cameras were used to provide different perspectives, or movable cameras were mounted over scale models to depict airports for simulated landings.

Link Trainers

Inspired by the controls in the Link flight trainer, Sutherland suggested that such displays include multiple sensory outputs, force-feedback joysticks, muscle sensors, and eye trackers; a user would be fully immersed in the displayed environment and fly through "concepts which never before had any visual representation." In 1968 he moved to the University of Utah, where he and his colleague David Evans founded Evans & Sutherland Computer Corporation. The new company initially focused on the development of graphics applications, such as scene generators for flight simulator systems. These systems could render scenes at roughly 20 frames per second in the early 1970s, about the minimum frame rate for effective flight training. General Electric Company constructed the first flight simulators with built-in, real-time computer image generation, first for the Apollo program in the 1960s, then for the U.S. Navy in 1972. By the mid-1970s, these systems were capable of generating simple 3-D models with a few hundred polygon faces; they utilized raster graphics (collections of dots) and could model solid objects with textures to enhance the sense of realism. By the late 1970s, military flight simulators were also incorporating head-mounted displays, such as McDonnell Douglas Corporation's VITAL helmet,

TRH Pictures

Figure 2: Link Trainer, 1940s.

primarily because they required much less space than a projected display. A sophisticated head tracker in the HMD followed a pilot's eye movements to match computer-generated images (CGI) with his view and handling of the flight controls.

Advances in flight simulators, human-computer interfaces, and augmented reality systems pointed to the possibility of immersive, real-time control systems, not only for research or training but also for improved performance. Since the 1960s, electrical engineer Thomas Furness had been working on visual displays and instrumentation in cockpits for the U.S. Air Force. By the late 1970s, he had begun development of virtual interfaces for flight control, and in 1982 he demonstrated the Visually Coupled Airborne Systems Simulator—better known as the Darth Vader helmet, for the armoured archvillain of the popular movie *Star Wars*. From 1986 to 1989, Furness directed the Air Force's Super Cockpit program. The essential idea of this project was that the capacity of human pilots to handle spatial information depended on these data being "portrayed in a way that takes advantage of the human's natural perceptual mechanisms." Applying the HMD to this goal, Furness designed a system that projected information such as computer-generated 3-D maps, forward-looking infrared and radar, and avionics data into an immersive, 3-D virtual space that the pilot could view and hear in real time. The helmet's tracking system, voice-actuated controls, and sensors enabled the pilot to control the aircraft with gestures, utterances, and eye movements, translating immersion in a data-filled virtual space into control modalities. The more natural perceptual interface also reduced the complexity and number of controls in the cockpit. The Super Cockpit thus realized Licklider's vision of man-machine symbiosis by creating a virtual environment in which pilots flew through data. Beginning in 1987, British Aerospace (now part of BAE Systems) also used the HMD as the basis for a similar training simulator, known as the Virtual Cockpit, that incorporated head, hand, and eye tracking, as well as speech recognition.

Sutherland and Furness brought the notion of simulator technology from real-world imagery to virtual worlds that represented abstract models and data. In these systems, visual verisimilitude was less important than immersion and feedback that engaged all the senses in a meaningful way. This approach had important implications for medical and Project scientific research. Project GROPE, started in 1967 at the GROPE University of North Carolina by Frederick Brooks, was particularly noteworthy for the advancements it made possible in the study of molecular biology. Brooks sought to enhance perception and comprehension of the interaction of a drug molecule with its receptor site on a protein by creating a window into the virtual world of molecular docking forces. He combined wire-frame imagery to represent molecules and physical forces with "haptic" (tactile) feedback mediated through special hand-grip devices to arrange the virtual molecules into a minimum binding energy configuration. Scientists using this system felt their way around the represented forces like flight trainees learning the instruments in a Link cockpit, "grasping" the physical situations depicted in the virtual world and hypothesizing new drugs based on their manipulations. During the 1990s, Brooks's laboratory extended the use of virtual reality to radiology and ultrasound imaging.

Virtual reality was extended to surgery through the technology of telepresence, the use of robotic devices controlled remotely through mediated sensory feedback to perform a task. The foundation for virtual surgery was the expansion during the 1970s and '80s of microsurgery and other less invasive forms of surgery. By the late 1980s, microcameras attached to endoscopic devices relayed images that could be viewed by surgeons in diverse locations. In the early 1990s, a DARPA initiative funded research to develop telepresence workstations for surgical procedures. This was Sutherland's "window into a virtual world," with the added dimension of a level of sensory feedback that could match a surgeon's fine motor control and hand-eye coordination. The first telesurgery equipment was developed at SRI International in 1993; the first robotic surgery was performed in 1998 at the Broussais Hospital in Paris.

ENTERTAINMENT

As virtual worlds became more detailed and immersive, people began to spend time in these spaces for entertainment, aesthetic inspiration, and socializing. Research that conceived of virtual places as fantasy spaces, focusing on the activity of the subject rather than replication of some real environment, was particularly conducive to entertainment. Beginning in 1969, Myron Krueger of the University of Wisconsin created a series of projects on the nature of human creativity in virtual environments, which he later called artificial reality. Much of Krueger's work, especially his VIDEOPLACE system, processed interactions VIDEO-between a participant's digitized image and computer-gen-PLACE erated graphical objects. VIDEOPLACE could analyze and process the user's actions in the real world and translate them into interactions with the system's virtual objects in various preprogrammed ways. Different modes of interaction with names like "finger painting" and "digital drawing" suggest the aesthetic dimension of this system. VIDEOPLACE differed in several aspects from training and research simulations. In particular, the system reversed the emphasis from the user perceiving the computer's generated world to the computer perceiving the user's actions and converting these actions into compositions of objects and space within the virtual world. With the emphasis shifted to responsiveness and interaction, Krueger found that fidelity of representation became less important than the interactions between participants and the rapidity of response to images or other forms of sensory input.

The ability to manipulate virtual objects and not just see them is central to the presentation of compelling virtual worlds—hence the iconic significance of the data glove in the emergence of VR in commerce and popular culture. Data gloves relay a user's hand and finger movements to a VR system, which then translates the wearer's gestures into manipulations of virtual objects. The first data glove, developed in 1977 at the University of Illinois for a project funded by the National Endowment for the Arts, was called the Sayre Glove after one of the team members. In 1982 Thomas Zimmerman invented the first optical glove, and in 1983 Gary Grimes at Bell Laboratories constructed the Digital Data Entry Glove, the first glove with sufficient flexibility and tactile and inertial sensors to monitor hand position for a variety of applications, such as providing an alternative to keyboard input for data entry.

Zimmerman's glove would have the greatest impact. He had been thinking for years about constructing an interface device for musicians based on the common practice of playing "air guitar"—in particular, a glove capable of tracking hand and finger movements could be used to control instruments such as electronic synthesizers. He patented an optical flex-sensing device (which used light-conducting fibres) in 1982, one year after Grimes patented his glove-based computer interface device. By then, Zimmerman was working at the Atari Research Center in Sunnyvale, California, along with Scott Fisher, Brenda Laurel, and other VR researchers who would be active during the 1980s and beyond. Jaron Lanier, another researcher at Atari, shared Zimmerman's interest in electronic music. Beginning in 1983, they worked together on improving the design of the data glove, and in 1985 they VPL Data-left Atari to start up VPL Research; its first commercial Glove product was the VPL DataGlove.

By 1985 Fisher had also left Atari to join NASA's Ames Research Center at Moffett Field, California, as founding director of the Virtual Environment Workstation (VIEW) project. The VIEW project put together a package of objectives that summarized previous work on artificial environments, ranging from creation of multisensory and immersive "virtual environment workstations" to telepresence and teleoperation applications. Influenced by a range of prior projects that included Sensorama, flight simulators, and arcade rides, and surprised by the expense of the Air Force's Darth Vader helmets, Fisher's group focused on building low-cost, personal simulation environments. While the objective of NASA was to develop telerobotics for automated space stations in future planetary exploration, the group also considered the workstation's use for entertainment, scientific, and educational purposes. The

VIEW workstation, called the Virtual Visual Environment Display when completed in 1985, established a standard suite of VR technology that included a stereoscopic head-coupled display, head tracker, speech recognition, computer-generated imagery, data glove, and 3-D audio technology.

The VPL DataGlove was brought to market in 1987, and in October of that year it appeared on the cover of *Scientific American*. VPL also spawned a full-body, motion-tracking system called the DataSuit, a head-mounted display called the EyePhone, and a shared VR system for two people called RB2 ("Reality Built for Two"). VPL declared June 7, 1989, "Virtual Reality Day." On that day, both VPL and Autodesk publicly demonstrated the first commercial VR systems. The Autodesk VR CAD (computer-aided design) system was based on VPL's RB2 technology but was scaled down for operation on personal computers. The marketing splash introduced Lanier's new term *virtual reality* as a realization of "cyberspace," a concept introduced in science fiction writer William Gibson's *Neuromancer* in 1984. Lanier, the dreadlocked chief executive officer of VPL, became the public celebrity of the new VR industry, while announcements by Autodesk and VPL let loose a torrent of enthusiasm, speculation, and marketing hype. Soon it seemed that VR was everywhere, from the Mattel/Nintendo PowerGlove (1989) to the HMD in the movie *The Lawnmower Man* (1992), the Nintendo VirtualBoy game system (1995), and the television series *VR5* (1995).

Numerous VR companies were founded in the early 1990s, most of them in Silicon Valley, but by mid-decade most of the energy unleashed by the VPL and Autodesk marketing campaigns had dissipated. The VR configuration that took shape over a span of projects leading from Sutherland to Lanier—HMD, data gloves, multimodal sensory input, and so forth—failed to have a broad appeal as quickly as the enthusiasts had predicted. Instead, the most visible and successfully marketed products were "location-based entertainment" systems rather than personal VR systems. These VR arcades and simulators, designed by teams from the game, movie, simulation, and theme park industries, combined the attributes of video games, amusement park rides, and highly immersive storytelling. Perhaps the most important of the early projects was Disneyland's Star Tours, an immersive flight simulator ride based on the *Star Wars* movie series and designed in collaboration with producer George Lucas' Industrial Light

and Magic. Disney had long built themed rides utilizing advanced technology, such as animatronic characters—notably in Pirates of the Caribbean, an attraction originally installed at Disneyland in 1967. Star Tours utilized simulated motion and special-effects technology, mixing techniques learned from Hollywood films and military flight simulators with strong story lines and architectural elements that shaped the viewers' experience from the moment they entered the waiting line for the attraction. After the opening of Star Tours in 1987, Walt Disney Imagineering embarked on a series of projects to apply interactive technology and immersive environments to ride systems, including 3-D motion-picture photography used in *Honey, I Shrunk the Audience* (1995), the DisneyQuest "indoor interactive theme park" (1998), and the multiplayer-gaming virtual world, *Toontown Online* (2001).

In 1990 Virtual World Entertainment (VWE) opened the first *BattleTech* emporium in Chicago. Modeled loosely on the U.S. military's SIMNET system of networked training simulators, *BattleTech* centres put players in individual "pods," essentially cockpits that served as immersive, interactive consoles for both narrative and competitive game experiences. All the vehicles represented in the game were controlled by other players, each in his own pod and linked to a high-speed network set up for a simultaneous multiplayer experience. The player's immersion in the virtual world of the competition resulted from a combination of elements, including a carefully constructed story line, the physical architecture of the arcade space and pod, and the networked virtual environment. During the 1990s, *BattleTech* centres were constructed in other cities around the world, and the *BattleTech* franchise also expanded to home electronic games, books, toys, and television.

While the Disney and VWE projects were the best-known instances of location-based VR entertainments, other important projects included Iwerks Entertainment's Turbo Tour and Turboride 3-D motion simulator theatres, first installed in San Francisco in 1992; motion-picture producer Steven Spielberg's Gameworks arcades, the first of which opened in 1997 as a joint project of Universal Studios, Sega Corporation, and Dreamworks SKG; many individual VR arcade rides, beginning with Sega Arcade's R360 gyroscope flight simulator, released in 1991; and, finally, Visions of Reality's VR arcades, the spectacular failure of which contributed to the bursting of the investment bubble for VR ventures in the mid-1990s.

LIVING IN VIRTUAL WORLDS

By the beginning of 1993, VPL had closed its doors and pundits were beginning to write of the demise of virtual reality. Despite the collapse of efforts to market VR workstations in the configuration stabilized at VPL and NASA, virtual world, augmented reality, and telepresence technologies were successfully launched throughout the 1990s and into the 21st century as platforms for creative work, research spaces, games, training environments, and social spaces. Military and medical needs also continued to drive these technologies through the 1990s, often in partnership with academic institutions or entertainment companies. With the rise of the Internet, attention shifted to the application of networking technology to these projects, bringing a vital social dimension to virtual worlds. People were learning to live in virtual spaces.

The designers of NASA's Visual Environment Display workstation cited the goal of putting viewers inside an image; this meant figuratively putting users inside a computer by literally putting them inside an assemblage of input and output devices. By the mid-1990s, Mark Weiser at Xerox PARC had begun to articulate a research program that instead sought to introduce computers into the human world. In an article titled "The Computer for the 21st Century," published in *Scientific American* (1991), Weiser introduced the concept of ubiquitous computing. Arguing that "the most profound technologies are those that disappear" by weaving "themselves into the fabric of everyday life until they are indistinguishable from it," he proposed that future computing devices would outnumber people—embedded in real environments, worn on bodies, and communicating with each other through personal vir-

Margin notes: DataSuit · Star Tours · BattleTech · Ubiquitous computing

tual agents. These computers would be so natural that human users would not need to think about them, thus inaugurating an era of "calm technology." If Weiser's ubiquitous computing is thought of as complementary rather than opposed to VR, one can see traces of his ideas in a variety of post-VR systems.

A large group of systems involved projecting images in physical spaces more natural than a VR workstation. In 1992 researchers from the University of Illinois at Chicago presented the first Cave Automatic Virtual Environment CAVE (CAVE). CAVE was a VR theatre, a cube with 10-foot-square walls onto which images were projected so that users were surrounded by sights and sounds. One or more people wearing lightweight stereoscopic glasses walked freely in the room, their head and eye movements tracked to adjust the imagery, and they interacted with 3-D virtual objects by manipulating a wand-like device with three buttons. The natural field of vision of anyone in a CAVE was filled with imagery, adding to the sense of immersion, but the environment allowed greater freedom of movement than VR workstations, and several people could share the space and discuss what they saw.

Other examples of more natural virtual spaces included the Virtual Reality Responsive Workbench, developed in the mid-1990s by the U.S. Naval Research Laboratory and collaborating institutions. This system projected stereoscopic 3-D images onto a horizontal tabletop display viewed through shutter glasses. With data gloves and a stylus, researchers could interact with the displayed image, which might represent data or a human body for scientific or medical applications. The shift to projected VR environments in artistic and scientific work put aside the bulky VR helmets of the 1980s in favour of lightweight eyeglasses, wearable sensors, and greater freedom of movement.

Another important application of VR during the 1990s was social interaction in virtual worlds. Military simulation and multiplayer networked gaming led the way. Indeed, the first concerted efforts by the military to tap the potential of computer-based war gaming and simulation had taken place in the mid-1970s. During the 1980s, the increasing expense of traditional (live) exercises focused attention on the resource efficiency of computer-based simulations. The most important networked virtual environment to come out of this era was the DARPA-SIMNET funded SIMulator NETworking (SIMNET) project, begun in 1983 under the direction of Jack Thorpe. SIM-NET was a network of simulators (armoured vehicles and helicopters, initially) that were linked together for collective training. It differed from previous stand-alone simulator systems in two important respects. First, because the training objectives included command and control, the design focused on effect rather than physical fidelity; psychological or operational aspects of battle, for example, only required selective verisimilitude in cabinet design or computer-generated imagery. Second, by linking together simulators, SIMNET created a network not just of physical connections but also of social interactions among players. Aspects of the virtual world emerged from social interactions among participants that had not been explicitly programmed into the computer-generated environment. These interactions among participants were usually of greater relevance to collective training than anything an individual simulator station could provide. In gaming terms, player-versus-player interactions became as important as player-versus-environment interactions.

SIMNET was followed by a series of increasingly sophisticated networked simulations and projects. Important moments included *The Battle of 73 Easting* (1992), a fully 3-D simulation based on SIMNET of a key armoured battle in the First Persian Gulf War; the approval of a standard protocol for Distributed Interactive Simulation in 1993; and the U.S. Army's Synthetic Theater of War demonstration project (1997), a large-scale distributed simulation of a complete theatre battle capable of involving thousands of participants.

The other important source of populated virtual worlds was computer games. Early games such as *Spacewar!* (1962) and *Adventure* (c. 1975) were played via time-shared computers, then over modems, and eventually on networks. Some were based on multiplayer role-playing in the virtual worlds depicted in the game, such as *Mines of Moria* (c. 1974) from the University of Illinois's Project Plato and the original "multiuser dungeon," or *MUD*, developed by Richard Bartle and Roy Trubshaw at the University of Essex, England, in 1979, which combined *Adventure*-like exploration of virtual spaces with social interaction. MUDs were shared environments that support-MUDs ed social interaction and performance as well as competitive play among a community of players, many of whom stayed with the game for years. Hundreds of themed multiplayer MUDs, MOOs (object-oriented MUDs), and bulletin-board-system games, or BBS games, provided persistent virtual spaces through the 1980s and '90s. By the mid-1990s, advances in networking technology and graphics combined to open the door to graphical MUDs and "massively multiplayer" games, such as *Ultima Online*, *Everquest*, and *Asheron's Call*, set in virtual worlds populated by thousands of players at a time.

Competitive networked games also provided virtual spaces for interaction among players. In 1993 id Software introduced *DOOM*, which defined the game genre known as the first-person shooter and established competitive multiplayer gaming as the leading-edge category of games on personal computers. The programming team, led by John Carmack, took advantage of accelerated 3-D graphics hardware to enable rapid movement through an open virtual space as seen from the perspective of each player. *DOOM*'s fast peer-to-peer networking was perfect for multiplayer gaming, and id's John Romero devised the "death match" as a mode of fast, violent, and competitive gameplay. The U.S. military also adapted the first-person shooter for training purposes, beginning with a modified version of *DOOM*, known as *Marine Doom*, used by the Marine Corps and leading to the adoption of the *Unreal* game engine for the U.S. Army's official game, *America's Army* *America's* (2002), developed by the Modeling, Simulation, and Vir- *Army* tual Environments Institute of the Naval Postgraduate School in Monterey, California. First-person shooters, squad-based tactical games, and real-time strategy games are now routinely developed in parallel military and commercial versions, and these immersive, interactive, real-time training simulations have become a form of mainstream entertainment. Viruses

Virus is a Latin word meaning "slimy liquid" or "poison." The earliest indications of the biological nature of viruses came from studies in 1892 by the Russian scientist Dmitry I. Ivanovsky and in 1898 by the Dutch scientist Martinus W. Beijerinck. Beijerinck first surmised that the virus under study was a new kind of infectious agent, which he designated *contagium vivum fluidum,* meaning that it was a live, reproducing organism that, nevertheless, differed from other organisms. Both of these investigators found that a disease of tobacco plants could be transmitted by an agent, later called tobacco mosaic virus, passing through a minute filter that would not allow the passage of bacteria. This virus and those subsequently isolated would not grow on an artificial medium and were not visible under the light microscope. In independent studies in 1915 by the British investigator Frederick W. Twort and in 1917 by the French-Canadian scientist Félix H. d'Hérelle, lesions in cultures of bacteria were discovered and attributed to an agent called bacteriophage ("eater of bacteria"), now known to be viruses that specifically infect bacteria.

The unique nature of these organisms meant that new methods and alternative models had to be developed to study and classify them. The study of viruses confined exclusively or largely to humans, however, posed the formidable problem of finding a susceptible animal host. In 1933 the British investigators Wilson Smith, Christopher H. Andrewes, and Patrick P. Laidlaw were able to transmit influenza to ferrets, and the influenza virus was subsequently adapted to mice. In 1941 the American scientist George K. Hirst found that influenza virus grown in tissues of the chicken embryo could be detected by its capacity to agglutinate (draw together) red blood cells.

A significant advance was made by the American scientists John Enders, Thomas Weller, and Frederick Robbins, who in 1949 developed the technique of culturing cells on glass surfaces; cells could then be infected with the viruses that cause poliomyelitis (poliovirus) and other diseases. (Until this time the poliovirus could be grown only in the brains of chimpanzees or the spinal cords of monkeys.) Culturing cells on glass surfaces opened the way for the diagnosis of diseases caused by viruses identified by their effects on cells (cytopathogenic effect) and by the presence of antibodies to them in the blood. Cell culture then led to the development and production of vaccines (preparations used to elicit immunity against a disease), such as the poliovirus vaccine.

Scientists were soon able to detect the number of bacterial viruses in a culture vessel by measuring their ability to break apart (lyse) adjoining bacteria, which resulted in a clearing, or "plaque," in an area of bacteria (lawn) overlaid with an inert gelatinous substance, called agar. The American scientist Renato Dulbecco in 1952 applied this technique to measuring the number of animal viruses that could produce plaques in layers of adjoining animal cells overlaid with agar. In the 1940s the development of the electron microscope permitted individual virus particles to be seen for the first time, leading to the classification of viruses and giving insight into their structure.

Advancements that were made in chemistry, physics, and molecular biology since the 1960s have revolutionized the study of viruses. For example, electrophoresis on gel substrates gave a deeper understanding of the protein and nucleic acid composition of viruses. More sophisticated immunologic procedures, including the use of monoclonal antibodies directed to specific antigenic sites on proteins, gave a better insight into the structure and function of viral proteins. The progress made in the physics of crystals that could be studied by X-ray diffraction provided the high resolution required to discover the basic structure of minute viruses. Applications of new knowledge about cell biology and biochemistry helped to determine how viruses use their host cells for synthesizing viral nucleic acids and proteins.

The revolution that took place in the field of molecular biology allowed the genetic information encoded in nucleic acids of viruses—which enables viruses to reproduce, synthesize unique proteins, and alter cellular functions—to be studied. In fact, the chemical and physical simplicity of viruses has made them an incisive experimental tool for probing the molecular events involved in certain life processes.

This article discusses the fundamental nature of viruses: what they are, how they cause infection, and how they may ultimately cause disease or bring about the death of their host cells. For more detailed treatment of specific viral diseases, see the article INFECTIOUS DISEASES.

For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* sections 313 and 423.

The article is divided into the following sections:

GENERAL FEATURES

Definition. Viruses occupy a special taxonomic position: they are not plants, animals, or prokaryotic bacteria (single-cell organisms without defined nuclei), and they are generally placed in their own kingdom. In fact, viruses should not even be considered organisms, in the strictest sense, because they are not free-living (*i.e.,* they cannot reproduce and carry on metabolic processes without a host cell).

All true viruses contain nucleic acid, either DNA (deoxyribonucleic acid) or RNA (ribonucleic acid), and protein. The nucleic acid encodes the genetic information unique for each virus. The infective, extracellular (outside the cell) form of a virus is called the virion. It contains at least one unique protein synthesized by specific genes in the nucleic acid of that virus. In virtually all viruses, at least one of these proteins forms a shell (called a capsid) around the nucleic acid. Certain viruses also have other proteins internal to the capsid; some of these proteins act as enzymes, often during the synthesis of viral nucleic acids. Viroids (meaning "viruslike") are disease-causing organisms that contain only nucleic acid and have no structural proteins. Other viruslike particles called prions are composed primarily of a protein tightly complexed

Parasitic actions

with a small nucleic acid molecule. Prions are very resistant to inactivation and appear to cause degenerated brain disease in mammals, including humans.

Viruses are quintessential parasites; they depend on the host cell for almost all of their life-sustaining functions. Unlike true organisms, viruses cannot synthesize proteins, because they lack ribosomes (cell organelles) for the translation of viral messenger RNA (mRNA; a complementary copy of the nucleic acid of the nucleus, which associates with ribosomes and directs protein synthesis) into proteins. Viruses must use the ribosomes of their host cells to translate viral mRNA into viral proteins.

Viruses are also energy parasites; unlike cells, they cannot generate or store energy in the form of adenosine triphosphate (ATP). The virus derives energy, and all other metabolic functions, from the host cell. The invading virus uses the nucleotides and amino acids of the host cell to synthesize its nucleic acids and proteins, respectively. Some viruses use the lipids and sugar chains of the host cell to form their membranes and glycoproteins.

The true infectious part of any virus is its nucleic acid, either DNA or RNA but never both. In many viruses, but not all, the nucleic acid alone, stripped of its protein coat (capsid), can infect (transfect) cells, although considerably less efficiently than can the intact virions.

Capsid functions

The virion capsid has three functions: (1) to protect the viral nucleic acid from digestion by certain enzymes (nucleases), (2) to furnish sites on its surface that recognize and attach (adsorb) the virion to receptors on the surface of the host cell, and (3), in some viruses, to provide proteins that form part of a specialized component which enables the virion to penetrate through the cell surface membrane or, in special cases, to inject the infectious nucleic acid into the interior of the host cell.

Host range and distribution. Logic originally dictated that viruses be identified on the basis of the host they infect. This is justified in many cases, but not in others, and the host range and distribution of viruses are only one criterion for their classification. It is still traditional to divide viruses into three categories: those that infect animals, plants, or bacteria.

Virtually all plant viruses are transmitted by insects or other organisms (vectors) that feed on plants. The hosts of animal viruses vary from protozoa (single-celled animal organisms) to humans. Many viruses infect either invertebrate animals or vertebrates, and some infect both. Certain viruses that cause serious diseases of animals and humans are carried by arthropods. These vector-borne viruses multiply both in the invertebrate vector and the vertebrate host.

Certain viruses are limited in their host range to the various orders of vertebrates. Some viruses appear to be adapted for growth only in ectothermic vertebrates (animals commonly referred to as cold-blooded, such as fishes and reptiles), possibly because they can only reproduce at low temperatures. Other viruses are limited in their host range to endothermic vertebrates (animals commonly referred to as warm-blooded, such as mammals).

Size and shape. The amount and arrangement of the proteins and nucleic acid of viruses determine their size and shape. The nucleic acid and proteins of each class of viruses assemble themselves into a structure called a nucleoprotein, or nucleocapsid. Some viruses have more than one layer of protein surrounding the nucleic acid;

still others have a lipoprotein membrane (called an envelope), derived from the membrane of the host cell, that surrounds the nucleocapsid core. The protein and nucleic acid constituents have properties unique for each class of virus; when assembled, they determine the size and shape of the virus for that specific class.

Viruses vary in diameter from 20 nanometres (0.0000008 inch) to 250–400 nanometres. Only the largest and most complex viruses can be seen under the light microscope at the highest resolution. Any determination of the size of a virus also must take into account its shape, since different classes of viruses have distinctive shapes.

Size range

Shapes of viruses are predominantly of two kinds: rods, or filaments, so called because of the linear array of the nucleic acid and the protein subunits; and spheres, which are actually 20-sided (icosahedral) polygons. Most plant viruses are small and are either filaments or polygons, as are many bacterial viruses. The larger and more complex bacteriophages, however, contain as their genetic information double-stranded DNA and combine both filamentous and polygonal shapes.

Figure 1 shows the classical T4 bacteriophage, composed of a polygonal head, which contains the DNA genome, and a special-function rod-shaped tail of long fibres. Structures such as these are unique to the bacteriophages.

Animal viruses exhibit extreme variation in size and shape (Figure 2). The smallest animal viruses belong to the family Parvoviridae, which measure about 20 nanometres in diameter, and the family Picornaviridae, about 30 nanometres in diameter. Viruses of these two families are icosahedrons and contain nucleic acids with limited genetic information. Viruses of the family Poxviridae are about 250 to 400 nanometres in their longest dimension, and they are neither polygons nor filaments. Poxviruses are structurally more complex than, and resemble, simple bacteria. The only animal viruses that have rod-shaped (helical) nucleocapsids are those enclosed in an envelope; these viruses are found in the families Paramyxoviridae, Orthomyxoviridae, Coronaviridae, and Rhabdoviridae. Not all enveloped viruses contain helical nucleocapsids, however; those of the families Herpesviridae, Retroviridae, and Togaviridae have polygonal nucleocapsids. Most enveloped viruses appear to be spherical, although the rhabdoviruses are elongated cylinders.

The criteria used for classifying viruses into families and genera are primarily based on three structural considerations: (1) the type and size of their nucleic acid, (2) the shape and size of the capsids, and (3) the presence of a lipid envelope, derived from the host cell, surrounding the viral nucleocapsid.

Criteria of classification

The nucleic acid. As is true in all forms of life, the nucleic acid of each virus encodes the genetic information for the synthesis of all proteins. In almost all free-living organisms, the genetic information is in the form of double-stranded DNA arranged as a spiral lattice joined at the bases along the length of the molecule (a double-helix). Double-stranded DNA also carries the genetic information for some viruses, although probably in most the genetic information of the virion is RNA.

In extracellular virions, the DNA and RNA are called genomes, and they can be double- or single-stranded. In all double-stranded DNA viruses, the nucleic acid is a single large molecule. Most, if not all, of the double-stranded RNA viruses have segmented genomes; each segment usu-

ally is a single gene, which encodes the information for synthesizing a single protein. Those DNA viruses in which the genomic DNA is single-stranded are usually small, with limited genetic information. Some single-stranded DNA viruses are composed of two populations of virions, each consisting of complementary single-stranded DNA of polarity opposite to that of the other.

Positive-and negative-stranded RNA The virions of most plant viruses and many animal and bacterial viruses are composed of single-stranded RNA. In most of these viruses, the genomic RNA is termed a plus strand because the genomic RNA acts as mRNA for direct synthesis (translation) of viral protein. Several large families of animal viruses, and one that includes plant viruses (the Rhabdoviridae), however, contain genomic single-stranded RNA, termed a negative strand, which is complementary to mRNA. All of these negative-strand RNA viruses have an enzyme, called an RNA-dependent RNA polymerase (transcriptase), which must first catalyze the synthesis of complementary mRNA from the virion genomic RNA before viral protein synthesis can occur. These variations in the nucleic acids of viruses form one central criterion for classification of all viruses.

A distinctive large family of single-stranded RNA viruses is called Retroviridae; the RNA of these viruses is positive, but the viruses are equipped with an enzyme, called a reverse transcriptase, that copies the single-stranded RNA to form double-stranded DNA.

The protein capsid. The protein capsid provides the second major criterion for the classification of viruses. The capsid surrounds the virus and is composed of a finite number of protein subunits known as capsomers, which usually associate with, or are found close to, the virion nucleic acid.

There are two major classes of viruses based on the protein capsid: (1) those in which a single (or segmented) linear nucleic acid molecule with two free ends is essentially completely extended or somewhat coiled (a helix) and (2) those in which the nucleic acid, which may or may not be a covalently closed circle, is wound tightly into a condensed configuration, like a ball of yarn. These two classes of virus assume in the first case a long, extended rodlike structure and in the second case a symmetrical polygon. The helical nucleic acids of rod-shaped viruses are tightly enclosed in a sheath of protein molecules.

Major viral classes

By far the best-studied example of a helical rod-shaped virus is the tobacco mosaic virus, which was crystallized by Wendell Stanley in 1935. Figure 3 shows a model of the tobacco mosaic virus, the genome of which is single-stranded RNA encased by 2,130 molecules of a single protein; there are $16\frac{1}{3}$ protein molecules for each turn of the RNA helix in the ratio of three nucleotides for each protein molecule.

Under the right environmental conditions, viral RNA and protein molecules in liquid suspension will assemble themselves into a perfectly formed and fully infectious virus. The length of the virus capsid is determined by the length of the nucleic acid molecule, which is the framework for the assembly of the capsid protein. The various helical viruses have different lengths and widths depending on the size of the nucleic acid as well as on the mass and shape of the protein molecule. Some of these helical viruses form rigid, and others flexuous, rods, depending on the properties of the assembled proteins.

As shown in Figure 2, polygonal viruses vary greatly in size, from 20 to 150 nanometres in diameter, essentially proportional to the size of the nucleic acid molecule coiled up inside the virion. Most, if not all, of the polygonal viruses are icosahedral; like a geodesic dome, they are formed by equilateral triangles, in this case 20. Each tri-

Shapes of polygonal viruses

angle is composed of protein subunits (capsomers), often in the form of hexons (multiples of six) that are the building blocks of the capsid. There are 12 vertices (the apical junctions of these 20 triangles), each comprising a penton (five subunits). These icosahedral virions have three axes of fivefold, threefold, and twofold rotational symmetry (Figure 4). The number of subunits (capsomers) is a basis for taxonomic classification of these virus families. Certain icosahedral viruses, usually those that are more complex, contain internal proteins adhering to the nucleic acid that are not accessible at the surface of the virions.

The lipoprotein envelope. Surrounding viruses of either helical or icosahedral symmetry are lipoprotein envelopes, unit membranes of two lipid layers interspersed with protein molecules (lipoprotein bilayer). These viral membranes are composed of phospholipids and neutral lipids (largely cholesterol) derived from the cell membrane during the process known as the budding of the virus from the outermost cell membrane. Virtually all proteins of the cell membrane, however, are replaced by proteins of viral origin during budding. Although all the viral envelope lipids originate from the cell, their relative proportions vary from those in the cell membrane because the viral proteins select only certain lipids during budding.

Associated with the virion membrane are "integral" glycoproteins, which completely traverse the lipid bilayer,

Figure 4: A virus icosahedron (20-sided structure) shown in the (left) fivefold, (centre) threefold, and (right) twofold axes of symmetry. Edges of the upper and lower surfaces are drawn in solid and broken lines, respectively.

and "peripheral" matrix proteins, which line the inner surface. The glycoproteins contain regions of amino acids that, in the first step of viral infection, recognize host-cell receptors. Matrix proteins appear to function in the selection of regions of the cell membrane to be used for the viral membrane.

THE CYCLE OF INFECTION

Viruses can reproduce only within a host cell. The parental virus (virion) gives rise to numerous progeny, usually genetically and structurally identical to the parent virus. The actions of the virus depend both on its destructive tendencies toward a specific host cell and on environmental conditions. In the vegetative cycle of viral infection, multiplication of progeny viruses can be rapid. This cycle of infection often results in the death of the cell and the release of many virus progeny. Certain viruses, particularly bacteriophages, are called temperate because the infection does not immediately result in cell death. The viral genetic material remains dormant or is actually integrated into the genome of the host cell. Cells infected with temperate viruses are called lysogenic because the cells tend to be broken down when they encounter some chemical or physical factor, such as ultraviolet light. In addition, many animal and plant viruses, the genetic information of which is not integrated into the host DNA, may lie dormant in tissues for long periods of time without causing much, if any, tissue damage. Viral infection does not always result in cell death or tissue injury; in fact, most viruses lie dormant in tissue without ever causing pathological effects, or they do so only under other, often environmental, provocations.

Although the reproductive pathways of different viruses vary considerably, there are certain basic principles and a particular series of events in the cycle of infection for most, if not all, viruses. The first step in the cycle of infection is that the invading parental virus (virion) must attach to the surface of the host cell (adsorption). In the second step, the intact virion either penetrates the outer membrane and enters the cell's interior (cytoplasm), or it injects the genetic material of the virus into the interior of

the cell while the protein capsid (and envelope, if present) remains at the cell surface. In the case of whole-virion penetration, a subsequent process (uncoating) liberates the genetic material from the capsid and envelope, if present. In either case, the viral genetic material cannot begin to synthesize protein until it emerges from the capsid or envelope.

Certain bacterial viruses, such as the T4 bacteriophage, have evolved an elaborate process of infection: following adsorption and firm attachment of the virus's tail to the bacterium surface by means of proteinaceous "pins," the musclelike tail contracts and the tail plug penetrates the cell wall and underlying membrane and injects virus (phage) DNA into the cell (see Figure 1). Other bacteriophages penetrate the cell membrane by different means, such as injecting the nucleic acid through the male (sex) pili of the bacterium. In all bacterial viruses, penetration transmits the viral nucleic acid through a rigid bacterial cell wall.

Plant cells also have rigid cell walls, which plant viruses cannot ordinarily penetrate. Plant viruses, however, have not evolved their own systems for injecting nucleic acids into host cells, and so they are transmitted by the proboscis of insects that feed on plants. In the laboratory, plant viruses penetrate plant cells if the cell walls have been abraded with sandpaper or if cell protoplasts (plasma membrane, cytoplasm, and nucleus) are devoid of walls.

Penetration of animal cells by viruses involves different processes because animal cells are enclosed not by walls but by a flexible lipoprotein bilayer membrane. Most animal viruses, whether or not they are encased in lipid envelopes, penetrate cells in an intact form by a process called endocytosis (Figure 5). The membrane invaginates and engulfs a virus particle adsorbed to a cell, usually in an area of the membrane called a coated pit, which is lined by a special protein known as clathrin. As the coated pit invaginates, it is pinched off in the cytoplasm to form a coated vesicle. The coated vesicle fuses with cytoplasmic endosomes (membrane-enclosed vesicles) and then with cell organelles called lysosomes, which are membrane-enclosed vesicles containing enzymes. In an acidic environment, the membrane of an enveloped virus fuses with the endosome membrane, and the viral nucleocapsid is released into the cytoplasm. Nonenveloped viruses presumably undergo a similar process, by which the protein capsid is degraded, releasing the naked viral nucleic acid into the cytoplasm.

The order of the stages of viral replication that follows the uncoating of the genome varies for different virus classes. For many virus families the third step in the cycle of infection is transcription of the genome of the virus to produce viral mRNA, followed by the fourth step, translation of viral mRNA into proteins. For those viruses in which the genomic nucleic acid is an RNA that can serve as a messenger (*i.e.,* positive-strand RNA viruses), the third step is the translation of the RNA to form viral proteins; some of these newly synthesized viral proteins are enzymes that synthesize nucleic acids (polymerases),

Structure of viral envelopes

Adsorption
Endocytosis

Figure 5: Adsorption to and entry into a cell of an enveloped animal virus by the process of endocytosis into clathrin-coated vesicles, which fuse with large vesicles (endosomes and lysosomes). The process triggered by the viral glycoprotein results in fusion and release of the viral nucleocapsid into the cytoplasm.

which carry out a fourth step, the transcription of more mRNA from the viral genome. For the more complicated DNA viruses, such as adenoviruses and herpesviruses, some regions of the genome synthesize "early" mRNAs, which are translated into polymerases that initiate the transcription of "late" regions of the DNA into mRNAs, which are then translated into structural proteins.

"Early" mRNAs

Regardless of how the third and fourth steps proceed, the fifth step in the cycle of infection is replication (reproduction of the parental genome to make progeny genomes). The sixth step is the assembly of the newly replicated progeny genomes with structural proteins to make fully formed progeny virions. The seventh and last step is the release of progeny virions by lysis of the host cell through the process of either extrusion or budding, depending on the nature of the virus. In a host animal or cell culture this seven-step process may be repeated many times; the progeny virions released from the original site of infection are then transmitted to other sites or to other individuals.

For most animal and plant RNA viruses, all replicative events take place in the cytoplasm; in fact, many of these RNA viruses can grow in host cells in which the nucleus has been removed. Replication of most animal and plant DNA viruses, and the RNA influenza virus, takes place in the nucleus. In these viruses transcription takes place in the nucleus, the mRNA migrates to the cytoplasm where it is translated, and these viral proteins migrate back to the nucleus, where they assemble with newly replicated progeny genomes. Migration of newly translated proteins from the cytoplasm to the nucleus is generally a function of specific amino acid sequences called "signals," which translocate the protein through pores in the nucleus membrane.

VIRAL DNA INTEGRATION

Lysogeny. Many bacterial and animal viruses lie dormant in the infected cell, and their DNA may be integrated into the DNA of the host cell chromosome. The integrated viral DNA replicates as the cell genome replicates; after cell division, the integrated viral DNA is duplicated and usually distributed equally to the two cells that result. The bacteria that carry the noninfective precursor phage, called the prophage, remain healthy and continue to grow until they are stimulated by some perturbing factor, such as ultraviolet light. The prophage DNA is then excised from the bacterial chromosome and the phage replicates, producing many progeny phages and lysing the host bacterial cell. This process, originally discovered in temperate bacteriophages in 1950 by the French microbiologist André Lwoff, is called lysogeny.

λ bacterio-phage

The classic example of a temperate bacteriophage is called lambda (λ) virus, which readily causes lysogeny in certain species of the bacterium *Escherichia coli*. The DNA of the λ bacteriophage is integrated into the DNA of the *E. coli* host chromosome at specific regions, called attachment sites. The integrated prophage is the inherited, noninfectious form of the virus; it contains a gene that represses the lytic functions of the phage and thus assures that the host cell will continue to replicate the phage DNA along with its own and that it will not be destroyed by the virus. Ultraviolet light, or other factors that stimulate the replication of DNA in the host cell, causes the formation of a recA protease, an enzyme that breaks apart the λ phage repressor and induces λ phage replication and, eventually, destruction of the host cell.

Excision of the prophage DNA from the host chromosomal DNA (as an initial step in the synthesis of an infective, lytic virus) sometimes results in the removal of some of the host cell DNA, which is packaged into a defective bacteriophages; part of the bacteriophage DNA is removed and replaced at the other end by a gene of the host bacterium. Such a virus particle is called a transducing phage because, when it infects a bacterial cell, it can transmit the gene captured by λ phage DNA into the next bacterial cell it infects. Transduction by bacteriophages is an efficient means for transferring the genetic information of one bacterial cell to another.

Lysogenic conversion

This means of transferring genetic information, called lysogenic conversion, imparts genes with special functions to bacterial cells without such functions. It is common in bacteria and is an important aspect of the epidemiology (incidence, distribution, and control) of infectious diseases. For example, the bacterium *Corynebacterium diphtheriae* is the causative agent of diphtheria, but only when it contains the prophage of bacteriophage β, which codes for the toxin that is responsible for the disease.

Malignant transformation. A phenomenon analogous to bacterial cell lysogeny occurs in animal cells infected with certain viruses. These animal viruses do not generally cause disease immediately for certain animal cells. Instead, animal cells are persistently infected with such viruses, the DNA of which (provirus) is integrated into the chromosomal DNA of the host cell. In general, cells with integrated proviral DNA are converted into cancer cells, a phenomenon known as malignant transformation. As is the case with bacterial prophages, the transformed animal cell contains no infectious virus but only the integrated provirus DNA, which replicates along with the dividing cell's chromosomes. Therefore, following mitosis of the transformed cell, each new cell receives a copy of the proviral DNA. The hallmark of these transformed animal cells is that their growth is uncontrollable; unlike normal cells, their growth is not inhibited by contact with other cells, and they lose their capacity to adhere (anchor) to certain surfaces. Growth of normal tissues and organs is also controlled by a genetic phenomenon called programmed cell death, or apoptosis, in which a certain number of cells will die and be eliminated after a finite number of divisions. Malignant transformation can impede programmed cell death, thus allowing the cells to grow uncontrolled, resulting in cancer.

Programmed cell death

Among the animal viruses that cause malignant transformation by integration of proviral DNA are several families of DNA viruses and one large family of RNA viruses, the Retroviridae. Viruses of the family Papovaviridae were perhaps the first to be associated with malignancy (causing death or illness) in animals. Polyoma virus is widespread in mice; it can infect other rodents, and it can cause tumours in infected animals. Another virus of the family Papovaviridae is simian virus 40 (SV40), originally isolated from cells of the African green monkey (*Cercopithecus sabaeus*), where it grows rapidly and kills the cells. Infection of rodent or human cells, however, results in an abortive infection (an incompatibility between the virus and the host cell) but sometimes induces malignancy (sarcomas or lymphomas) in the occasional cell that is transformed. Viruses related to polyoma virus and SV40 have been isolated from humans, one of which, the JC virus, appears to be the causative agent of a fatal neurological disease called progressive multifocal leukoencephalopathy. In general, however, the human papovaviruses are not clearly associated with disease.

Other viruses of the family Papovaviridae include the papillomaviruses, which are also small polygonal viruses containing circular double-stranded DNA. The papillomaviruses are associated with usually benign (nonthreatening) but widespread tumours, called papillomas or polyps, occurring in human skin and the genital tract. Specific papillomaviruses have been identified in humans in common warts and in genital warts (condylomata acuminata). Cancers of the human genital tract, particularly uterine cancer of the cervix, are frequently found in association with human papillomavirus type 16 (HPV16); the virus undoubtedly is transmitted as a venereal disease.

Certain viruses of the family Adenoviridae (Figure 6), originally found in the tonsils and adenoids of humans, cause malignant transformation in certain cells. This phenomenon of cancer induction under laboratory conditions has been studied widely, but there is no evidence that the common adenoviruses cause cancers in humans. The common viruses of the family Herpesviridae, however, including the common herpes simplex viruses that cause cold sores and the venereal disease genital herpes, are suspected of being causative agents of cancer. Like the adenoviruses, the herpesviruses can cause malignant transformations, and their DNA is integrated into the host cell chromosome. A herpesvirus known as the Epstein-Barr virus causes a frequently fatal childhood cancer called Burkitt's

Herpes-viruses

lymphoma as well as the nonmalignant disease infectious mononucleosis. The herpesvirus cytomegalovirus lies dormant in the tissues of most humans and can be induced to cause fatal diseases in infants and immunocompromised adults. A different herpesvirus causes chicken pox (varicella); the same virus lies latent in the tissues for long periods of time (perhaps years or decades) and later undergoes recrudescence (the recurrence of symptoms after they have abated) to cause the painful skin and neurological disease called herpes zoster, or shingles. In addition, there are herpesviruses that cause disease in animals—for example, the widespread and usually fatal disease in chickens called Marek's disease. The widespread distribution of viruses of the family Herpesviridae is evident from other diseases in monkeys and frogs.

The viruses of the family Retroviridae are perhaps the most widely distributed of the transforming viruses that infect eukaryotic cells ranging from yeast to humans. It was suggested early in the 20th century that viruses cause leukemias and lymphomas in birds. In 1911 the American pathologist Peyton Rous first described a virus that causes sarcomas in chickens.

Retrovirus virions

The virions of retroviruses are spherical (or polygonal) and are surrounded by a lipid membrane containing a glycoprotein that recognizes and binds to cell receptors of a particular species (type-specific glycoproteins). Retrovirus genomes consist of two identical RNA molecules, each with 7,000 to 10,000 nucleotides. Associated with the virion RNA is an enzyme, an RNA-dependent DNA polymerase, also called a reverse transcriptase. Using the virion RNA as a template, the reverse transcriptase catalyzes the synthesis of a linear DNA molecule, complementary to the virion RNA. The new complementary strand of DNA also serves as a template for the reverse transcriptase, which makes a second anticomplementary DNA molecule, thus forming double-stranded DNA. The genomic RNA of fully infectious bird retroviruses, those that can replicate autonomously, has four genes that code sequentially for group-specific antigens, the reverse transcriptase, the envelope glycoprotein, and the sarcoma-transforming protein. At each end of the genome are homologous flanking nucleotide sequences, known as long terminal repeats (LTR), which code for double-stranded DNA that can recognize host cell DNA sequences for integration of the proviral DNA into the host cell chromosome. Many retroviruses are defective and cannot replicate in cells without helper (nondefective) retroviruses. The helper retroviruses generally transform fibroblastic cells, resulting in malignant sarcomas, whereas the defective retroviruses transform blood-cell precursors, resulting in leukemias.

Many different retroviruses have been identified as causative agents of cancers in birds, rodents (particularly mice), domestic cats, monkeys, and humans. Certain lymphatic leukemias in humans are caused by human T-cell leukemia virus (HTLV); acquired immune deficiency syndrome (AIDS) is caused by a retrovirus called human immunodeficiency virus (HIV).

Retroviruses originated from genes in many different species of animals and even lower forms of life. Individual retroviruses are limited in their host range and do not readily cross species barriers. Virtually every retrovirus studied to date is analogous to the genes normally found in animals (including humans), known as proto-onco-

Proto-oncogenes

genes, genes that are involved with regulating normal cell growth and development that also have the potential to change into cancer-causing genes. These proto-oncogenes have deoxynucleotide sequences closely, but not entirely, homologous (*i.e.*, of the same type and order) to the nucleotide sequences of a corresponding viral cancer-causing gene, called an oncogene. Integration of retrovirus DNA into cell chromosomes results in cancer, but the proto-oncogenes do not become cancer-causing genes unless triggered by another event. Cancers caused by chemical or physical carcinogens in the environment probably often, if not invariably, are due to alterations in the sequences of proto-oncogenes that have converted them to oncogenes. Some of the DNA tumour viruses, such as SV40 or adenoviruses, may induce malignant transformation when their DNA is integrated in proximity to the site of a proto-
Figure 6: The structure of an adenovirus showing its components and the polypeptides (proteins) exhibited by staining after electrophoresis.

From H. Persson and L. Philipson, *Current Topics in Microbiology and Immunology*, no. 97 (1982). Springer-Verlag

oncogene. All cancers studied to date appear to be due to either mutations in proto-oncogenes or the inheritance of mutated tumour suppressor genes, which normally regulate the function of proto-oncogenes.

DISEASE

Although viruses were originally discovered and characterized on the basis of the diseases they cause, most viruses that infect bacteria, plants, and animals (including humans) do not cause disease. In fact, bacteriophages may

Benefits of viruses

be helpful in that they rapidly transfer genetic information from one bacterium to another, and viruses of plants and animals may convey genetic information among similar species, helping their hosts survive in hostile environments. In the future this could also be true for humans. Recombinant DNA biotechnology shows great promise for the repair of genetic defects. Afflicted persons are injected with cells transformed by viruses that carry a functional copy of the defective human gene. The virus integrates the normal gene into the DNA of the human cell.

Of those viruses that cause disease, some cause short-term (acute) diseases and others recurring or long-term (chronic) diseases. Some viruses cause acute disease from which there is fairly rapid recovery but may persist in the tissues, remaining dormant for long periods of time, and then become active again, bringing about serious disease decades later. Slowly progressive viruses have long incubation periods before the onset of disease. As mentioned above, the DNA of certain viruses becomes integrated into the genome of the host cell, often resulting in malignant transformation of cells, which become cancers.

The nature of the disease caused by a virus is generally a genetic property of the virus as well as of the host cells. Almost all viruses, however, can remain dormant in the tissues of the host (latency). Viruses that cause acute disease are generally, but not always, those that rapidly harm or destroy cells (cytopathic effects) and have the capacity to shut off protein or nucleic acid synthesis within the host cell.

Human poliovirus and related picornaviruses that infect other animal species are examples of acute infectious agents that shut down protein synthesis in the host cell soon after infection; these picornaviruses also inhibit cellular RNA and DNA synthesis. Another virus that rapidly kills the infected cell is the negative-strand vesicular stomatitis virus (VSV) of the family Rhabdoviridae; viral RNA newly synthesized by infectious VSV rapidly shuts off cellular RNA synthesis and, to a somewhat lesser extent, cellular protein synthesis. In both poliovirus and VSV, the infected cell dies within hours of the inhibition of cellular RNA and protein synthesis. Other viruses that inhibit cellular macromolecule synthesis and produce acute infections include the poxviruses, reoviruses, togaviruses, adenoviruses, and herpesviruses; the latter two persist in host tissues for long periods of time and cause chronic infection as well. On the other hand, certain viruses, such

Human poliovirus

as the influenza viruses, do not have the drastic effects on the synthesis of cellular macromolecules, such as proteins, but they still cause acute, usually self-limiting, infections.

Many, if not most, diseases resulting from viral infection of vertebrates are caused not by a direct effect of the virus but rather by a secondary immune response. Essentially all viral proteins are recognized by vertebrate animals as immunologically foreign, and the immune systems of these animals mount two kinds of immune response, humoral and cellular. In humoral immunity, B lymphocytes, usually triggered by helper T lymphocytes, make antibodies (proteins that recognize and bind foreign molecules) to the viral protein. The antibody synthesized as a result of the immune response against a specific viral antigen usually benefits the infected host because that antibody can neutralize the infectivity of the specific virus in the blood and tissues of the infected host. Viruses inside the cell are not accessible to the antibody, because it cannot cross the cell membrane barrier.

In cellular immunity, a killer T cell recognizes and kills a virus-infected cell because of the viral antigen on its surface, thus aborting the infection because a virus will not grow within a dead cell. If the virus-infected cells are not essential for host functions, the killer T cell can prevent the spread of the infecting virus to other cells and distant tissues. Not infrequently, the virus-specific T lymphocyte kills vital cells such as nerve cells (neurons), muscle cells, and liver cells, all of which carry out important functions. In addition, the death of cells results in an inflammatory response, which also can damage vital tissues. Therefore, the cellular immune response to a viral infection can cause disease. In general, diseases caused by chronic viral infections, but also occasionally by subacute (between acute and chronic) viral infections, are caused by cellular immune responses that damage the virus-infected tissue.

Infectious patterns. Acute viral infections are of two types—local and systemic—both usually resulting from a direct effect of the invading virus on host tissue cells. Acute local infections generally occur at the site of viral infection. For example, acute respiratory infections include (1) the common cold, in which the rhinovirus infects only the nasal mucosa, (2) influenza, in which the virus is found in both nasal and bronchial mucosa, where severe damage can result in death, (3) grippelike illnesses caused by adenoviruses localized in lymphoid tissue of the throat (although infection also can occur in the intestine and the eye or be spread to the heart), and (4) severe respiratory infections of infants and children, caused by parainfluenza viruses or respiratory syncytial viruses, which cause severe croup that may be life-threatening. Examples of acute infections localized to the intestine include those that result in enteritis (bowel inflammation), which may be accompanied by diarrhea; these are often caused by rotoviruses and coronaviruses.

Many viruses transmitted by the respiratory route (from sneezes and coughs, for example) and limited to humans begin their cycle of infection in the upper respiratory tract (nose and throat) and then enter the bloodstream, where they are spread to distant tissues. Examples of such diseases are measles, mumps, and chicken pox, in which the growth of the specific virus in the mucosal cells of the throat during the first few days of infection usually results in mild fever and achiness; this stage is called the prodromal period of the illness. During the next few days the virus enters the draining lymph nodes and then the bloodstream, where it is spread throughout the tissues of the body, resulting in fever and rash (in the case of measles and chicken pox) and inflammation of the parotid glands and, less frequently, the testes, ovaries, and joints (in the case of mumps). Varicella (chicken pox) virus rarely causes pneumonia, but all these viruses can cause meningitis and, rarely, encephalitis. A similar pattern of infection formerly occurred with smallpox, a disease that was more frequently fatal but now, ostensibly, has been eradicated.

A large number of viruses of the digestive tract (enteroviruses), among them poliovirus, Coxsackie viruses, and echoviruses (enteric cytopathic human orphan virus), also cause a two-phase illness. Enteroviruses grow initially in the intestinal tract and are transmitted by mouth

through water, food, and other materials contaminated with feces. The viruses are resistant to the acid normally found in the stomach and thus reach the intestinal tract, where they multiply in living mucosal cells. This initial period of viral invasion and growth in the intestine causes either an initial mild febrile illness or is asymptomatic. Over the next few days these enteroviruses are spread from the intestinal mucosa to the draining lymph nodes, from which they invade the bloodstream, resulting in a condition known as viremia. From the bloodstream the viruses are widely spread to all tissues, but in most cases no symptomatic disease occurs. Poliovirus in less than 1 percent of cases affects the spinal cord or brain, resulting in paralysis or death. Different types of Coxsackie viruses and echoviruses can cause acute, usually nonfatal, illnesses such as meningitis, carditis, pleurisy, or rashes.

Many viral diseases are transmitted by bites of insects or other arthropods, and these infections usually begin in the skin or lymph nodes and rapidly invade the bloodstream. The nature of the disease caused by these arthropod-borne viruses (arboviruses) is determined by the affinity (tropism) of each virus for specific organs. Many that have an affinity for brain tissue cause encephalitis or meningitis, but others primarily infect the muscles, liver, heart, or kidneys. Virtually all these diseases are epidemic in character, and the viruses that cause them are the primary pathogens of birds and mammals. The insect, usually a certain species of mosquito, takes a blood meal from the infected host bird or mammal and shortly thereafter bites a human, thus transmitting the virus. These arboviruses do not ordinarily multiply in the insect but simply reside on its proboscis. Examples of human epidemic diseases resulting from transmission of these arboviruses are encephalitis caused by viruses of the family Togaviridae and Flaviviridae and often fatal, yellow fever and dengue caused by viruses of the family Flaviviridae, and hemorrhagic fevers caused by viruses of the families Bunyaviridae and Arenaviridae. Of considerable interest and concern are the identification of new strains of viruses, particularly a hantavirus of the Bunyaviridae family that is responsible for an epidemic in the early 1990s in the southwestern United States that resulted in considerable numbers of fatal human infections.

Latency. Inapparent infections (those that do not cause specific signs and symptoms) often result after exposure to picornaviruses, influenza viruses, rhinoviruses, herpesviruses, and adenoviruses but less frequently to measles and chicken pox viruses. In cases of inapparent infection, long-lasting immunity develops, but only to the strain of virus that has the same antigenic composition as the original infecting virus.

Certain of these viruses persist in the tissues of the host after the initial infection despite the presence of circulating antibodies to it in the blood and tissues. Such viruses probably reside inside cells, where they are protected from antibodies that cannot penetrate the cell membrane. Among persistent viruses are adenoviruses, measles virus, and, in particular, many kinds of herpesviruses. The genetic information of herpesviruses and adenoviruses can be integrated into the genome of the host cell, but it is believed that these viruses frequently, and the measles virus invariably, reside in cells in the form of extrachromosomal genes (genes not integrated in chromosomes). These dormant viruses can be activated by many factors, such as trauma, another infection, emotional stress, menstruation, excessive exposure to sunlight, and various illnesses.

The phenomenon of latency and reactivation is particularly common among viruses of the family Herpesviridae, which cause chronic or recurrent diseases: (1) herpes simplex virus type 1, which causes recurrent cold sores, (2) herpes simplex virus type 2 in genital tissue, which causes repeated herpetic infections of the vagina or penis, (3) cytomegalovirus, which usually produces an inapparent infection activated by simultaneously occurring disease to cause severe liver, lung, or nervous-system disease, and (4) varicella virus, which is the causative agent of chicken pox but which can be activated decades later to produce herpes zoster (shingles). A rare, but invariably fatal, disease of the nervous system is subacute sclerosing panencephalitis (SSPE), which is a progressive, degenerative condition

Local and systemic infection

Route of enteroviruses

caused by measles virus (a paramyxovirus) lying dormant in brain cells for many years and then reactivated, usually in adolescence. There is no simple explanation why latent viruses, such as those in the family Herpesviridae, that are present in the tissues of most adult humans can be activated to cause disease in some people but not in others.

Chronic and slowly progressive diseases. Although some viruses multiply slowly, this is not always the explanation for the chronicity or the slow progression of the diseases caused by these viruses. Hepatitis, for example, is a subacute or chronic disease, with a long latent period, that is caused by at least five viruses with different properties. Hepatitis A is caused by a picornavirus usually transmitted by the fecal-oral route in a manner similar to that of poliovirus. Hepatitis B is caused by a small DNA virus that contains its own DNA polymerase and is transmitted by transfusion of blood and other blood products, by the sharing of nonsterile hypodermic needles among drug users, by sexual intercourse, or from mother to neonate. Hepatitis B virus is classified with similar viruses of birds in the family Hepadnaviridae. Most cases of hepatitis spread by the transfusion of blood or blood products or by needles shared by drug users are caused by a third, completely distinct virus, originally called non-A, non-B hepatitis but now known to be a member of the virus family Flaviviridae designated hepatitis C virus. A fourth unique agent that causes hepatitis is designated hepatitis delta virus, which has not yet been classified taxonomically but is a small, enveloped virus containing a circular RNA genome; hepatitis B virus serves as a helper for replication of hepatitis delta virus, the virions of which contain hepatitis B surface antigen (HB_sAg). The fifth causative agent of viral hepatitis, largely occurring in Asia and Africa, is a small RNA virus tentatively classified as a member of the family Caliciviridae and designated hepatitis E virus.

Neurological diseases

Many other agents that appear to cause chronic and slowly progressive diseases, particularly those affecting the nervous system, have been tentatively identified. A fatal neurological disorder of sheep, called scrapie, has an incubation period of years and may be caused by a heat-resistant protein complexed with nucleic acid, called a prion, which is postulated to activate latent genes that cause the disease. Similar, rather obscure agents have been identified for two uncommon, fatal disorders of the nervous system, called Creutzfeldt-Jakob disease and kuru.

The disease now known as AIDS was first recognized in homosexuals and hemophiliacs about 1981 and continues to be disseminated throughout the world to become one of the most devastating epidemics of all time. AIDS is caused by HIV, a member of a genetically more complex group of the family Retroviridae called lentiviruses. Closely related viruses of monkeys and cats cause similar diseases. HIV is transmitted by blood and other body fluids and infects primarily helper T lymphocytes and other cells with CD4 surface receptors, to which the virus binds. After the virus has been dormant for years, destruction of T lymphocytes results in drastic depression of the immune system. Death almost invariably results from "opportunistic" infections such as pneumonia—caused by ordinarily nonpathogenic organisms such as *Pneumocystis carinii*—or tuberculosis or by cancers such as Kaposi's sarcoma and lymphomas.

Prevention. The spread of many viral diseases can be prevented by hygienic factors such as efficient sanitation facilities, effective waste disposal, clean water, and personal cleanliness. Active immunization by vaccines (antigen-containing preparations that elicit the synthesis of antibodies and thus immunity) has been useful in preventing common epidemics caused by acutely infectious viruses.

Vaccination

The best example of such a preventable disease is smallpox, caused by a disease-producing virus that at one time was found worldwide. In 1798 the English physician Edward Jenner discovered that the milder cowpox virus could serve as a live vaccine (an antigenic preparation consisting of viruses whose disease-producing capacity has been weakened) for preventing smallpox. The program of vaccination that resulted from Jenner's discovery is one of the greatest success stories in the annals of medicine; in 1980 the World Health Organization declared that the disease had been eliminated.

A different prospect is presented by rabies, an invariably fatal viral disease mentioned in ancient Greek literature and in the Bible. Transmitted by the bite of dogs and other domestic and wild animals, the rabies virus is more difficult to eradicate because it is present in wild animals throughout the world, except in certain island countries such as Great Britain and Australia. Influenza virus is also distributed worldwide, but, of the three major immunologic types, only one (type A) is responsible for large epidemics. The worldwide epidemic (pandemic) of influenza at the end of World War I is estimated to have caused 20 million deaths, mostly of adolescents and young adults. Because of virus mutations that produce minor antigenic changes every few years and major antigenic shifts about every 10 years, influenza viruses have the capacity to resist inactivation by antibodies acquired by previous infection or vaccination. Development of effective vaccines to combat influenza is a difficult task, although existing vaccines are partially effective and are recommended for people at high risk (*i.e.*, the elderly and those with chronic disease of the respiratory or circulatory systems).

Poliomyelitis

Vaccines are most successful when directed against those viruses that do not mutate and that infect only humans. In addition to smallpox, a successful vaccine program has been carried out against poliomyelitis. Polioviruses exist in only three antigenic types, each of which has not changed significantly for decades. The vaccines available are the "killed" (Salk) vaccine, composed of inactivated virus of the three types, and the "live" (Sabin) vaccine, composed of genetically attenuated viruses of the three types. These vaccines, which were introduced in the 1950s, have lowered the incidence in developed countries of paralysis resulting from poliomyelitis. The disease still occurs in developing countries and recurs in some developed countries where vaccination programs have not been enforced. Rare cases of poliomyelitis occur, particularly in the United States, from the Sabin vaccine strain of type-3 poliovirus, which is genetically unstable and occasionally reverts to the virulent form.

Vaccination can prevent diseases caused by strictly human viruses that exist in only one antigenic and stable type. Measles has been prevented in developed countries with routine vaccination. Measles, however, may still be the major cause of death in children in developing countries. Vaccination for mumps and chicken pox promises to be successful because the causative viruses of these diseases show little tendency to vary antigenically and are confined to humans. On the other hand, development of vaccines for the common cold caused by rhinoviruses, similar to polioviruses, will be a formidable, if not impossible, task because there are at least 100 antigenic types of the rhinovirus. Also daunting is the task of developing a vaccine against HIV. The major antigenic component of this virus is a surface membrane-inserted glycoprotein (gp120), which has a startling rate of mutation. The extreme antigenic diversity that results from the mutability of the gene that codes for this protein would prevent HIV from being identified and attacked by circulating antibodies or killer T lymphocytes.

Treatment. Unlike bacteria, viruses mimic the metabolic functions of their host cells. Antibiotics and other antimicrobial agents are, therefore, ineffective against viruses because the chemical compounds that inhibit the multiplication of viruses generally also slow the functions of, and are toxic to, the host cell. The only chemotherapeutic agents (drugs used to control or eliminate disease) that exert a selectively greater effect on viral replication than they do on cell replication are certain synthetic compounds, such as ribavirin, acyclovir, or zidovudine (azidothymidine [AZT]). These drugs have been partially effective in improving, if not curing, viral diseases without causing major toxic side effects. AZT has been used with some success in prolonging the lives of patients with AIDS.

Interferons

Certain natural products of cells, called interferons, may have potential antiviral and anticancer properties. Interferons are proteins normally synthesized by the cells of vertebrates, including humans, either intrinsically and without stimulation or in response to certain viral infections, chemicals, or immune reactions. In general, the

multiplication of viruses is inhibited by interferons, some to a much greater extent than others. Interferons are generally species-specific; *i.e.*, they are effective in inhibiting viral infection only in cells of the same species that naturally synthesize the interferon.

There are three classes of interferons: α-interferons, produced by blood leukocytes; β-interferons, produced by tissue cells and fibroblasts; and γ-interferons (also called immune interferons or interleukins), produced by immune reactions in blood lymphocytes. Interferons are now known to be a subset of a large group of natural cellular substances called cytokines, which signal cells to perform specific functions. Until recently, interferons were difficult to produce commercially because cells and tissues synthesize only small amounts of them. Through recombinant DNA technology, however, large amounts of interferon can be produced.

There has been some success in using interferons to treat viral diseases, such as colds caused by rhinoviruses, infections caused by herpesviruses, and benign tumours and warts caused by papillomaviruses. Local administration at the sites of viral infection affords the best results, although injections of large amounts of interferons can be harmful, probably because they tend to inhibit protein synthesis in the host cell.

EVOLUTION

Owing to their simplicity, viruses were at first considered to be the primordial life-forms. This concept is almost certainly incorrect because viruses are completely devoid of the machinery for life processes; therefore, they could not have survived in the absence of cells. Viruses probably evolved from cells rather than cells from viruses. It seems likely that all viruses trace their origins to cellular genes and can be considered as pieces of rogue nucleic acids. Although it is easier to imagine the cellular origin of DNA viruses than RNA viruses, the RNA viruses conceivably could have had their origins from cellular RNA transcripts made from cellular DNA. In fact, the discovery that many cells contain reverse transcriptase capable of converting RNA to DNA seems to suggest that conversion of RNA to DNA and DNA to RNA is not rare. Indeed, some speculate that RNA is the primordial genetic information from which DNA evolved to produce more complex life-forms.

Other possible progenitors of viruses are the plasmids (small circular DNA molecules independent of chromosomes), which are more readily transferred from cell to cell than are chromosomes. Theoretically, plasmids could have acquired capsid genes, which coded for proteins to coat the plasmid DNA, converting it into a virus.

In brief, it is likely that viruses originated from the degradation of cellular nucleic acids, which acquired the property of being readily transferable from cell to cell during the process of evolution. The fact that normal proto-oncogenes of a cell have nucleic acid sequences that are almost identical to the oncogenes of retroviruses lends credence to the theory that viruses originated from cellular genes.

CLASSIFICATION

Distinguishing taxonomic features. Viruses are classified on the basis of their nucleic acid content, their size, the shape of their protein capsid, and the presence of a surrounding lipoprotein envelope.

The primary taxonomic division is into two classes based on nucleic acid content: DNA viruses or RNA viruses. The DNA viruses are subdivided into those that contain either double-stranded or single-stranded DNA. The RNA viruses also are divided into those that contain double-stranded or single-stranded RNA. Further subdivision of the RNA viruses is based on whether the RNA genome is segmented or not. If the viruses contain single-stranded RNA as their genetic information, they are divided into positive-strand viruses if the RNA is of messenger sense (directly translatable into proteins) or negative-strand viruses if the RNA must be transcribed by a polymerase into mRNA.

All viruses falling into one of these nucleic acid classifications are further subdivided on the basis of whether the nucleocapsid (protein coat and enclosed nucleic acid)

assumes a rodlike or a polygonal (usually icosahedral) shape. The icosahedral viruses are further subdivided into families based on the number of capsomers making up the capsids. Finally, all viruses fall into two classes depending on whether the nucleocapsid is surrounded by a lipoprotein envelope.

Some virologists adhere to a division of viruses into those that infect bacteria, plants, or animals; these classifications have some validity, particularly for the unique bacterial viruses with tails, but there is otherwise so much overlap that taxonomy based on hosts seems unworkable. Classification based on diseases caused by viruses also is not tenable, because closely related viruses frequently do not cause the same disease. Eventually, it is likely that the classification of viruses will be based on the nucleotide sequences of their nucleic acids rather than on structural components, as is now the case.

The basic taxonomic group is called a family, designated by the suffix -viridae. The major taxonomic disagreement among virologists is whether to segregate viruses within a family into a specific genus and further subdivide them into species names. Most virologists believe that a binomial nomenclature, as used for bacteria, into italicized and Latinized genera and species is unwarranted. For this reason, no Latin names are used in the classification of viruses presented here. Moreover, only the well-characterized viruses of animals are presented (see Figure 2).

Annotated classification.

DNA viruses

FAMILY POXVIRIDAE

Large viruses of complex structure with dimensions of 400×200 nm, the genome of which is linear double-stranded DNA. Virions contain at least 40 proteins and lipid, as well as internal structures called lateral bodies. The 2 subfamilies are called Chordopoxvirinae, which infect vertebrates and are closely related antigenically, and Entomopoxvirinae, which infect arthropods. The Chordopoxvirinae are composed of groups called orthopoxviruses (vaccinia), parapoxviruses, avipoxviruses of birds, and many others that infect sheep, rabbits, and swine.

FAMILY ADENOVIRIDAE

Nonenveloped virions of icosahedral symmetry, about 80 nm in diameter, and capsids containing 252 capsomers with 12 vertices to which are attached glycoprotein fibres 10–30 nm in length with knobs at the ends (see Figure 6). The genome is linear double-stranded DNA. Classified in 2 subgroups: Mastadenoviruses, which infect mammals, and Aviadenoviruses, which infect birds. Common acute respiratory and gastrointestinal pathogens of humans, and some types cause malignant transformation of cultured cells and can cause cancer in animals.

FAMILY HERPESVIRIDAE

Icosahedral virion with capsid about 105 nm in diameter and 162 capsomers surrounded by a floppy envelope containing glycoprotein spikes. Genome composed of linear double-stranded DNA. There are 3 known subfamilies: Alphaherpesvirinae, consisting of human herpes simplex viruses types 1 and 2, bovine mamillitis virus, SA 8 virus and monkey B virus, pseudorabies virus, equine herpesvirus, and varicellazoster virus; Betaherpesvirinae, composed of species of cytomegaloviruses; and Gammaherpesvirinae, composed of genera familiarly called Epstein-Barr virus, baboon herpesvirus, chimpanzee herpesvirus, Marek's disease virus of chickens, turkey herpesvirus, herpesvirus saimiri, and herpesvirus ateles.

FAMILY IRIDOVIRIDAE

Large enveloped or nonenveloped icosahedral virions measuring 130–150 nm in diameter and containing linear double-stranded DNA. Genera include iridovirus and chloridirovirus, which infect insects, African swine fever virus, and lymphocystic disease virus.

FAMILY HEPADNAVIRIDAE

Small enveloped spherical virions about 42 nm in diameter containing circular double-stranded DNA with a single-stranded DNA region and a DNA-dependent DNA polymerase that repairs the single-stranded DNA gap and is essential for replication. Also characteristic are the use of reverse transcriptase for replication and an abundance of a soluble protein (HB$_s$Ag). Genera include human hepatitis B virus, woodchuck hepatitis virus, ground squirrel hepatitis virus, duck hepatitis virus, and several others thus far less well documented.

FAMILY PAPOVAVIRIDAE

Icosahedral, nonenveloped virions with 72 capsomers comprising 2 genera: the polyomaviruses (SV40 and polyoma virus), measuring 45 nm in diameter; and the papillomaviruses, mea-

suring 55 nm in diameter. Virions of both genera contain covalently linked circular DNA. The polyomaviruses produce malignant transformation of infected cells, whereas the papillomaviruses, which do not grow in cell culture, usually cause warts and benign papillomas, which can also lead to cancer.

FAMILY PARVOVIRIDAE

Small icosahedral, nonenveloped virions with 32 capsomers measuring 18–26 nm in diameter that contain single-stranded DNA. Viruses of this family infect vertebrates and insects, the latter sometimes designated densoviruses. The vertebrate viruses fall into 2 classes: those that replicate autonomously and those that replicate only in the presence of helper adenoviruses or herpesviruses, designated adenoassociated viruses (AAV) or dependoviruses.

RNA viruses

FAMILY PICORNAVIRIDAE

Small icosahedral, nonenveloped virions 27–30 nm in diameter, composed of 60 capsomers and containing nonsegmented single-stranded, plus-strand RNA. There are 4 recognized genera designated enteroviruses (polioviruses, Coxsackie viruses, echoviruses), cardioviruses, rhinoviruses (common cold viruses), and aphthoviruses (foot-and-mouth disease virus of cattle).

FAMILY CALICIVIRIDAE

Icosahedral, nonenveloped virions about 38 nm in diameter, composed of 32 capsomers and 180 molecules of a single capsid protein. The genome consists of single plus-strand RNA. The prototype virus of this family is the vesicular exanthema of swine virus.

FAMILY TOGAVIRIDAE

Small enveloped virions spherical in shape with icosahedral nucleocapsid of 32 capsomers about 30 nm in diameter. The genome is single plus-strand RNA. There are 2 recognized genera: 1 transmitted by arthropods (exclusively mosquitoes) and designated alphaviruses (prototypes Sindbis virus, eastern and western equine encephalitis viruses), the other nonarthropodborne and designated rubivirus (the causative agent of German measles).

FAMILY FLAVIVIRIDAE

Viruses of this family are enveloped and spherical in shape, with a genome consisting of nonsegmented single plus-strand RNA. These viruses are transmitted by either insects or arachnids and cause severe diseases such as yellow fever, dengue, tick-borne encephalitis, and Japanese B encephalitis. Recently characterized members of this family are nonarthropod-borne hog cholera virus (pestivirus) and hepatitis C virus of humans.

FAMILY CORONAVIRIDAE

Enveloped virions 60–220 nm in diameter with helical nucleocapsid containing single plus-strand RNA genome. Clubshaped glycoprotein spikes in envelope give crownlike (coronal) appearance. Viruses of this family are important agents of gastrointestinal disease in humans, poultry, and bovines.

FAMILY ORTHOMYXOVIRIDAE

Enveloped virions about 100 nm in diameter with helical nucleocapsid containing 8 segments of negative-strand RNA and endogenous RNA polymerase. The lipoprotein envelope contains 2 glycoproteins, designated hemagglutinin (major antigen) and neuraminidase. The only viruses in this family are influenza viruses of 3 distinct antigenic types (A, B, and C).

FAMILY PARAMYXOVIRIDAE

Enveloped virions varying in size from 150 to 300 nm in diameter with a helical nucleocapsid containing a single negativestrand nonsegmented RNA and an endogenous RNA polymerase. The lipoprotein envelope contains 2 glycoprotein spikes designated hemagglutinin-neuraminidase (HN) and fusion factor (F). The major genus is paramyxovirus and is composed of human parainfluenza viruses and mumps virus, as well as Newcastle disease virus of poultry. The genus morbillivirus contains the agents that cause measles in humans, distemper in dogs and cats, and rinderpest in cattle. The third genus, pneumovirus, causes the serious respiratory syncytial virus disease in human infants and is also classified in the subfamily Pneumovirinae.

FAMILY RHABDOVIRIDAE

Enveloped virions, usually bullet-shaped, $180-300 \times 65$ nm, containing a helical nucleocapsid with single minus-strand RNA and an endogenous RNA polymerase. The lipoprotein envelope contains a single glycoprotein, which is the type-specific antigen. Viruses of this family are widely infectious for plants and for animals varying from insects to humans. Two animal genera are designated vesiculovirus, which includes the virus that causes vesicular stomatitis in cattle, swine, and equines, and lyssavirus, which includes the causative agent of rabies.

FAMILY FILOVIRIDAE

Enveloped virions, variably elongated filaments 650–14,000 nm in length and pleomorphic in shape, containing a helical nucleocapsid with single minus-strand RNA (about 19 kilobases in length), and an endogenous RNA polymerase. Much like the Rhabdoviridae, the lipoprotein envelope contains a single glycoprotein, which is the type-specific antigen. The family consists of 1 genus, filovirus, that contains the Marburg virus and Ebola viruses. These viruses have been isolated from African monkeys, and both are among the most dangerous pathogens. Some strains cause severe hemorrhagic fevers in humans; the mortality rate from these diseases is as high as 88 percent. Human infections with Marburg virus have been traced to laboratory monkeys, but human outbreaks of fatal Ebola virus infection in Zaire and The Sudan have not been traced to monkeys.

FAMILY ARENAVIRIDAE

Enveloped virions 100–200 nm in diameter with a helical nucleocapsid in 2 segments containing minus-strand RNA, an endogenous RNA polymerase, and small amounts of ribosomal RNA. There are 4 genera, with viruses widely distributed in animals and causing serious human diseases, many transmitted by insects.

FAMILY BUNYAVIRIDAE

Enveloped virions about 95 nm in diameter with a 3-segment helical nucleocapsid containing single-stranded RNA of negative sense and endogenous RNA polymerase. There are many viruses (about 350 species) grouped in 5 genera: bunyavirus, phlebovirus, nairovirus, taspovirus, and hantavirus. Most of these viruses are transmitted by arthropods and cause serious human disease.

FAMILY RETROVIRIDAE

Enveloped virions about 90 nm in diameter with 2 identical copies of single plus-strand RNA in nondefective virions and a reverse transcriptase, which promotes synthesis of doublestranded DNA from the viral RNA template. A hallmark of the virion RNA templates is long terminal repeat (LTR) nucleotide sequences, which serve for integration of the DNA in chromosomes of the host cell. Retroviridae cause cancers in many species of animals, including humans, and are probably derived from normal cell nucleotide sequences called proto-oncogenes. Certain retroviruses of the lentivirus group cause AIDS in humans, monkeys, felines, and cattle.

FAMILY REOVIRIDAE

Nonenveloped icosahedral virions with outer and inner protein shells 60–80 nm in diameter and containing double-stranded RNA in 10 to 12 segments. Viruses in this family infect many species of plants and animals. The animal Reoviridae are divided into 4 genera, designated orthoreoviruses, orbiviruses (widely distributed in insects and vertebrates, including bluetongue virus disease of sheep), rotaviruses (widespread causative agents of gastroenteritis in mammals, including humans), and cypoviruses (prototype causes cytoplasmic polyhedrosis disease in insects).

BIBLIOGRAPHY. Descriptions of the diseases and their epidemiology are included in BERNARD N. FIELDS and DAVID M. KNIPE (eds.), *Fields Virology,* 2nd ed., 2 vol. (1990), a text on the structure, biological properties, replication, and immunology of virtually all human viruses of medical importance. DAVID O. WHITE and FRANK J. FENNER, *Medical Virology,* 4th ed. (1994), is intended for medical students and other health professionals. *The Viruses,* 24 vol. (1982–94), a monographic series, critically analyzes in detail the biology, chemistry, and physical properties of each family of viruses—*e.g.,* BERNARD ROIZMAN and CARLOS LOPEZ (eds.), *The Herpesviruses,* 4 vol. (1982–85); and JAY A. LEVY (ed.), *The Retroviridae,* 3 vol. (1992–94). C.H. ANDREWES, *The Natural History of Viruses* (1967), offers a personal account by one of the pioneers in the field. ARNOLD J. LEVINE, *Viruses* (1992), a beautifully illustrated and well-written history and description of virology, provides insight into its scientific development. SHERWOOD CASJENS (ed.), *Virus Structure and Assembly* (1985), contains an illustrated series of essays by some of the major contributors to the understanding of the physical principles that determine the structure and assembly of viruses. ABNER LOUIS NOTKINS and MICHAEL B.A. OLDSTONE (eds.), *Concepts in Viral Pathogenesis* (1984), *Concepts in Viral Pathogenesis II* (1986), and *Concepts in Viral Pathogenesis III* (1989), contain a detailed series of chapters by leading investigators on the disease-causing properties of many pathogenetic viruses. The international classification of the families, genera, species, and strains of all viruses discovered by 1991 may be found in R.I.B. FRANCKI *et al.* (eds.), *Classification and Nomenclature of Viruses* (1991). ROBERT G. WEBSTER and ALLAN GRANOFF (eds.), *Encyclopedia of Virology,* 3 vol. (1994), contains extremely well-annotated descriptions of every known virus in alphabetical order by common names with detailed indexes and tables.   (R.R.W.)

Volcanism

A volcano is a vent in the crust of the Earth or other planet or satellite, from which issue eruptions of molten rock, hot rock fragments, and hot gases. A volcanic eruption is an awesome display of the Earth's power. Yet while eruptions are spectacular to watch, they can cause disastrous loss of life and property, especially in densely populated regions of the world. Sometimes beginning with an accumulation of gas-rich magma (molten underground rock) in reservoirs near the surface of the Earth, they can be preceded by emissions of steam and gas from small vents in the ground and by a swarm of small earthquakes. In some cases, magma rises in conduits to the surface as a thin and fluid lava, either flowing out continuously or shooting straight up in glowing fountains or curtains. In other cases, entrapped gases tear the magma into shreds and hurl viscous clots of lava into the air. In more violent eruptions, the magma conduit is cored out by an explosive blast, and solid fragments are ejected in a great cloud of ash-laden gas that rises tens of thousands of metres into the air. One feared phenomenon accompanying some explosive eruptions is the *nuée ardente*, or pyroclastic flow, a fluidized mixture of hot gas and incandescent particles that sweeps down a volcano's flanks, incinerating everything in its path. Great destruction also can result when ash collects on a high snowfield or glacier, melting large quantities of ice into a flood that can rush down a volcano's slopes as an unstoppable mudflow.

Strictly speaking, the term *volcano* means the vent from which magma and other substances erupt to the surface, but it can also refer to the landform created by the accumulation of solidified lava and volcanic debris near the vent. One can say, for example, that large lava flows erupt from Mauna Loa volcano in Hawaii, referring here to the vent; but one can also say that Mauna Loa is a gently sloping volcano of great size, the reference in this case being to the landform. Volcanic landforms have evolved over time as a result of repeated volcanic activity. Mauna Loa typifies a shield volcano, which is a huge, gently sloping landform built up of many eruptions of fluid lava. Mount Fuji in Japan is an entirely different formation. With its striking steep slopes built up of layers of ash and lava, Mount Fuji is a classic stratovolcano. Iceland provides fine examples of volcanic plateaus, while the seafloor around Iceland provides excellent examples of submarine volcanic structures.

Volcanoes figure prominently in the mythology of many peoples who have learned to live with eruptions, but science was late in recognizing the important role of volcanism in the evolution of the Earth. As late as 1768, the first edition of *Encyclopædia Britannica* gave voice to a common misconception by defining volcanoes as "burning mountains, which probably are made up of sulphur and some other matter proper to ferment with it, and take fire." Today geologists agree that volcanism is a profound process resulting from the thermal evolution of planetary bodies. Heat does not easily escape from large bodies such as the Earth by the processes of conduction or radiation. Instead, heat is transferred from the Earth's interior largely by convection—that is, the partial melting of the Earth's crust and mantle and the buoyant rise of magma to the surface. Volcanoes are the surface sign of this thermal process. Their roots reach deep inside the Earth, and their fruits are hurled high into the atmosphere.

Volcanoes are closely associated with plate tectonic activity. Most volcanoes, such as those of Japan and Iceland, occur on the margins of the enormous solid rocky plates that make up the Earth's surface. Other volcanoes, such as those of the Hawaiian Islands, occur in the middle of a plate, providing important evidence as to the direction and rate of plate motion.

The study of volcanoes and their products is known as volcanology, but these phenomena are not the realm of any single scientific discipline. Rather, they are studied by many scientists from several specialties: geophysicists and geochemists, who probe the deep roots of volcanoes and monitor signs of future eruptions; geologists, who decipher prehistoric volcanic activity and infer the likely nature of future eruptions; biologists, who learn how plants and animals colonize recently erupted volcanic rocks; and meteorologists, who determine the effects of volcanic dust and gases on the atmosphere, weather, and climate.

Clearly the destructive potential of volcanoes is tremendous. But the risk to people living nearby can be reduced significantly by assessing volcanic hazards, monitoring volcanic activity and forecasting eruptions, and instituting procedures for evacuating populations. In addition, volcanism affects humankind in beneficial ways. Volcanism provides beautiful scenery, fertile soils, valuable mineral deposits, and geothermal energy. Over geologic time, volcanoes recycle the Earth's hydrosphere and atmosphere.

For coverage of related topics in the *Macropædia* and *Micropædia*, see the *Propædia*, sections 212 and 231.

This article is divided into the following sections:

Volcanic eruptions

LAVA, GAS, AND OTHER HAZARDS

The list of hazards associated with volcanic eruptions is long and varied: lava flows, explosions, toxic gas clouds, ash falls, pyroclastic flows, avalanches, tsunamis, and mud-flows. In addition to these immediate dangers, volcanic activity produces secondary effects such as property damage, crop loss, and perhaps changes to weather and climate. These hazards and long-term effects are described in this section.

Lava flows. The root zone of volcanoes is found some 70 to 200 kilometres (40 to 120 miles) below the surface of the Earth. There, in the Earth's upper mantle, temperatures are high enough to melt rock and form magma. At these depths, magma is generally less dense than the solid rocks surrounding and overlying it, and so it rises toward the surface by the buoyant force of gravity. In some cases, as in the undersea zones where the tectonic plates of the Earth's crust are separating, magma may move directly up to the surface through fissures that reach as deep as the mantle. In other cases, it collects in large underground reservoirs known as magma chambers before erupting to the surface. Molten rock that reaches the surface is called lava.

Most magma formed by partial melting of the mantle is basaltic in composition, but, as it ascends, it assimilates silica, sodium, and potassium from the surrounding host rocks. Volcanic rocks found where magma erupts to the surface are classified into four major types, or "clans"—basalt, andesite, dacite, and rhyolite. These rocks are ranked, as can be seen in Table 2, mainly by their silica content, which ranges from approximately 50 percent for basalt to approximately 75 percent for rhyolite. As silica content increases, rock types generally become more viscous.

If the vast, unseen undersea lava flows of the oceanic ridge system are considered, lava flows are the most common products of the Earth's volcanoes. There are two major types of lava flow, referred to around the world by

Magma chambers (margin note)

J D Griggs/U S Geological Survey

Figure 1: Basaltic lava erupts from the Pu'u 'O'o spatter and cinder cone on Kilauea volcano, Hawaii.

Figure 2: A cloud of ash and pumice rises into the air following an explosive eruption of Mount St. Helens, Washington state, U.S., on July 22, 1980.
Mike Doukas/U.S Geological Society

their Hawaiian names: pahoehoe, a more fluid flow with a smooth to ropy surface; and aa (or a'a), a more viscous flow whose surface is covered by thick, jumbled piles of loose, sharp blocks. Both types have the same chemical composition; the difference seems to be in the eruptive temperature and the speed of movement of the flow. As much as 99 percent of the island of Hawaii is composed of aa and pahoehoe flows. Indeed, Kilauea volcano has erupted continuously since 1983, its lava flows covering more than 100 square kilometres (40 square miles) of land and adding more than 2 square kilometres to the island where the lava has poured into the ocean. In the Mediterranean region, Mount Etna has issued lava more than 150 times since its first recorded activity in 1500 BC.

Pahaehoe and aa (margin note)

Explosions. Massive volcanic explosions are caused by the rapid expansion of gases, which in turn can be triggered by the sudden depressurization of a shallow hydrothermal system or gas-charged magma body or by the rapid mixing of magma with groundwater. The ash, cinders, hot fragments, and bombs thrown out in these explosions are the major products observed in volcanic eruptions around the world. These solid products are classified by size. Volcanic dust is the finest, usually about the consistency of flour. Volcanic ash is also fine but more gritty, with particles up to the size of grains of rice. Cinders, sometimes called scoriae, are the next in size; these coarse fragments can range from 2 millimetres (0.08 inch) up to about 64 millimetres (2.5 inches). Fragments larger than 64 millimetres are called either blocks or bombs. Volcanic blocks are usually older rock broken by the explosive opening of a new vent. Large blocks ejected in such explosions have been hurled as far as 20 kilometres from the vent. Volcanic bombs, in contrast, are generally incandescent and soft during their flight. Some bombs take on strange, twisted shapes as they

spin through the air. Others have a cracked and separated crust that has cooled and hardened in flight; they are called "breadcrust bombs."

A directed blast in which one side of a volcanic cone fails, as happened at Mount St. Helens in the United States in 1980, can cause destruction over several hundred square kilometres on the failed flank of the volcano. This is especially true if the blast cloud is heavily laden with fragmental debris and becomes dense and fluidized. It then takes on characteristics similar to a pyroclastic flow.

Pyroclastic flows.   Pyroclastic flows are the most dangerous and destructive aspect of explosive volcanism. Variously called *nuées ardentes* ("glowing clouds"), glowing avalanches, or ash flows, they occur in many sizes and types, but their common characteristic is a fluidized emulsion of volcanic particles, eruption gases, and entrapped air, resulting in a flow of sufficiently low viscosity to be very mobile and of sufficiently high density to hug the ground surface. A pyroclastic flow can pour over the lip of an erupting vent, or it may form when an ash column becomes too dense to continue rising and falls back to the ground. In major caldera collapses associated with explosive volcanoes (see below *Calderas*), huge pyroclastic flows may issue from the ring fractures as the caldera block subsides.

Pyroclastic flows can move at speeds up to 160 kilometres per hour and have temperatures ranging from 100 to 700° C (212 to 1,300° F). They sweep away and incinerate nearly everything in their path. Smaller pyroclastic flows are often confined to valleys. Large pyroclastic flows may spread out as a blanket deposit across many hundreds or even thousands of square kilometres around a major caldera collapse. During the past two million years, the area around Yellowstone National Park in the western United States has undergone three major caldera collapses involving pyroclastic eruptions of 280 to 2,500 cubic kilometres (67 to 600 cubic miles) of ash flows and ash falls.

Gas clouds.   Even beyond the limit of explosive destruction, the hot, ash-laden gas clouds associated with an explosive eruption can scorch vegetation and kill animals and people by suffocation. Gas clouds emitted from fumaroles (volcanic gas vents) or from the sudden overturn of a crater lake may contain suffocating or poisonous gases such as carbon dioxide, carbon monoxide, hydrogen sulfide, and sulfur dioxide. At Lake Nyos, a crater lake in Cameroon, West Africa, more than 1,700 people were killed by a sudden release of carbon dioxide in August 1986. Scientists theorize that carbon dioxide of volcanic origin had been seeping into the lake, perhaps for centuries, and had accumulated in its deep layers. It is thought that some disturbance, such as a large landslide into the lake, could have triggered the outburst of gas, creating an effervescence that stirred the lake and started the degassing.

The most common volcanic gases are water vapour, carbon dioxide, sulfur dioxide, and hydrogen sulfide. Small quantities of other volatile elements and compounds also are present, such as hydrogen, helium, nitrogen, hydrogen chloride, hydrogen fluoride, and mercury. The specific gaseous compounds released from magma depend on the temperature, pressure, and overall composition of the volatile elements present. The amount of available oxygen is of critical importance in determining which volatile gases are present. When oxygen is lacking, methane, hydrogen, and hydrogen sulfide are chemically stable, but when hot volcanic gases mix with atmospheric gases, water vapour, carbon dioxide, and sulfur dioxide are stable.

Some volcanic gases are less soluble in magma than others and therefore separate at higher pressures. Studies at Kilauea in Hawaii indicate that carbon dioxide begins to separate from its parent magma at depths of about 40 kilometres, whereas most of the sulfur gases and water are not released until the magma has nearly reached the surface. Fumaroles near Halemaumau Crater at Kilauea's summit are rich in carbon dioxide that leaks from the magma chamber located 3 to 4 kilometres beneath the surface. Fumaroles on the rift zones of Kilauea, however, are richer in water vapour and sulfur because much of the carbon dioxide leaks away at the summit before the magma is intruded into the rift zones.

Ash falls.   Ash falls from continued explosive jetting of fine volcanic particles into high ash clouds generally do not cause any direct fatalities. However, where the ash accumulates more than a few centimetres, collapsing roofs and failure of crops are major secondary hazards. Crop failure can occur over large areas downwind from major ash eruptions, and widespread famine and disease may result, especially in poorly developed countries. In the long run, however, the decomposition of nutrient-rich volcanic fallout is responsible for some of the world's best soils.

Avalanches, tsunamis, and mudflows.   Avalanches of rock and ice also are common on active volcanoes. They may occur with or without an eruption. Those without an eruption are often triggered by earthquakes, by weakening of rock into clay by hydrothermal activity, or by heavy rainfall or snowfall. Those associated with eruptions are sometimes caused by oversteepening of a volcano's flank by intrusion of a shallow body of magma within or just beneath the volcanic cone, as happened at Mount St. Helens.

A caldera collapse that is in part or entirely submarine usually generates a tsunami. The larger and more rapid the collapse, the larger the tsunami. Tsunamis also can be caused by avalanches or large pyroclastic flows rapidly entering the sea on the flank of a volcano.

Mudflows, or lahars, are common hazards associated with stratovolcanoes and can happen even without an eruption.

Nuées
ardentes

Mudflows

Figure 3: Buildings and vegetation at Clark Air Base, Philippines, are destroyed by a thick, wet layer of ash following the gigantic explosion of Mount Pinatubo on June 15, 1991.

Figure 4: A young woman is rescued from a mudflow that buried the town of Armero, Colombia, following the eruption of Mount Ruiz on Nov. 13, 1985.
AP

They occur whenever floods of water mixed with ash, loose soil, or hydrothermal clay sweep down valleys that drain the sides of large stratovolcanoes. The huge mudflows generated by meltwater from the ice cap of Mount Ruiz, Colombia, in 1985 are classic examples of mudflows associated with eruptions. Heavy rainfall or earthquake-induced avalanches of ice or hydrothermal clay also can cause mudflows on steep volcanoes during periods of repose between eruptions.

Economic damage

Secondary damage. Property damage from volcanic eruptions is difficult to estimate because of differing value systems and changes in land use. One study estimates an average of $1 billion per year in property damage worldwide from volcanic eruptions. As with casualties, a few eruptions cause staggering damage, while most are much less destructive. The Mount St. Helens eruption in 1980 caused more than $1 billion worth of damage, mainly to the timber industry. The economic cost of the 1991 eruption of Mount Pinatubo in the Philippines was estimated at $7 billion, though it is likely that losses continued to mount for years afterward because of the inundation of much arable land by mudflows.

A new danger that has emerged with the increase in air travel is the serious threat posed to jet aircraft by high clouds of volcanic ash and aerosols. These clouds cannot be detected by weather radar, and they are difficult for pilots to distinguish from meteorological clouds. In a small number of documented cases, jet engines have stopped operating after airliners have flown through volcanic clouds. Catastrophe was avoided only at the last minute when the pilots were able to restart the engines as their planes descended below the clouds. The engines had to be replaced and major abrasive damage to the planes repaired. During the Pinatubo eruption, aircraft had 16 damaging encounters with ash clouds, one as far away as 1,700 kilometres west of the volcano. In response to these hazards, a worldwide system has been established to alert pilots by radio of volcanic eruption clouds and their probable extent.

Long-term environmental effects. Not all volcanic phenomena are destructive. The oceans, atmosphere, and continents owe their origin and evolution in large measure to volcanic processes throughout geologic time. A lava flow may engulf and bury the land, but new soil and vegetation eventually develop. In warm, humid climates the recovery is rapid; a few decades will suffice to hide the rocky surface of solidified lava flows. In desert or Arctic climates, on the other hand, recovery is slower; flows more than 1,000 years old may still retain their barren appearance. Volcanic ash slowly weathers to form rich, loamy soils. On the volcanic island of Java, terraced rice paddies support a dense population. Across the Java Sea is Borneo, an island with a similar climate but no volcanoes. The jungles of Borneo provide only temporary slash-and-burn agriculture and therefore support a much smaller population.

Effects on climate

Climate, too, is subject to the effects of volcanic activity. High ash clouds, especially if they are rich in sulfur dioxide, can inject much fine dust and aerosol droplets of sulfuric acid into the stratosphere, above tropospheric rain clouds. Their height greatly increases the residence time of these fine particles in the atmosphere—they are not washed quickly back to Earth but spread slowly into haze layers that can blanket a hemisphere or even the entire Earth.

World climate seems to have been affected by the eruptions of Krakatoa (Krakatau) near Java in 1883, Mount Agung in Bali in 1963, and Pinatubo in 1991. The high ash clouds thrown up by these volcanoes apparently lowered average world temperature by about $0.5°$ C $(0.9°$ F) over one to three years following their eruptions. Although world temperature data was poorly recorded in the early 1800s, the eruption of Mount Tambora on the island of Sumbawa in 1815 was followed in 1816 in North America and Europe by what was called "the year without a summer." On the other hand, other large eruptions, such as that of Novarupta near Mount Katmai in Alaska in 1912, appear to have produced no cooling effect. Records of average world temperature over the past several decades often show changes of 0.1 to $0.3°$ C (0.2 to $0.5°$ F) from year to year unrelated to any known volcanic eruptions, so it is difficult to establish with certainty whether volcanoes have a major impact on climate.

Direct sampling of the stratosphere has shown that the major haze-forming agent from volcanic eruptions is not fine dust but an aerosol of tiny sulfuric acid droplets. This indicates that the composition of high volcanic ash clouds may be as important as their volume in affecting climate. Atmospheric chemists are interested in atmospheric perturbations that may be caused not only by volcanic eruptions but also by man-made aerosols of chlorofluorocarbons, exhaust from high-altitude jet aircraft, and a general increase in carbon dioxide and other greenhouse gases from the burning of fossil fuels. The Earth has many buffers that maintain its environment, but their interactions are not clearly understood. Many questions as to how volcanic and human activity affect climate remain largely unanswered, and they are important problems of ongoing research.

SIX TYPES OF ERUPTIONS

Volcanoes are frequently classified by their size and shape (as is described below in *Volcanic landforms*), but they can also be classified by their eruptive habits. Indeed, the type of volcanic eruption that occurs plays an important role in the evolution of a volcanic landform, thus forming a significant link between eruptive habit and volcanic structure. In general, eruptions can be categorized as either effusive or explosive. Effusive eruptions involve the outpouring of basaltic magma that is relatively low in viscosity and in gas content. Explosive eruptions generally involve magma that is more viscous and has a higher gas content. Such magma is often shattered into pyroclastic fragments by explosive gas expansion during an eruption.

Effusive and explosive eruptions

In more-detailed classification schemes based on character of eruption, volcanic activity and volcanic areas are commonly divided into six major types, shown schematically in Figure 5. In order of increasing degree of explosiveness, they are: (1) Icelandic, (2) Hawaiian, (3) Strombolian, (4) Vulcanian, (5) Pelean, and (6) Plinian.

The Icelandic type is characterized by effusions of molten basaltic lava that flow from long, parallel fissures. Such outpourings often build lava plateaus.

The Hawaiian type is similar to the Icelandic variety. In this case, however, fluid lava flows from a volcano's summit and radial fissures to form shield volcanoes, which are quite large and have gentle slopes.

Strombolian eruptions involve moderate bursts of expanding gases that eject clots of incandescent lava in cyclical or nearly continuous small eruptions. Because of such small frequent outbursts, Stromboli volcano, located on Stromboli Island off the northeast coast of Italy, has been called the "lighthouse of the Mediterranean."

Figure 5: The major types of volcanic eruptions.
Encyclopædia Britannica, Inc

The Vulcanian type, named for Vulcano Island near Stromboli, generally involves moderate explosions of gas laden with volcanic ash. This mixture forms dark, turbulent eruption clouds that rapidly ascend and expand in convoluted shapes.

A Pelean eruption is associated with explosive outbursts that generate pyroclastic flows, dense mixtures of hot volcanic fragments and gas described above in *Lava, gas, and other hazards*. Pelean eruptions are named for the destructive eruption of Mount Pelée on the Caribbean island of Martinique in 1902. The fluidized slurries produced by these eruptions are heavier than air but are of low viscosity and pour down valleys and slopes at great velocities. As a result, they are extremely destructive.

Plinian
eruptian of
Mount
Vesuvius

The Plinian type is an intensely violent kind of volcanic eruption exemplified by the outburst of Mount Vesuvius in Italy in AD 79 that killed the famous Roman scholar Pliny the Elder and that was described in an eyewitness account by the historian Pliny the Younger, his nephew. In this type of eruption, gases boiling out of gas-rich magma generate enormous and nearly continuous jetting blasts that core out the magma conduit and rip it apart. The uprushing gases and volcanic fragments resemble a gigantic rocket blast directed vertically upward. Plinian eruption clouds can rise into the stratosphere and are sometimes continuously produced for several hours. Lightning strikes caused by a buildup of static electricity are common close to Plinian ash clouds, adding one more element of terror to the eruption.

Why are some volcanic eruptions so explosive while others are so spectacular but relatively harmless? The answer involves at least four factors: the amount of gas dissolved in the magma, the viscosity of the magma, the rate of decompression of the magma as it rises toward the surface, and the number of nucleation sites on which the gases can begin to form bubbles. Volcanoes related to converging plate margins (see below *Volcanism and tectonic activity*) generally have a high gas content, and their magma is very viscous. This combination is explosive because the gases cannot easily boil out; rather, they remain pent up until they reach the pressure at which they blow the viscous magma into fragments. The rate at which pressure is reduced also controls the explosiveness. If magma moves slowly toward the surface, its dissolved gases will be released slowly and can escape. During the 1991 Plinian-type eruption of Mount Pinatubo, magma moved quite rapidly toward the surface, resulting in retention of most of the dissolved gases. Finally, the speed at which gases are released from magma is affected by the number of small crystals, which can act as nucleation sites where gas bubbles begin to form. At Pinatubo the magma was more than 40 percent small crystals before the eruption, while at the Hawaiian volcanoes Kilauea and Mauna Loa the percentage of small crystals in the magma is very low (less than 5 percent).

TWO 20TH-CENTURY ERUPTIONS

There are many gradations among—and exceptions to—the idealized eruption types listed in the previous section, and it is not unusual for an eruption sequence to involve more than one type of activity. For example, the eruptions of Mount St. Helens from 1980 to 1986 followed a sequence of small Vulcanian-type explosions, large Pelean and Plinian explosions, and finally extrusions of viscous lava into a lava dome that capped the vent. The different types of volcanic activity can best be understood by making comparisons, and in this section two specific eruptions are compared—the 1991 eruption of Mount Pinatubo (a classic example of explosive volcanism) and the 1984 eruption of Mauna Loa (illustrative of effusive volcanism).

Mount Pinatubo, Philippines, 1991. Earthquakes and steam explosions announced the reawakening of Mount Pinatubo in 1991, surprising many geologists because Pinatubo was not even listed in catalogs of world volcanoes. This mountain (at that time having an elevation of 1,745 metres, or 5,725 feet) lacked the classic conical shape of a volcano because erosion had carved its summit into a ragged ridge with steep jungle-covered slopes, and there was no written record of any eruptions. Nevertheless, scientists at the Philippine Institute of Volcanology and Seismology (PHIVOLCS) took the awakening of Pinatubo

The
awakening
of Mount
Pinatubo

very seriously, knowing that the longer the repose between eruptions, the more dangerous a volcano may be. The area surrounding the volcano included densely populated regions. Clark Air Base, a major U.S. Air Force base in the Philippines, also abutted the volcano.

The eruption developed in several stages. On March 15, 1991, a swarm of small, locally discernible earthquakes began on the northwest side of Pinatubo. On April 2, steam explosions opened up three large steam and sulfurgas vents, or fumaroles, along a fissure 3 kilometres (1.9 mile) in length located high on the north flank of the volcano. Evacuation of residents living within a 10-kilometre (6-mile) radius of the summit was recommended. Through April and May, a network of seismometers set up by PHIVOLCS recorded between 30 and 180 small earthquakes per day. In late April the seismic network was expanded in conjunction with the U.S. Geological Survey to provide better determination of the ongoing earthquakes' epicentres and depths. Airborne measurements of sulfur dioxide (SO_2) gas from the fumaroles were started on May 13, and the measurements showed the SO_2 emissions increasing from 500 metric tons per day to more than 5,000 tons per day by May 28.

On June 1 a new swarm of earthquakes began at shallow depths about 1 kilometre northwest of the summit, indicating that magma was creating fractures as it forced open a conduit toward the surface from the magma chamber beneath the volcano. On June 3 a small explosion signaled the beginning of a new stage of activity. Minor, intermittent eruptions of ash began at the summit area, and a tiltmeter high on the volcano's east side began to lean outward. On June 7 an eruption of steam and ash reached a height of 7 to 8 kilometres, and the next morning an observer in a helicopter confirmed that magma had indeed reached the surface. From June 8 to June 12, ash eruptions and shallow earthquakes increased. The alert level was raised to "eruption in progress," and the evacuation radius was extended to 20 kilometres from the summit. About 25,000 residents left, and Clark Air Base evacuated 14,500 people.

The first major explosive eruption occurred the morning of June 12; it lasted about an hour and generated a column of volcanic gas and ash 20 kilometres high. The danger radius was increased to 30 kilometres and the total number of evacuees increased to about 60,000 people. Another major explosion occurred during the night on June 12, followed by five more over the next two days. The character of the eruptions changed on June 14, with increasing production of pyroclastic flows. Observation of the volcano was greatly hindered by the arrival of a major typhoon on June 15. Ten closely spaced explosive eruptions occurred during the night and morning of that day, but little could be seen.

The climactic eruption began in the early afternoon of June 15. Visible observations were impossible because of winds and rain brought by the typhoon, but seismograph, barograph, and satellite observations recorded the second largest eruption of the 20th century—exceeded only by the giant 1912 eruption of Novarupta near Mount Katmai in Alaska. The huge Plinian-type eruption of Pinatubo lasted about nine hours. By mid-afternoon, conditions around the volcano included pitch darkness, falling ash and pumice lumps as large as 4 centimetres (1.6 inches) in diameter, high winds and heavy rain, lightning flashes, and earthquakes. Major ground tremors were felt about every 10 to 15 minutes. Satellite images showed that a giant, umbrella-shaped eruption cloud had formed that was 400 kilometres in diameter and 34 kilometres high at its apex. The ash fall from this cloud covered an area of 7,500 square kilometres (2,900 square miles) to a depth of 1 centimetre (0.4 inch) or more with wet, gray ash and pumice; the maximum thickness was about 50 centimetres a few kilometres southwest of the vent area. The volume of ash was about 5 cubic kilometres (1.2 cubic miles). Most of the 300 deaths caused directly by the eruption were the result of roofs and buildings collapsing from the weight of wet ash.

During the giant eruption, huge pyroclastic flows—mixtures of hot ash and gases denser than air—swept down the flanks of Pinatubo as far as 16 kilometres from its old summit. These intensely hot ash flows sterilized 400 square kilometres of land around the volcano, filling valleys with high-temperature deposits as much as 200 metres (660 feet) thick. Floods from the typhoon rains churned up the loose volcanic ash and pyroclastic deposits and poured thick mudflows down all the streams and river valleys around the mountain. For years after the eruption, as heavy rainfall and flooding eroded the thick pyroclastic deposits, recurring mudflows buried towns and farm fields, destroyed roads and bridges, and displaced more than 100,000 people.

An estimated 17 million tons of SO_2 gas were injected into the stratosphere by Pinatubo's high eruption cloud. This formed an aerosol of tiny sulfate droplets that, with the extremely fine volcanic dust, circled the globe in about three weeks and reduced solar radiation reaching the Earth's surface. This stratospheric haze layer diminished during the next three years and apparently caused an average cooling of 0.4° C (0.7° F) of the Earth's climate during 1992–93.

Mauna Loa, Hawaii, 1984. On average, Mauna Loa, located on the island of Hawaii in the Pacific Ocean, erupts

The climactic eruption of Mount Pinatubo

David H. Harlow/U.S. Geological Survey

Figure 6: A column of gas and ash rises from Mount Pinatubo, Philippines, on June 12, 1991, just days before the volcano's climactic explosion on June 15.

every three and a half years with fountains and streams of incandescent lava. Following a year of increased seismicity, Mauna Loa began erupting at 1:25 AM on March 25, 1984. The outbreak began along a fissure that split the long axis of the summit caldera, an oval, cliff-bounded basin approximately 3 to 5 kilometres (1.9 to 3.1 miles) from rim to rim that had been formed by prehistoric subsidence. Lava fountains along the fissure formed a curtain of fire that illuminated the clouds and volcanic fumes into a red glow backlighting the black profile of the volcano's huge but gently sloping summit. Lava from the summit fissure ponded in the caldera, and the first observers in the air reported that much of the caldera floor was covered by a lake of orange-red molten rock, which quickly cooled to a black crust with zigzag-shaped fractures that were still incandescent.

Katia Krafft

Figure 7: A curtain of fire is formed by a line of lava fountains on the northeast rift zone of Mauna Loa volcano, Hawaii, on March 25, 1984.

At dawn the summit fissure began to propagate down the northeast rift zone, and a new line of lava fountains formed at an elevation of 3,800 metres (12,500 feet). Two hours later the fracture extended an additional 6 kilometres down the northeast rift, forming another curtain of fire about 2 kilometres long and 50 metres high at an elevation of 3,450 metres. As new vents opened at lower elevations, the higher vents stopped erupting. The vents at 3,450 metres continued to erupt throughout the early afternoon, sending a small lava flow down the high southeast flank of Mauna Loa. At about 4:00 PM the lava fountains dwindled, and a swarm of new earthquakes indicated that the fissure was propagating even farther down the rift. It stopped opening some 7 kilometres down the ridge at an elevation of 2,900 metres, where new and final vents opened at 4:40 PM.

The output of lava from these final vents was vigorous. Although the fountains were only about 20 metres high, the volume of lava produced amounted to approximately 500,000 cubic metres (about 17.6 million cubic feet) per hour. In 24 hours the river of lava flowed 12 kilometres northeast toward the city of Hilo. The vents erupted steadily for the next 10 days. Even though the eruption rate remained high, the advance of the front of the lava flow slowed, traveling 6 kilometres on the second day, 4 kilometres on the third day, and 3 kilometres on the fourth day. This progressive slowing of the lava front had several causes. The lava supply was increasingly starved at lower altitudes by a slow widening of flows at higher elevations, by thickening of flows at higher elevations through overplating (that is, accumulation of new layers on top of layers only a few hours or days old), and by branching of the flows upstream into new lobes that robbed the lower flows of their lava. An additional cause was the thickening and widening of flows at lower elevations where the slope of the land is more gradual.

By April 5, output from the vents at 2,900 metres had begun to wane, and the eruption was over by April 15. The longest flows had traveled 27 kilometres, stopping at an el-

evation of 900 metres—10 kilometres from the outskirts of Hilo. The total volume of the eruption was 220 million cubic metres, and new lava flows covered 48 square kilometres (18.5 square miles). No one was hurt, and the only significant damage was the cutting of power lines and the blocking of a few jeep roads.

The temperature of the erupting lava was 1,140° C (2,084° F) and its viscosity was about 10^3 poise (dyne-seconds per cm²), which is roughly equivalent to the viscosity of liquid honey at 20° C (68° F). A household analog of a Hawaiian lava flow in miniature is the slow and erratic advance of molten wax as it adds new lobes to a pile of candle drippings.

Mauna Loa's massive outpourings of lava have made it the world's largest volcano. Its summit rises 4,170 metres above sea level and more than 9,000 metres above the seafloor surrounding the Hawaiian Ridge. The volume above its base, which has subsided well below the adjacent seafloor, is estimated to be about 75,000 cubic kilometres.

Kilauea, a smaller and younger volcano on the southeast side of Mauna Loa, has been erupting lava from 1983 to the present. Its output of lava has averaged about 400,000 cubic metres per day, in sharp contrast to the 12 million cubic metres per day during the first week of the 1984 eruption of Mauna Loa. It is this slow but steady effusion of molten lava that has allowed the eruption of Kilauea to continue so long. Apparently, magma from depth is replacing the amount being erupted at a balanced rate. In contrast, the effusion of lava at Mauna Loa in 1984 was at a much more rapid rate than that at which magma could be resupplied from depth, and the eruption was soon exhausted. Both Mauna Loa and Kilauea were erupting at the same time in 1984. Even though the difference in elevation between the vents on Mauna Loa and Kilauea was only 2,000 metres, there was no apparent effect of one eruption upon the other. This indicates that, although both volcanoes have the same general source region of magma about 60 kilometres below the surface, their conduits and shallower magma chambers are separate.

The continuous eruption of Kilauea

FOUR WORST ERUPTIONS IN HISTORY

Since the late 1700s, volcanoes have caused more than 250,000 deaths. Most of these occurred during four disastrous eruptions.

The largest of the four occurred on April 10–11, 1815, at Mount Tambora on Sumbawa Island, now a part of Indonesia. Fifty cubic kilometres (12 cubic miles) of magma were expelled in Plinian ash clouds and pyroclastic flows. Ash layers greater than 1 centimetre (0.4 inch) thick fell on more than 500,000 square kilometres (193,000 square miles) of Indonesia and the Java Sea. Before the eruption Tambora was a stratovolcano some 4,300 metres (14,100 feet) high; following the eruption, approximately 1,400 metres of the summit cone were missing, and in its place was a collapsed caldera 6 by 7 kilometres (3.7 by 4.4 miles) wide and 1 kilometre deep. About 10,000 people were killed by the explosive eruption and the tsunamis caused by massive pyroclastic flows entering the sea. Agricultural losses from the thick ash deposits resulted in famine and disease, leading to an additional 82,000 deaths.

The second largest eruption of the 19th century also occurred in Indonesia. Krakatoa (Krakatau), a composite volcano on a small uninhabited island between Sumatra and Java, erupted explosively on Aug. 26–27, 1883. The eruption was similar to the Tambora outburst but smaller, involving about 18 cubic kilometres of magma erupted in Plinian ash clouds and pyroclastic flows. Krakatoa was a smaller volcano than Tambora, and, when the eruption had emptied part of its magma chamber, it collapsed to form a caldera that was partly below sea level. Twenty-three square kilometres of the island disappeared, and where a volcanic peak 450 metres high once stood was water as deep as 275 metres. The largest explosion on the morning of August 27 produced an ash cloud that was reported to have reached a height of 80 kilometres, and the detonation was heard as far away as Australia. A tsunami over 30 metres high followed the explosion and apparent caldera collapse, killing about 36,000 people on the adjacent shores of Java and Sumatra.

Krakatoa (Krakatau)

Figure 8: Colour lithograph of the eruption of Krakatoa (Krakatau) volcano, Indonesia, 1883; from the Royal Society, *The eruption of Krakatoa and subsequent phenomena* (1888).
Hulton Archive/Getty Images

On May 8, 1902, there occurred a violent eruption of Mount Pelée, a stratovolcano on the island of Martinique in the Caribbean Sea. Although less than 1 cubic kilometre of magma was erupted, much of it formed a high-velocity pyroclastic flow that swept down a steep valley to the port of Saint-Pierre. Within minutes the town and virtually all of its inhabitants (some 29,000 people) were incinerated.

The second worst volcanic disaster of the 20th century occurred on Nov. 13, 1985, when a relatively small eruption of Mount Ruiz, a stratovolcano in the Andes Mountains of Colombia, killed 25,000 people. This volcano is tall enough, at an elevation of 5,400 metres, to have a glacial ice cap. When a brief explosive eruption dumped several million cubic metres of hot pyroclastic fragments onto the ice surrounding the summit crater, a sudden

Figure 9: A cloud of hot volcanic gas and particles sweeps down the slope of Mount Pelée toward the port of Saint-Pierre, Martinique, on May 8, 1902.

surge of meltwater sent massive mudflows down canyons on both the east and west sides of the volcano. Much of the town of Armero, built on a low plain beside the Lagunilla River 50 kilometres east of and nearly 5 kilometres in elevation below the summit of Mount Ruiz, was buried by the mudflows. Twenty-two thousand of its inhabitants were killed.

About 70 percent of the people who died from volcanic eruptions in the past 200 years perished in those four outbursts. The remaining 30 percent were killed in many other less-devastating eruptions. As world population increases, however, so does the risk of greater loss of life from volcanic eruptions. This was made all too clear by the tragedy at Armero. In 1845 a mudflow from Mount Ruiz killed approximately 1,000 people on farms near the site where the town of Armero was later built. In the 1985 mudflow, which was smaller in volume than the 1845 mudflow, more than 20 times as many people were killed.

VOLCANO FORECASTING AND WARNING

The greatest hazard at potentially active volcanoes is human complacency. The physical hazards can be reliably estimated by studying past eruptive activity as recorded in history or in the prehistoric deposits around a volcano. Volcano observatories can monitor local earthquake activity and the surface deformation of a potentially active volcano and make useful, if not yet precise, forecasts of eruptions. For instance, the measurement of increased earthquake activity beneath Mauna Loa in 1983 led to a *Measuring seismic activity and surface deformation*

Encyclopædia Britannica, Inc
Figure 10: *Profiles of volcanic landforms.*
Vertical dimensions are exaggerated, and relative sizes are approximate.

forecast of an increase in probability of an eruption for 1984 or 1985; an eruption occurred in March 1984. The major eruption of Mount St. Helens on May 18, 1980, was much larger than anticipated, but a high number of local earthquakes and a visible bulge forming on the north flank of the mountain provided enough warning to encourage a partial evacuation of the surrounding area. Lives were lost, but the toll would have been much higher if access to the

Figure 11: Mayon Volcano, Luzon, Philippines, shows the classic symmetrical cone shape of a stratovolcano.
Stephen and Donna O'Meara/Photo Researchers

area had not been restricted by local authorities. A major problem in reducing volcanic risk is that most explosive volcanoes have such long repose periods that people living nearby consider them extinct rather than dormant.

The correct forecast and evacuation of residents before the 1991 eruption of Mount Pinatubo saved thousands of lives, but the science of eruption forecasting is only beginning and is still fraught with uncertainty. Evacuation of large numbers of people is difficult and expensive. A major evacuation not followed by any major eruption would be a serious mistake, but not evacuating people from a threatening volcano that then erupts catastrophically would be a much worse mistake. It is not a simple problem.

Volcanic landforms

MAJOR TYPES

The common mental image of a volcano is that of a steep symmetrical cone sweeping upward in a concave curve to a sharp summit peak. Mount Fuji in Japan is the archetype of this image, but in reality only a few volcanoes attain this ideal shape. Each of the more than 1,500 potentially active volcanoes or volcanic areas around the world has a distinct

Table 1: Most common volcano types of the world

volcano types	number	prominent examples
stratovolcanoes	734	Fuji (Honshu, Japan), Pinatubo (Luzon, Philippines), St. Helens (Washington, U.S.), Cotopaxi (Ecuador), Etna (Sicily, Italy), Ol Doinyo Lengai (Tanzania)
shield volcanoes	171	Fournaise (Réunion), Kilauea (Hawaii, U.S.), Nyamulagira (Congo [Kinshasa]), Tolbachik (Kamchatka, Russia), Tristan da Cunha (South Atlantic)
pyroclastic cones	138	Cerro Negro (Nicaragua), Parícutin (Michoacán, Mexico), Craters of the Moon (Idaho, U.S.)
submarine volcanoes	110	Loihi (Hawaii, U.S.), Vestmanna Islands (Iceland)

form, though most can be generalized into nine categories (see Table 1). These categories are described below in order of their numerical importance.

Stratovolcanoes. Stratovolcanoes such as Mayon Volcano in the Philippines, Mount Momotombo in Nicaragua, and Ol Doinyo Lengai in Tanzania are steep cones built by both pyroclastic and lava-flow eruptions. The cone-shaped form slopes up gradually and becomes steeper (up to 35°) toward the summit, which generally contains a crater. Stratovolcanoes are composed of volcanic rock types that vary from basalt to rhyolite, but composition is generally andesite. They may erupt many thousands of times over life spans of millions of years. A typical eruption begins with ash explosions and ends with extrusion of thick, viscous lava flows. The alternating layers (strata) of ash and lava are not continuous, blanketlike deposits; rather, they are overlapping lobes or tongues of ash and lava. For this reason many geologists refer to stratovolcanoes as composite volcanoes.

Layers of ash and lava

Shield volcanoes. Structures of this type are large, dome-shaped mountains built of lava flows. Their name derives from their similarity in shape to a warrior's shield lying face up. Shield volcanoes are usually composed of basalt. Small shield volcanoes may form rapidly from almost continuous eruptions, but the larger shields are formed over a span of about 1 million years by hundreds of thousands of effusive eruptions of fluid lavas from their summits and rift zones. The slopes of shield volcanoes are gentle, seldom exceeding 6°. The summits, which are nearly flat, are generally indented by cliff-walled craters or calderas. The Hawaiian volcano Mauna Loa is a typical shield volcano. Its elongate shape records a long history of fluid lava flows not only from its summit but from its two persistent rift zones.

Submarine volcanoes. These structures occur in various forms, but many are cone-shaped seamounts. Some ancient island volcanoes were eroded flat or covered with a coral cap at sea level before they sank below the sea surface as they and the crust supporting them cooled and became denser. These flat-topped seamounts are called guyots. Most of the active submarine volcanoes that are known occur at shallow depths beneath the sea. They are recognized because their explosive eruptions can be detected and located by hydrophones. Active submarine volcanoes at depths of a few thousand metres are probably common, particularly along oceanic spreading centres, but the water pressure at these depths reduces explosive boiling, and so the eruptions are difficult to detect. One exception to this is the submarine volcano Loihi, a seamount whose summit caldera is 1 kilometre (0.6 mile) below sea level and 30 kilometres southeast of the island of Hawaii. Although

Figure 12: Computer-generated image of the summit area of Loihi, a submarine volcano southeast of the island of Hawaii. Loihi shares the same "hot spot" on the Earth's crust that has formed Mauna Loa and Kilauea volcanoes on Hawaii.

eruptions of this youngest volcano of the Hawaiian chain have not been directly observed, seismographs detected swarms of earthquakes at shallow depths beneath the summit of Loihi in 1971–72, 1975, and 1996. Observers in a submersible research vessel from the University of Hawaii dove to Loihi as the 1996 earthquakes waned; they discovered a new collapse crater at the summit and fine white "dust" that greatly reduced visibility but saw no red lava or erupting vents. A submarine eruption has not yet been directly observed in progress.

Calderas. Most calderas—large circular or oval depressions more than 1 kilometre in diameter—have been formed by inward collapse of landforms after large amounts of magma have been expelled from underground. Many are surrounded by steep cliffs, and some are filled with lakes. The terms *crater* and *caldera* are often used synonymously, but calderas are larger than craters. A crater can occur inside a caldera, as at Taal Lake in the Philippines, but not the reverse. Calderas are often associated with large eruptions (those producing volumes of 10 cubic kilometres [2.4 cubic miles] or more) of dacitic or rhyolitic magma that form pyroclastic plateaus.

Calderas also occur on shield volcanoes. These calderas are thought to form when large rift eruptions or lateral intrusions remove tremendous quantities of magma from the shallow magma chambers beneath the summit, leaving the ground above the chambers with no support. The collapse and refilling of calderas on active Hawaiian volcanoes probably recur many times during a volcano's lifetime.

Whether a volcano is designated a caldera, shield volcano, or stratovolcano with a caldera depends on the principal landform feature. For example, Crater Lake in Oregon in the northwestern United States is designated a caldera, but Kilauea in Hawaii is designated a shield volcano even though it has a large summit caldera.

Complex volcanoes. Such structures are mixed landforms. In most cases, they occur because of changes either in eruptive habit or in location of the principal vent area. A stratovolcano may form a large explosion crater that later becomes filled by a lava dome, or several new cones and craters may develop on a caldera's rim. One stratovolcano may have multiple summits when individual cones overlap one another. The Three Sisters volcanic complex in Oregon is an example of a complex volcano with three summits.

Pyroclastic cones. Pyroclastic cones (also called cinder cones or scoria cones) such as Cerro Negro in Nicaragua are relatively small, steep (about 30°) volcanic landforms built of loose pyroclastic fragments, most of which are cinder-sized. The fragments cool sufficiently during their flight through the air so that they do not weld together when they strike one another. Generally, the crater from which the cinder fragments were ejected is located in the centre of the cone. In areas with strong prevailing winds, however, the crater may be upwind of the cone. The rock type involved in pyroclastic cones is generally basalt or basaltic andesite, and the eruption type is either the moderately explosive Vulcanian or the gentler Hawaiian, which produces high lava fountains.

Some cinder cones such as Parícutin in Mexico grow during a single eruption. Parícutin rises approximately 410 metres (1,345 feet) from its base to its summit and is 1 kilometre wide; it formed during nearly continuous eruptions from 1943 to 1952. Cinder cones also form at some vents on shield volcanoes, but these are not considered to be separate, individual volcanoes. Certain cinder cones have multiple eruptions, but, if activity continues for thousands to tens of thousands of years from the same vent, it is likely that they will develop into stratovolcanoes or complex volcanoes.

Pumice cones are structures similar to cinder cones, but they are made up of volcanic glass fragments so riddled with gas-bubble holes (vesicles) that they resemble a sponge and are very lightweight. Less common pyroclastic landforms include maars, low-relief craters often filled with water and surrounded by a rim of ejected material that was probably formed by explosive interaction of magma and groundwater; and tuff rings and tuff cones, which are land-

Cinder cone volcanoes

Figure 13: Volcano Island rises from Taal Lake, which fills a broad, shallow caldera created by the collapse of an ancient volcano, Luzon, Philippines.

Figure 14: Eruption of Cerro Negro volcano, Nicaragua, November 1969. Cerro Negro is a cinder cone type of volcano that was born of a series of eruptions beginning in 1850. It is still active and periodically blankets the surrounding countryside with ash.

U.S. Department of the Interior, Geological Survey

forms built of compacted pyroclastic deposits. Tuff rings and cones resemble maars, but they have higher rims and are not filled with water. Tuff rings are only about 5 metres high, with craters roughly at ground level. Tuff cones are higher and steeper, with craters above ground level. Punchbowl and Diamond Head on Oahu island, Hawaii, are famous examples of tuff cones.

Volcanic fields. Such areas have many geologically young cinder cones or other features that have not been individually identified as separate volcanoes. If the conduits through which magma ascends to the surface are scattered over a broad area, many short-lived volcanoes are formed rather than a major volcano with repeated eruptions. The area in which Parícutin formed is a volcanic field with dozens of prehistoric—but geologically young—cinder cones and lava flows. The most likely place for the birth of a new volcano is in a known volcanic field.

Fissure vents. These features constitute the surface trace of dikes (underground fractures filled with magma). Most dikes measure about 0.5 to 2 metres in width and several kilometres in length. The dikes that feed fissure vents reach the surface from depths of a few kilometres. Fissure vents are common in Iceland and along the radial rift zones of shield volcanoes.

Fissure vents and Iceland

In Iceland the volcanic vents often are long fissures parallel to the rift zone where lithospheric plates are diverging. Renewed eruptions generally occur from new parallel fractures offset by a few hundred to thousands of metres from the earlier fissures. This distribution of vents and voluminous eruptions of fluid basaltic lava usually build up a thick lava plateau rather than a single volcanic edifice. The largest effusive eruption of lava in recorded history occurred in 1783 in Iceland from the Laki fissure. This vent produced high lava fountains, a crater row 25 kilometres long, and 565 square kilometres (218 square miles) of basaltic lava flows with a volume of approximately 12 cubic kilometres.

The radial fissure vents of Hawaiian volcanoes produce "curtains of fire" as lava fountains erupt along a portion of a fissure. These vents produce low ramparts of basaltic spatter on both sides of the fissure. More isolated lava fountains along the fissure produce crater rows of small spatter and cinder cones. The fragments that form a spatter cone are hot and plastic enough to weld together, while the fragments that form a cinder cone remain separate because of their lower temperature.

Lava domes. Landforms of this sort consist of steep domal mounds of lava so viscous that the lava piles up over its vent without flowing away. The rock types that form lava domes are generally andesites, dacites, or rhyolites. Somehow these viscous lavas have lost much of their gas content in prior eruptions or during a slow rise to the surface.

Even so, it is not unusual for an actively growing lava dome to have an explosive eruption that disrupts all or part of the dome. Many lava domes grow by internal intrusion of lava that causes swelling and oversteepening of the dome. Rockslides build up an apron of talus blocks around the lower sides of the dome. Lava domes can form mounds several hundred metres high with diameters ranging from several hundred to more than 1,000 metres. Thick lava flows sometimes move short distances from the dome and distort its generally circular or oval shape. A good example of a lava dome is the one in the explosion crater at Mount St. Helens.

Other volcanic structures and features. There are many types of volcanic forms and terms other than those described above. Some general terms that may be encountered include *volcanic cone*, which is a descriptive term pertaining to shape with no implication of size, rock type, or genesis; and *explosion crater*, a large circular, elongate, or horseshoe-shaped excavation with ejected debris on its rim or flanks.

A somma volcano, named for Mount Somma, a ridge on the slopes of Mount Vesuvius in Italy, is a caldera partially filled by a new central cone. In some areas, magma or still-hot igneous rocks at shallow depth leak gases through gas vents or interact with the groundwater system to create hot springs. These areas are known as hydrothermal regions, fumarole fields, or solfatara fields.

DETERMINANTS OF SIZE AND SHAPE

The shape and size of a volcano are controlled by several factors. These include: (1) the volume of volcanic products, (2) the interval length between eruptions, (3) the composition of volcanic products, (4) the variety of volcanic eruption types, (5) the geometry of the vent, and (6) the environment into which the volcanic products are erupted.

The volume of material released in any one eruption can vary enormously from a few cubic metres of magma to as much as 3,000 cubic kilometres. A series of small eruptions usually builds up mounds close to the vent, whereas large-volume eruptions tend to disperse their products over a

Figure 15: The lava dome of Mount St. Helens, Washington state, U.S., May 16, 1984. Following the great eruption of May 18, 1980, a dome of lava grew intermittently in the crater of the volcano.

greater distance. Effusive eruptions form lava plateaus or gently sloping shield volcanoes; moderately explosive eruptions form stratovolcanoes; and giant explosive eruptions form plateaus of lava or ash flows and almost always form a caldera several kilometres in diameter over the eruption site. Naturally, since many other factors are involved in determining volcanic landforms, there are exceptions to these rules.

If a volcano has consistent eruption habits, its landform will reflect that character. The shape of the huge but gently sloping shield volcano Mauna Loa, for example, indicates a long record of eruption of fluid lava flows, while the beautiful, symmetrical shape of the stratovolcano Mount Fuji indicates a long record of moderately explosive eruptions from its summit that produce alternating layers of ash and lava. In contrast to simple shield and stratovolcanoes, many volcanoes change their eruptive habits—both in eruption type and in the location of their vents—over time. This results in a mixture of volcanic landforms called a complex volcano.

Composi-
tions and
properties
of volcanic
rock

The chemical composition of magma affects its physical properties, which in turn have a major influence on the landform built by a volcanic eruption. Four common volcanic rock types are listed in Table 2: basalt, andesite, dacite, and rhyolite. As the silica content increases, these rock types generally become more viscous; as the magmatic gas content increases, they become more explosive. Other physical properties are, however, important in determining the character of lava flows. For example, hot basaltic lava produces flows with smooth to ropy surfaces. These flows, known as pahoehoe, tend to flow farther than the cooler aa flows of the same chemical composition that have rough, broken surfaces. (See above *Lava flows.*)

The geometry of the vent or vents also exerts profound control on volcanic landforms. Multiple point-source vents that erupt only once or at most a few times form a volcanic field of dozens of small cinder cones rather than a single large volcanic edifice. Volcanic vents in the form of long fissures usually build up a thick lava plateau (especially when erupting voluminous amounts of fluid lava) or a low volcanic mound. Hekla Volcano in Iceland is transitional between plateau-building fissure eruptions and eruptions from a single major vent that produce a symmetrical stratovolcano. Hekla erupts from a fissure that is parallel to the Mid-Atlantic Ridge and about 20 kilometres in length. Viewed along the fissure, Hekla looks like a stratovolcano; perpendicular to the fissure, it appears as an elongate ridge.

Finally, but of great importance, is the environment where the volcanic products are erupted—into the atmosphere, under water, or under ice. Submarine volcanoes are surprisingly similar to their counterparts on land, but their slopes are generally steeper because water cools the lavas more rapidly. Deep submarine volcanism tends to be less explosive because the pressure of the water retards explosive boiling. Subglacial volcanism produces landforms that are dramatically different from those produced by subaerial volcanism. This is particularly apparent in Iceland, where glaciers covered the entire island 15,000 years ago, and large ice caps still cover extensive areas today. Fissure eruptions beneath the ice form steep ridges of broken lava fragments rather than lava-flow plateaus, while subglacial eruptions from point-source vents that erupt repeatedly form table mountains. Table mountain volcanoes have steep sides of pillow lavas—sacklike structures that form

when flows of basaltic lava are extruded into the ocean, a deep lake, or a water-filled cavern within ice. These pillow structures are capped by several tens of metres of broken lava fragments from explosive shallow-water eruptions. The broken lava fragments in turn are overlain by shield-building lava flows erupted above the glacial surface.

Hot springs and geysers

Hot springs and geysers also are manifestations of volcanic activity. They result from the interaction of groundwater with magma or with solidified but still-hot igneous rocks at shallow depths.

Yellowstone National Park in the United States is one of the most famous areas of hot springs and geysers in the world. The total heat flux from these thermal features is estimated to be 300 megawatts (300 million watts). The last great eruption at Yellowstone occurred about 630,000 years ago when some 1,000 cubic kilometres (240 cubic miles) of rhyolitic pumice and ash were ejected in huge pyroclastic flows and resulted in the formation of a caldera—a large circular or oval depression caused by collapse of the surface following magma removal—approximately 45 by 75 kilometres (28 by 47 miles) in size. Yellowstone Lake now occupies part of this giant caldera. Since that last great outburst, about 1,200 cubic kilometres of rhyolite lava flows and domes have erupted in numerous smaller events. The cooling roots of such past eruptions, or possibly the new intrusions of magma at shallow depth, are the heat sources for the Yellowstone hot springs and geysers.

Geysers are hot springs that intermittently spout a column of hot water and steam into the air. This action is caused by the water in deep conduits beneath a geyser approaching or reaching the boiling point. At 300 metres (about 1,000 feet) below the surface, the boiling point of water increases to approximately 230° C (450° F) because of the increased pressure of the overlying water. As bubbles of steam or dissolved gas begin to form, rise, and expand, hot water spills from the geyser's vent, lowering the pressure on the water column below. Water at depth then momentarily exceeds its boiling point and flashes into steam, forcing additional water from the vent. This chain reaction continues until the geyser exhausts its supply of boiling water.

After a geyser stops spouting, the conduits at depth refill with groundwater, and reheating begins again. In geysers such as Yellowstone's Old Faithful, the spouting and recharge period is quite regular. This famous geyser has gushed to heights of 30 to 55 metres about every 90 minutes for more than 100 years. If Old Faithful's eruption lasts only a minute or two, the next interval will be shorter than average, while a four-minute eruption will be followed by a longer interval. Other geysers have much more erratic recharge times.

Volcanism and tectonic activity

Taking a more distant view of volcanic landforms from space, one can see that most volcanoes group together to form linear to arcuate belts across the Earth's surface. It is now clear that these volcanic chains are closely related to global tectonic activity. Many active volcanoes are located in the so-called "Ring of Fire" made up of island arcs and mountain ranges bordering the Pacific Ocean (see the map, Figure 17). The concept of seafloor spreading and, more

Table 2: Common types of volcanic rock

name	silica (SiO₂) content (percent)	major minerals	colour	approximate density with no voids (g/cm³)
basalt	45–53	Ca feldspar, pyroxene, olivine	dark gray	3.0
andesite	53–62	CaNa feldspar, pyroxene, amphibole	medium gray	2.9
dacite	62–70	Na feldspar, amphibole, biotite, quartz	light gray* to tan	2.8
rhyolite	70–78	K, Na feldspars, quartz, biotite	light gray* to pink	2.7

George Marler/National Park Service

broadly, the theory of plate tectonics offer a logical explanation for the location of most volcanoes.

VOLCANOES RELATED TO PLATE BOUNDARIES

Topographic maps reveal the locations of large earthquakes and indicate the boundaries of the 12 major tectonic plates. For example, the Pacific Plate is bounded by the earthquake zones of New Zealand, New Guinea, the Mariana Islands, Japan, Kamchatka, the Aleutian Islands, western North America, the East Pacific Rise, and the Pacific-Antarctic Ridge.

The Earth's plates, which move horizontally with respect to one another at a rate of a few centimetres per year, form three basic types of boundaries: convergent, divergent, and side-slipping. Japan and the Aleutian Islands are located on convergent boundaries where the Pacific Plate is moving beneath the adjacent continental plates—a process known as subduction. The San Andreas Fault system in California exemplifies a side-slipping boundary where the Pacific Plate is moving northwest relative to the North American Plate—a process called strike-slip, or transform, faulting. The East Pacific Rise is representative of a divergent boundary where the Pacific Plate and the Nazca Plate (west of South America) are moving apart—a process known as rifting.

Volcanoes occur along both subduction and rift zones but are generally absent along strike-slip plate margins. Most subduction-related volcanoes are explosive and build stratovolcanoes, while rift volcanoes tend to be more effusive and build shield volcanoes, though there are exceptions to
Figure 17: Volcanoes and thermal fields that have been active during the past 10,000 years.

both these generalities. Subduction-related volcanoes erupt basalt, andesite, dacite, and rhyolite, andesite being the predominant rock type. Rift-related volcanoes, especially on the ocean floor, erupt mainly basalt.

Volcanoes of the Pacific Plate

The volcanoes on the western and northern margin of the Pacific Plate (New Zealand, New Guinea, Mariana Islands, Japan, Kamchatka, and the Aleutian Islands) are all subduction volcanoes. The rift volcanoes are largely hidden along the submarine crest of the East Pacific Rise and the Pacific-Antarctic Ridge at depths of 2 to 3 kilometres (1.2 to 1.9 miles) below sea level. The Cascade volcanoes in the northwestern United States and the volcanoes in Mexico and Central America are related to the subduction under the North American Plate of the small Juan de Fuca and Cocos plates, which are on the east side of the Pacific Plate. Similarly, the volcanoes of the Andes are related to the subduction of the Nazca Plate beneath the South American Plate.

A conceptual model of how subduction and rift volcanoes may form is shown schematically in Figure 18. Of the more than 1,450 volcanoes listed in Table 1, 80 percent occur along subduction zones, and 15 percent occur along rift zones. These percentages are somewhat misleading, however, because most of the Earth's rift zones are about 2 to 3 kilometres below sea level, where volcanic activity is hard to detect. At those depths active submarine volcanoes have yet to be observed, though many hydrothermal areas have been found along submarine rift zones by research submersibles. Iceland, a segment of the Mid-Atlantic Ridge that emerges above sea level, has 70 volcanoes that have erupted during the past 10,000 years. If this is a typical number for a rift system, there may be several thousand potentially active volcanoes along the oceanic ridges that are the surface expressions of the world rift system.

Subduction volcanoes.   As an oceanic plate is subducted beneath a continental plate, seafloor sediments rich in water and carbon dioxide are carried beneath the overriding plate. These compounds may act as fluxes, reducing the melting temperature of magma. Although the process is not clearly understood, magma apparently forms and rises by buoyancy from a depth of 100 to 200 kilometres. Subduction-zone volcanoes occur on the overriding plate and are offset inland from the actual plate boundary along the ocean trench.

The rising subduction-zone magma is probably basaltic in composition and is formed by the partial melting of mantle rocks. As the rising magma moves slowly up through the continental crust of the overriding plate, however, two things may occur to increase significantly the silica content of the magma. Crystallization of olivine and pyroxene minerals from the basalt can leave the residual melt enriched in silica and depleted in magnesium, iron, and calcium. This process is called fractional crystallization. Also, basaltic magmas have enough excess heat to partially melt the continental host rocks through which they are ascending. Because continental rocks are generally higher in silica, potassium, and sodium than are oceanic rocks, this process of assimilation and mixing can also play an important role in producing the wide range of compositions that occur in rocks from subduction volcanoes.

The additional gas content of many magmas at subduction volcanoes (which, coupled with their often high-viscosity magma, makes them dangerously explosive) may be explained by more than one process. Additional water and carbon dioxide may come from both subducted seafloor sediments and assimilated crustal rocks. Furthermore, any fractional crystallization tends to concentrate volatile elements in the residual melt. If volcanic gases form separate fluid phases within batches of ascending magma (as carbon dioxide gas is most likely to do), these fluid phases may ascend more rapidly than the overall magma body and be concentrated in the upper portion. Sudden expansion of these hot volcanic gases at atmospheric pressure is the apparent reason for the highly explosive nature of many subduction volcanoes.

Rift volcanoes.   Rift volcanoes form when magma rises into the gap between diverging plates. They thus occur at or near actual plate boundaries. Measurements in Iceland suggest that the separation of plates is a continuous process but that the fracturing is intermittent, analogous to a rubber band that is slowly stretched until it snaps. Earthquake swarms and volcanic eruptions occur when the stretching exceeds the strength of the near-surface rocks, which then fracture along steeply dipping cracks parallel to the rift. Basaltic magma rising along these fractures causes Icelandic-type fissure eruptions.

Rift volcanoes in continental locations such as the East African Rift System are more complex. Assimilation of continental crust apparently gives them some of the characteristics more generally associated with subduction volcanoes, such as having a wider range of rock types and explosive habits.

Encyclopædia Britannica, Inc.
Figure 18: Volcanic activity tends to be found at subduction zones (convergent plate margins), where an oceanic plate slides beneath a continental plate; at rift zones (divergent margins), where two plates pull slowly apart; or at "hot spots," where plumes of lava rise from deep within the Earth's mantle. Volcanoes are not generally found at strike-slip zones (transform faults), where two plates slide laterally past each other.

INTRAPLATE VOLCANISM

"Hot-spot" volcanoes

The 5 percent of known volcanoes in the world that are not closely related to plate margins are generally regarded as intraplate, or "hot-spot," volcanoes. A hot spot is believed to be related to the rising of a deep-mantle plume, which is caused by very slow convection of highly viscous material in the Earth's mantle. As hot but solid mantle rock moves upward, partial melting may occur from the lowering of its pressure-dependent melting temperature. Where a lithospheric plate moves over a hot spot, a chain of volcanic islands may be created. As the plate moves, the older volcanoes are transported away from the magma source and become extinct. The younger, active volcanoes are clustered at the end of the chain over the hot spot. It is not known how a volcanic hot spot maintains its position for millions of years while a plate passes over it. Detailed seismic sounding of the mantle should increase the understanding of the mechanism controlling hot spots.

Hawaiian volcanoes are the best examples of hot-spot volcanoes. The five volcanoes that form the island of Hawaii at the southeast end of the Hawaiian chain are all less than one million years old. Two of these, Kilauea and Mauna Loa, are two of the most active volcanoes in the world. Northwestward along the Hawaiian chain each island is progressively older. The extinct volcano or volcanoes that formed the island of Kauai are about five million years old. Topographic maps show a major submarine continuation of the Hawaiian Ridge to the northwest of the Hawaiian Islands and then a dogleg bend into the Emperor Seamounts, which comprise an entirely submarine ridge continuing northward to the edge of the Pacific Plate.

Ages of rocks obtained by dredging and drilling the Emperor Seamounts indicate that they are a continuation of the Hawaiian chain and that the Hawaiian hot spot has been active for at least 80 million years. The Pacific Plate has moved over this centre of volcanism, first northward and later northwestward, at a rate of approximately 8 to 10 centimetres (3 to 4 inches) per year. The bend between the Emperor Seamounts and the Hawaiian Ridge occurred about 45 million years ago and indicates a significant shift in the direction of movement of the Pacific Plate.

Small, isolated intraplate volcanoes may not be produced by a hot spot but rather may be the result of deep fractures within the plates that allow pockets of magma to leak to the surface. These pockets originate in the low-velocity layer, so named because earthquake waves travel more slowly through the hot, plastically deforming rocks of this region than in the overlying rigid plates. The low-velocity layer begins about 50 to 150 kilometres below the surface and extends to a depth of roughly 300 kilometres. A small amount (a few percent) of the low-velocity layer may be molten. Once a sufficient volume of magma forms in the subsurface, it tends to rise from its own buoyancy. Any fracture system at the plate margins or within the plates will facilitate this process.

Volcanoes and geothermal energy

Geothermal energy is plentiful, but geothermal power is not. Temperatures increase below the Earth's surface at a rate of about 30° C per kilometre in the first 10 kilometres (roughly 90° F per mile in the first 6 miles) below the surface. This internal heat of the Earth is an immense store of energy. In the upper 10 kilometres of rock beneath the conterminous United States, it amounts to 3.3×10^{25} joules, or about 6,000 times the energy contained in the world's oil reserves. The problem in utilizing geothermal energy is extracting it.

Concentrating the Earth's heat energy

The natural escape of the Earth's heat through its surface averages only 0.06 watt per square metre (0.006 watt per square foot). To make geothermal power practical, some special situation must exist to concentrate the Earth's heat energy in a small area. Underground reservoirs of steam or hot water that can be funneled into a drill hole provide this special situation. Some geothermal steam wells can produce 25 megawatts of thermal power, an amount equal to the normal heat flux of more than 400 square kilometres (150 square miles) of land surface. The key to this concentration is the transfer of heat from deeper levels to the near surface by the ascending magma associated with volcanism. Magma at temperatures close to 1,200° C (2,200° F) moves upward to depths of only a few kilometres, where it transfers heat by conduction to groundwater. The groundwater then circulates by convection and forms large underground reservoirs of hot water and steam. Some of this thermal water may escape to the surface as hot springs or geysers.

Holes drilled into a subsurface geothermal system allow rapid transfer of hot water or steam to the surface. At The Geysers, a geothermal field north of San Francisco, superheated steam is directly tapped from porous underground reservoirs. In most other geothermal fields, the hot water is at or below its subsurface boiling temperature—about 300° C (570° F) at a depth of 1 kilometre. The hot water and steam produced from geothermal wells are used as the energy source to drive turbine generators in electric power plants. Hot water from lower-temperature geothermal reservoirs can be used for space heating and other applications. This form of geothermal power is utilized extensively in Iceland.

Some geothermal systems act as natural distilleries in the subsurface, dissolving trace amounts of gold, silver, and other rare elements from their host rocks. These elements may then be deposited at places where changes in temperature, pressure, or composition favour precipitation. Many hydrothermal ore deposits have been formed by once active—and in a few cases still active—geothermal systems. Gold is one more legacy of volcanism.

BIBLIOGRAPHY.

General works. On an introductory level, ROBERT DECKER and BARBARA DECKER, *Volcanoes*, 4th ed. (2005), emphasizes physical processes and the relationship of volcanoes to plate tectonics. Volcanoes, eruptions, hazards, and the benefits of and myths surrounding volcanoes are described in RICHARD V. FISHER, GRANT HEIKEN, and JEFFREY B. HULEN, *Volcanoes: Crucibles of Change* (1997). A well-illustrated account of major volcanic eruptions with a chapter on monitoring active volcanoes is given in TIME-LIFE BOOKS, *Volcano* (1982). A history of the myths and science of volcanoes is presented in MAURICE KRAFFT and KATIA KRAFFT, *Volcanoes: Fire from the Earth*, trans. by PAUL G. BAHN (1993; originally published in French, 1992). HARALDUR SIGURDSSON, *Melting the Earth: The History of Ideas on Volcanic Eruptions* (1999), discusses the evolution of thought from 5th-century-BC Greece to the present.

Volcanic hazards and how humans cope with them are presented in STEPHEN L. HARRIS, *Agents of Chaos: Earthquakes, Volcanoes, and Other Natural Hazards* (1990); and KERRY SIEH and SIMON LEVAY, *The Earth in Turmoil: Earthquakes, Volcanoes, and Their Impact on Humankind* (1998). R. SCARPA and R.I. TILLING (eds.), *Monitoring and Mitigation of Volcano Hazards* (1996), discusses tools for reducing the risks of volcanic activity. KENNETH WOHLETZ and GRANT HEIKEN, *Volcanology and Geothermal Energy* (1992), presents the relationship between volcanism and geothermal exploration.

Individual volcanoes and volcano directories. Articles on the 1991 eruption of Mount Pinatubo are collected in CHRISTOPHER G. NEWHALL and RAYMONDO S. PUNONGBAYAN (eds.), *Fire and Mud: Eruptions and Lahars of Mount Pinatubo, Philippines* (1996). The world's largest volcano is described in J.M. RHODES and JOHN P. LOCKWOOD (eds.), *Mauna Loa Revealed: Structure, Composition, History, and Hazards* (1995). Hawaiian volcanoes and the geology of Hawaii are discussed in GORDON A. MACDONALD, AGATIN T. ABBOTT, and FRANK L. PETERSON, *Volcanoes in the Sea*, 2nd ed. (1983).

A description of 15 famous volcanoes from Stromboli to Pinatubo and how humans have coped with them is given in ALWYN SCARTH, *Vulcan's Fury: Man Against the Volcano* (1999, reissued 2001). A monumental work by prominent volcanologists is presented in HARALDUR SIGURDSSON (ed.), *Encyclopedia of Volcanoes* (2000). An excellent catalog of world volcanoes and their past eruptions is given in TOM SIMKIN and LEE SIEBERT, *Volcanoes of the World: A Regional Directory, Gazetteer, and Chronology of Volcanism During the Last 10,000 Years*, 2nd rev. ed. (1994).

Volcanologists and their work. Popular books about volcanoes and the scientists who study them include JOSEPH CONE, *Fire Under the Sea: The Discovery of the Most Extraordinary Environment on Earth—Volcanic Hot Springs on the Ocean Floor* (1991); RICHARD V. FISHER, *Out of the Crater: Chronicles of a Volcanologist* (1999), on the personal adventures of a well-known scientist; and DICK THOMPSON, *Volcano Cowboys: The Rocky Evolution of a Dangerous Science* (2000, reissued 2002), on the trials and tribulations of scientists studying two catastrophic eruptions, Mount St. Helens and Pinatubo.   (R.W.De./B.B.De.)

Voltaire

Voltaire, one of the greatest French authors, though only a few of his works are still read, is held in worldwide repute as a courageous crusader against tyranny, bigotry, and cruelty. He embodies characteristic qualities of the French mind—a critical capacity, wit, and satire. His whole work vigorously propagates an ideal of progress to which men of all nations have remained responsive. His long life spans the last years of classicism and the eve of the revolutionary era; during this age of transition his works and activities influenced the direction taken by European civilization.

Cliche Musees Nationaux Paris

Voltaire, portrait by an unknown artist after a portrait by Nicolas de Largillière, 1718. In the Château de Versailles.

Heritage and youth. Voltaire's background was middle class. According to his birth certificate he was born François-Marie Arouet in Paris on November 21, 1694, but the hypothesis that his birth was kept secret cannot be dismissed, for he stated on several occasions that in fact it took place on February 20, 1694. He believed that he was the son of an officer named Rochebrune, who was also a songwriter. He had no love for either his putative father, François Arouet, a onetime notary who later became receiver in the Cour des Comptes (audit office), or his elder brother Armand. Almost nothing is known about his mother of whom he hardly said anything. Having lost her when he was seven, he seems to have become an early rebel against family authority. He attached himself to his godfather, the Abbé de Châteauneuf, a freethinker and epicurean who presented the boy to the famous courtesan Ninon de Lenclos when she was in her 84th year. But it is doubtless that he owed his positive outlook and his sense of reality to his bourgeois origins.

He attended the Jesuit college of Louis-le-Grand in Paris, where he learned to love literature, the theatre, and social life. While he appreciated the classical taste the college instilled in him, the religious instruction of the fathers served only to arouse his skepticism and mockery. He witnessed the last sad years of Louis XIV and was never to forget the distress and the military disasters of 1709 nor the horrors of religious persecution. He retained, however, a degree of admiration for the sovereign, and he remained convinced that the enlightened kings are the indispensable agents of progress.

He decided against the study of law after he left college. Employed as secretary at the French embassy in The Hague, he became infatuated with the daughter of an adventurer. Fearing scandal, the French ambassador sent him back to Paris. Despite his father's wishes, he wanted to devote himself wholly to literature, and he frequented the Temple, then the centre of free-thinking society. After the death of Louis XIV, under the morally relaxed Regency, Voltaire became the wit of Parisian society, and his epigrams were widely quoted. But when he dared to mock the dissolute regent, the Duc d'Orléans, he was banished from Paris and then imprisoned in the Bastille for nearly a year (1717). Behind his gay facade, he was fundamentally serious and set himself to learn the accepted literary forms. In 1718, after the success of *Oedipe,* the first of his tragedies, he was acclaimed as the successor of the great classical dramatist Jean Racine and thenceforward adopted the name of Voltaire. The origin of this pen name remains doubtful. It is not certain that it is the anagram of Arouet le jeune (*i.e.,* the younger). Above all he desired to be the Virgil that France had never known. He worked at an epic poem whose hero was Henry IV, the king beloved by the French people for having put an end to the wars of religion. This *Henriade* is spoiled by its pedantic imitation of Virgil's *Aeneid,* but his contemporaries saw only the generous ideal of tolerance that inspired the poem. These literary triumphs earned him a pension from the regent and the warm approval of the young queen, Marie. He thus began his career as court poet.

Early drama and poetry

United with other thinkers of his day—literary men and scientists—in the belief in the efficacy of reason, Voltaire was a Philosophe, as the 18th century termed it. In the salons he professed an aggressive Deism, which scandalized the devout. He became interested in England, the country that tolerated freedom of thought; he visited the Tory leader Viscount Bolingbroke, exiled in France—a politician, an orator, and a philosopher whom Voltaire admired to the point of comparing him to Cicero. On Bolingbroke's advice he learned English in order to read the philosophical works of John Locke. His intellectual development was furthered by an accident: as the result of a quarrel with a member of one of the leading French families, the Chevalier de Rohan, who had made fun of his adopted name, he was beaten up, taken to the Bastille, and then conducted to Calais on May 5, 1726, from where he set out for London. His destiny was now exile and opposition.

Exile to England. During a stay that lasted more than two years he succeeded in learning the English language; he wrote his notebooks in English and to the end of his life he was able to speak and write it fluently. He met such English men of letters as Alexander Pope, Jonathan Swift, and William Congreve, the philosopher George Berkeley, and Samuel Clarke, the theologian. He was presented at court, and he dedicated his *Henriade* to Queen Caroline. Though at first he was patronized by Bolingbroke, who had returned from exile, it appears that he quarrelled with the Tory leader and turned to Sir Robert Walpole and the liberal Whigs. He admired the liberalism of English institutions, though he was shocked by the partisan violence. He envied English intrepidity in the discussion of religious and philosophic questions and was particularly interested in the Quakers. He was convinced that it was because of their personal liberty that the English, notably Sir Isaac Newton and John Locke, were in the forefront of scientific thought. He believed that this nation of merchants and sailors owed its victories over Louis XIV to its economic advantages. He concluded that even in literature France had something to learn from England; his experience of Shakespearean theatre was overwhelming, and, however much he was shocked by the "barbarism" of the productions, he was struck by the energy of the characters and the dramatic force of the plots.

Meetings with English men of letters

Return to France. He returned to France at the end of 1728 or the beginning of 1729 and decided to present En-

gland as a model to his compatriots. His social position was consolidated. By judicious speculation he began to build up the vast fortune that guaranteed his independence. He attempted to revive tragedy by discreetly imitating Shakespeare. *Brutus,* begun in London and accompanied by a *Discours à milord Bolingbroke,* was scarcely a success in 1730; *La Mort de César* was played only in a college (1735); in *Eriphyle* (1732) the apparition of a ghost, as in *Hamlet,* was booed by the audience. *Zaïre,* however, was a resounding success. The play, in which the sultan Orosmane, deceived by an ambiguous letter, stabs his prisoner, the devoted Christian-born Zaïre, in a fit of jealousy, captivated the public with its exotic subject.

Interest in history

At the same time, Voltaire had turned to a new literary genre: history. In London he had made the acquaintance of Fabrice, a former companion of the Swedish king Charles XII. The interest he felt for the extraordinary character of this great soldier impelled him to write his life, *Histoire de Charles XII* (1731), a carefully documented historical narrative that reads like a novel. Philosophic ideas began to impose themselves as he wrote: the King of Sweden's exploits brought desolation, whereas his rival Peter the Great brought Russia into being, bequeathing a vast, civilized empire. Great men are not warmongers; they further civilization—a conclusion that tallied with the example of England. It was this line of thought that Voltaire brought to fruition, after prolonged meditation, in a work of incisive brevity: the *Lettres philosophiques* (1734). These fictitious letters are primarily a demonstration of the benign effects of religious toleration. They contrast the wise Empiricist psychology of Locke with the conjectural lucubrations of René Descartes. A philosopher worthy of the name, such as Newton, disdains empty, a priori speculations; he observes the facts and reasons from them. After elucidating the English political system, its commerce, its literature, and the Shakespeare almost unknown to France, Voltaire concludes with an attack on the French mathematician and religious philosopher Pascal: the purpose of life is not to reach heaven through penitence but to assure happiness to all men by progress in the sciences and the arts, a fulfillment for which their nature is destined. This small, brilliant book is a landmark in the history of thought: not only does it embody the philosophy of the 18th century, but it also defines the essential direction of the modern mind.

Life with Mme du Châtelet. Scandal followed publication of this work that spoke out so frankly against the religious and political establishment. When a warrant of arrest was issued in May of 1734, Voltaire took refuge in the château of Mme du Châtelet at Cirey in Champagne and thus began his liaison with this young, remarkably intelligent woman. He lived with her in the château he had renovated at his own expense. This period of retreat was interrupted only by a journey to the Low Countries in December 1736—an exile of a few weeks became advisable after the circulation of a short, daringly epicurean poem called "Le Mondain."

The life these two lived together was both luxurious and studious. After *Adélaïde du Guesclin* (1734), a play about a national tragedy, he brought *Alzire* to the stage in 1736 with great success. The action of *Alzire*—in Lima, Peru, at the time of the Spanish conquest—brings out the moral superiority of a humanitarian civilization over methods of brute force. Despite the conventional portrayal of "noble savages," the tragedy kept its place in the repertory of the Comédie-Française for almost a century. Mme du

Interest in science and metaphysics

Châtelet was passionately drawn to the sciences and metaphysics and influenced Voltaire's work in that direction. A "gallery" or laboratory of the physical sciences was installed at the château, and they composed a memorandum on the nature of fire for a meeting of the Académie des Sciences. While Mme du Châtelet was learning English in order to translate Newton and *The Fable of the Bees* of Bernard de Mandeville, Voltaire popularized, in his *Éléments de la philosophie de Newton* (1738), those discoveries of English science that were familiar only to a few advanced minds in France, such as the astronomer and mathematician Pierre-Louis de Maupertuis. At the same time, he continued to pursue his historical studies. He began *Le Siècle*

de Louis XIV, sketched out a universal history of kings, wars, civilization and manners that became the *Essai sur les moeurs,* and plunged into biblical exegesis. Mme du Châtelet herself wrote an *Examen,* highly critical of the two Testaments. It was at Cirey that Voltaire, rounding out his scientific knowledge, acquired the encyclopaedic culture that was one of the outstanding facets of his genius.

Because of a lawsuit, he followed Mme du Châtelet to Brussels in May 1739, and thereafter they were constantly on the move between Belgium, Cirey, and Paris. Voltaire corresponded with the crown prince of Prussia, who, rebelling against his father's rigid system of military training and education, had taken refuge in French culture. When the prince acceded to the throne as Frederick II (the Great), Voltaire visited his disciple first at Cleves (Kleve), Germany), then at Berlin. When the War of the Austrian Succession broke out, Voltaire was sent to Berlin (1742–43) on a secret mission to rally the King of Prussia—who was proving himself a faithless ally—to the assistance of the French Army. Such services—as well as his introduction of his friends the brothers d'Argenson, who became ministers of war and foreign affairs, respectively, to the protection of Mme de Pompadour, the mistress of Louis XV—brought him into favour again at Versailles. After his poem celebrating the victory of Fontenoy (1745), he was appointed historiographer, gentleman of the king's chamber, and academician. His tragedy *Mérope,* about the mythical Greek queen, won public acclaim on the first night (1743). The performance of *Mahomet,* in which Voltaire presented the founder of Islām as an imposter, was forbidden, however, after its successful production in 1742. He amassed a vast fortune through the manipulations of Joseph Pâris Duverney, the financier in charge of military supplies, who was favoured by Mme de Pompadour. In this ambience of well-being, he began a liaison with his niece Mme Denis, a charming widow, without breaking off his relationship with Mme du Châtelet.

Yet he was not spared disappointments. Louis XV disliked him, and the pious Catholic faction at court remained acutely hostile. He was guilty of indiscretions. When Mme du Châtelet lost large sums at the Queen's gaming table, he said to her in English: "You are playing with cardsharpers"; the phrase was understood, and he was forced to go into hiding at the country mansion as the guest of the Duchesse du Maine in 1747. Ill and exhausted by his restless existence, he at last discovered the literary form that ideally fitted his lively and disillusioned temper: he wrote his first *contes* (stories). *Micromégas* (1752) measures the littleness of man in the cosmic scale; *Vision de Babouc* (1748) and *Memnon* (1749) dispute the philosophic optimism of Gottfried Wilhelm Leibniz and Alexander Pope. *Zadig* (1747) is a kind of allegorical autobiography: like Voltaire, the Babylonian sage Zadig suffers persecution, is pursued by ill fortune, and ends by doubting the tender care of Providence for human beings.

The great crisis of his life was drawing near. In 1748 at Commercy, where he had joined the court of Stanisław (the former king of Poland), he detected the love affair of Mme du Châtelet and the poet Saint-Lambert, a slightly ludicrous passion that ended tragically. On September 10, 1749, he witnessed the death in childbirth of this uncommonly intelligent woman who for 15 years had been his guide and counsellor. He returned in despair to the house in Paris where they had lived together; he rose in the night and wandered in the darkness, calling her name.

Death of Mme du Châtelet

Later travels. The failure of some of his plays aggravated his sense of defeat. He had attempted the *comédie larmoyante,* or "sentimental comedy," that was then fashionable: after *L'Enfant prodigue* (1736), a variation of the prodigal son theme, he adapted William Wycherley's satiric Restoration drama *The Plain-Dealer* to his purpose, entitling it *La Prude;* he based *Nanine* (1749) on a situation taken from Samuel Richardson's novel *Pamela,* but all without success. The court spectacles he directed gave him a taste for scenic effects, and he contrived a sumptuous decor, as well as the apparition of a ghost, for *Sémiramis* (1748), but his public was not captivated. His enemies compared him with Prosper Jolyot, sieur de Crébillon, who was pre-eminent among French writers of

tragedy at this time. Though Voltaire used the same subjects as his rival (*Oreste, Sémiramis*), the Parisian audience preferred the plays of Crébillon. Exasperated and disappointed, he yielded to the pressing invitation of Frederick II and set out for Berlin on June 28, 1750.

At the moment of his departure a new literary generation, reacting against the ideas and tastes to which he remained faithful, was coming to the fore in France. Disseminators of the philosophical ideas of the time, such as Denis Diderot, Baron d'Holbach, and their friends, were protagonists of a thoroughgoing Materialism and regarded Voltaire's Deism as too timid. Others had rediscovered with Jean-Jacques Rousseau the poetry of Christianity. All in fact preferred the charm of sentiment and passion to the enlightenment of reason. As the years passed, Voltaire became increasingly more isolated in his glory.

At first he was enchanted by his sojourn in Berlin and Potsdam, but soon difficulties arose. After a lawsuit with a moneylender, and quarrels with prominent noblemen, he started a controversy with Maupertuis (the president of Frederick's academy of science, the Berlin Academy) on scientific matters. In a pamphlet entitled "Diatribe du docteur Akakia" (1752), he covered him with ridicule. The King, enraged, consigned "Akakia" to the flames and gave its author a thorough dressing down. Voltaire left Prussia on March 26, 1753, leaving Frederick exasperated and determined to punish him. On the journey he was held under house arrest at an inn at Frankfurt, by order of the Prussian resident. Louis XV forbade him to approach Paris. Not knowing where to turn, he stayed at Colmar for more than a year. At length he found asylum at Geneva, where he purchased a house called Les Délices, at the same time securing winter quarters at Lausanne.

Major historical studies

He now completed his two major historical studies. *Le Siècle de Louis XIV* (1751), a book on the century of Louis XIV, had been prepared after an exhaustive 20-year interrogation of the survivors of *le grand siècle*. Voltaire was particularly concerned to establish the truth by collecting evidence from as many witnesses as possible, evidence that he submitted to exacting criticism. His desire was to write the nation's history by means of an examination of its arts and sciences and of its social life, but military events and politics still occupy a large place in his survey. The *Essai sur les moeurs*, the study on customs and morals that he had begun in 1740 (first complete edition, 1756), traced the course of world history since the end of the Roman Empire and gave an important place to the Eastern and Far Eastern countries. Voltaire's object was to show humanity slowly developing beyond barbarism. He supplemented these two works with one on Russian history during the reign of Peter the Great, *Histoire de l'empire de Russie sous Pierre le Grand* (1759–63), the *Philosophie de l'histoire* (1765), and the *Précis du siècle de Louis XV* (1768).

At Geneva, he had at first been welcomed and honoured as the champion of tolerance. But soon he made those around him feel uneasy. At Les Délices his presentation of plays was stopped, in accordance with the law of the republic of Geneva, which forbade both public and private theatre performances. Then there was his mock-heroic poem "La Pucelle" (1755), a most improper presentation of Joan of Arc (*La Pucelle d'Orléans*), which the booksellers printed in spite of his protests.

Attracted by his volatile intelligence, Calvinist pastors as well as women and young people thronged to his salon. Yet he soon provoked the hostility of important Swiss intellectuals. The storm broke in November 1757, when volume seven of Diderot's *Encyclopédie* was published. Voltaire had inspired the article on Geneva that his fellow philosopher Jean d'Alembert had written after a visit to Les Délices; not only was the city of Calvin asked to build a theatre within its walls but also certain of its pastors were praised for their doubts of Christ's divinity. The scandal sparked a quick response: the *Encyclopédie* was forced to interrupt publication, and Rousseau attacked the rational philosophy of the Philosophes in general in a polemical treatise on the question of the morality of theatrical performances, *Lettre à d'Alembert sur les spectacles* (1758). Rousseau's view that drama might well be

abolished marked a final break between the two writers.

Voltaire no longer felt safe in Geneva, and he longed to retire from these quarrels. In 1758 he wrote what was to be his most famous work, *Candide*. In this philosophical fantasy, the youth Candide, disciple of Doctor Pangloss (himself a disciple of the philosophical optimism of Leibniz), saw and suffered such misfortune that he was unable to believe that this was "the best of all possible worlds." Having retired with his companions to the shores of the Propontis, he discovered that the secret of happiness was "to cultivate one's garden," a practical philosophy excluding excessive idealism and nebulous metaphysics. Voltaire's own garden became Ferney, a property he bought at the end of 1758, together with Tourney in France, on the Swiss border. By crossing the frontier he could thus safeguard himself against police incursion from either country.

Candide

Achievements at Ferney. At Ferney, Voltaire entered on one of the most active periods of his life. Both patriarch and lord of the manor, he developed a modern estate, sharing in the movement of agricultural reform in which the aristocracy was interested at the time. He could not be true to himself, however, without stirring up village feuds and went before the magistrates on a question of tithes, as well as about the beating of one of his workmen. He renovated the church and had *Deo erexit Voltaire* ("Voltaire erected this to God") carved on the facade. At Easter Communion, 1762, he delivered a sermon on stealing and drunkenness and repeated this sacrilegious offense in the following year, flouting the prohibition by the bishop of Annecy, in whose jurisdiction Ferney lay. He meddled in Genevan politics, taking the side of the workers (or *natifs*, those without civil rights), and installed a stocking factory and watchworks on his estate in order to help them. He called for the liberation of serfs in the Jura, but without success, though he did succeed in suppressing the customs barrier on the road between Gex in the Jura and Geneva, the natural outlet for the produce of Gex. Such generous interventions in local politics earned him enormous popularity. In 1777 he received a popular acclamation from the people of Ferney. In 1815 the Congress of Vienna halted the annexation of Ferney to Switzerland in his honour.

His fame was now worldwide. "Innkeeper of Europe"—as he was called—he welcomed such literary figures as James Boswell, Giovanni Casanova, Edward Gibbon, the Prince de Ligne, and the fashionable philosophers of Paris. He kept up an enormous correspondence—with the Philosophes, with his actresses and actors, and with those high in court circles, such as the Duc de Richelieu (grandnephew of the Cardinal de Richelieu), the Duc de Choiseul, and Mme du Barry, Louis XV's favourite. He renewed his correspondence with Frederick II and exchanged letters with Catherine II of Russia.

Scientific, political, and religious controversies

There was scarcely a subject of importance on which he did not speak. In his political ideas, he was basically a liberal, though he also admired the authority of those kings who imposed progressive measures on their people. On the question of fossils, he entered into foolhardy controversy with the famous French naturalist Comte de Buffon. On the other hand, he declared himself a partisan of the Italian scientist Abbé Lazzaro Spallanzani against the hypothesis of spontaneous generation, according to which microscopic organisms are generated spontaneously in organic substances. He busied himself with political economy and revived his interest in metaphysics by absorbing the ideas of 17th-century philosophers Benedict de Spinoza and Nicolas Malebranche.

His main interest at this time, however, was his opposition to *l'infâme*, a word he used to designate the church, especially when it was identified with intolerance. For mankind's future he envisaged a simple theism, reinforcing the civil power of the state. He believed this end was being achieved when, about 1770, the courts of Paris, Vienna, and Madrid came into conflict with the pope; but this was to misjudge the solidarity of ecclesiastical institutions and the people's loyalty to the traditional faith. Voltaire's beliefs prompted a prodigious number of polemical writings. He multiplied his personal attacks, often stooping to low cunning; in his sentimental comedy *L'Écossaise* (1760),

he mimicked the eminent critic Élie Fréron, who had attacked him in reviews, by portraying his adversary as a rascally journalist who intervenes in a quarrel between two Scottish families. He directed *Le Sentiment des Citoyens* (1764) against Rousseau. In this anonymous pamphlet, which supposedly expressed the opinion of the Genevese, Voltaire, who was well informed, revealed to the public that Rousseau had abandoned his children. As author he used all kinds of pseudonyms: Rabbi Akib, Pastor Bourn, Lord Bolingbroke, M. Mamaki "interpreter of Oriental languages to the king of England," Clocpitre, Cubstorf, Jean Plokof—a nonstop performance of puppets. As a part-time scholar he constructed a personal *Encyclopédie,* the *Dictionnaire philosophique* (1764), enlarged after 1770 by *Questions sur l'Encyclopédie.* Among the mass of writings of this period are *Le Blanc et le noir* ("The White and the Black"), a philosophical tale in which Oriental fantasy contrasts with the realism of *Jeannot et Colin; Princesse de Babylone,* a panorama of European philosophies in the fairyland of *The Thousand and One Nights;* and *Le Taureau blanc,* a biblical tale.

Again and again Voltaire returned to his chosen themes: the establishment of religious tolerance, the growth of material prosperity, respect for the rights of man by the abolition of torture and useless punishments. These principles were brought into play when he intervened in some of the notorious public scandals of these years. For instance, when the Protestant Jean Calas, a merchant of Toulouse accused of having murdered his son in order to prevent his conversion to the Roman Catholic Church, was broken on the wheel while protesting his innocence (March 10, 1762), Voltaire, livid with anger, took up the case and by his vigorous intervention obtained the vindication of the unfortunate Calas and the indemnification of the family. But he was less successful in a dramatic affair concerning the 19-year-old Chevalier de La Barre, who was beheaded for having insulted a religious procession and damaging a crucifix (July 1, 1766). Public opinion was distressed by such barbarity, but it was Voltaire who protested actively, suggesting that the Philosophes should leave French territory and settle in the town of Cleves offered them by Frederick II. Although he failed to obtain even a review of this scandalous trial, he was able to reverse other judicial errors.

Late dramatic works

By such means he retained leadership of the philosophic movement. On the other hand, as a writer, he wanted to halt a development he deplored—that which led to Romanticism. He tried to save theatrical tragedy by making concessions to a public that adored scenes of violence and exoticism. For instance, in *L'Orphelin de la Chine* (1755), Lekain (Henri-Louis Cain), who played the part of Genghis Khan, was clad in a sensational Mongol costume. Lekain, whom Voltaire considered the greatest tragedian of his time, also played the title role of *Tancrède,* which was produced with a sumptuous decor (1760) and which proved to be Voltaire's last triumph. Subsequent tragedies, arid and ill-constructed and overweighted with philosophic propaganda, were either booed off the stage or not produced at all. He became alarmed at the increasing influence of Shakespeare; when he gave a home to a grandniece of the great 17th-century classical dramatist Pierre Corneille and on her behalf published an annotated edition of the famous tragic author, he inserted, after *Cinna,* a translation of *Julius Caesar,* convinced that such a confrontation would demonstrate the superiority of the French dramatist. He was infuriated by the Shakespearean translations of Pierre Le Tourneur in 1776, which stimulated French appreciation of this more robust, nonclassical dramatist, and dispatched an abusive *Lettre à l'Académie.* He never ceased to acknowledge a degree of genius in Shakespeare, yet spoke of him as "a drunken savage." He returned to a strict classicism in his last plays, but in vain, for the audacities of his own previous tragedies, timid as they were, had paved the way for Romantic drama.

It was the theatre that brought him back to Paris in 1778. Wishing to direct the rehearsals of *Irène,* he made his triumphal return to the city he had not seen for 28 years on February 10. More than 300 persons called on him the day after his arrival. On March 30 he went to the

Académie amid acclamations, and, when *Irène* was played before a delirious audience, he was crowned in his box. His health was profoundly impaired by all this excitement. On May 18 he was stricken with uremia. He suffered much pain on his deathbed, about which absurd legends were quickly fabricated; on May 30 he died, peacefully it seems. His nephew, the Abbé Mignot, had his body, clothed just as it was, swiftly transported to the Abbey of Scellières, where he was given Christian burial by the local clergy; the prohibition of such burial arrived after the ceremony. His remains were transferred to the Panthéon during the Revolution in July 1791.

Assessment. Voltaire's name has always evoked vivid reactions. Toward the end of his life he was attacked by the followers of Rousseau, and after 1800 he was held responsible for the Revolution. But the excesses of clerical reactionaries under the Restoration and the Second Empire rallied the middle and working classes to his memory. At the end of the 19th century, though conservative critics remained hostile, scientific research into his life and works was given impetus by Gustave Lanson. Voltaire himself did not hope that all his vast quantity of writings would be remembered by posterity. His epic poems and lyrical verse are virtually dead, as are his plays. But his *contes* are continually republished, and his letters are regarded as one of the great monuments of French literature. He bequeathed a lesson to humanity, which has lost nothing of its value. He taught men to think clearly; his was a mind at once precise and generous. "He is the necessary philosopher," wrote Lanson, "in a world of bureaucrats, engineers, and producers."   (R.H.Po.)

MAJOR WORKS

STORIES: *Les Voyages du baron de Gangan* (1739; an earlier version of *Micromégas,* 1752); *Zadig* (1747; Eng. trans. by J. Butt, 1964); *Vision de Babouc* (1748); *Candide* (1759; Eng. trans. by J. Spencer, 1966, and by Robert M. Adams, 1966); *Le Blanc et le noir* (1764; *The Two Genies,* 1895); *Jeannot et Colin* (1764); *La Princesse de Babylone* (1768; Eng. trans. 1969); *Le Taureau blanc* (1774; Eng. trans. 1774—attributed to Jeremy Bentham).

HISTORY: *Histoire de Charles XII* (1731; Eng. trans. by C. Messiter, 1860); *Le Siècle de Louis XIV* (1751; Eng. trans. by J.H. Brumfitt, 1966); *Histoire de l'empire de Russie sous Pierre le Grand* (1759–63; Eng. trans. 1763); *Précis du siècle de Louis XV* (1768; Eng. trans. 1774, 2 vol.).

PHILOSOPHY: *Lettres philosophiques* (1734); *Éléments de la philosophie de Newton* (1738; Eng. trans. 1738); *Essai sur les moeurs* (1756; Eng. trans. by Nugent, 1759); *Dictionnaire philosophique* (1764; Eng. trans. by H.I. Woolf, 1945); *Philosophie de l'histoire* (1765; Eng. trans. 1965).

PLAYS: *Zaïre* (1732; Eng. trans. by A. Wallace, 1854); *Alzire* (1736; *Tragedy of Alzira,* trans. by A. Hill, 1817); *Mérope* (1743; Eng. trans. by A. Hill, 1803).

OTHER WORKS: *La Henriade* (1728; Eng. trans. by R.G. Macgregor, 1854), an epic poem.

EDITIONS: *Les Oeuvres complètes* is an edition begun in 1968, directed first by THEODORE BESTERMAN, then by GILES BARBER, with introductions and notes in English and French. Among the works published are 51 volumes of Voltaire's complete correspondence and related documents. Theodore Besterman also translated and edited selections of Voltaire's correspondence, such as *The Love Letters of Voltaire to His Niece* (1958). See also THEODORE BESTERMAN and ANDREW BROWN (eds.), *Concordance to the Correspondence of Voltaire* (1977).

BIBLIOGRAPHY. A summary of scholarship on Voltaire is presented in MARY MARGARET H. BARR, *Century of Voltaire Study: A Bibliography of Writings on Voltaire, 1825–1925* (1929, reissued 1972), continued in her *Quarante Années d'études voltairiennes: bibliographie analytique des livres et articles sur Voltaire, 1926–1965* (1968). Since 1955 the Institut et Musée Voltaire, in Geneva, and the Voltaire Foundation, at the Taylor Institution in Oxford, Eng., have been publishing the multivolume series "Studies on Voltaire and the Eighteenth Century"; several works appear in the series each year, and many of the titles cited below belong to it.

Life: GUSTAVE DESNOIRESTERRES, *Voltaire et la société au XVIII siècle,* 2nd ed., 8 vol. (1871–76, reprinted 1967), is a narrative work that was the basis for most later Voltaire biographies but is outdated now because of the numerous documents discovered since its original publication; THEODORE BESTERMAN, *Voltaire,* 3rd rev. ed. (1976), offers a thorough, informed life story that is characterized by the author's full agreement with the views of Voltaire himself; IRA O. WADE, *The*

Intellectual Development of Voltaire (1969), is another broad-ranging, scholarly biography; A. OWEN ALDRIDGE, *Voltaire and the Century of Light* (1975), examines both the life and works; JOHN E.N. HEARSEY, *Voltaire* (1976), provides a highly readable introductory survey of important events of Voltaire's life; JEAN ORIEUX, *Voltaire* (1979; originally published in French, 1966), is a detailed biographical account by a French historian, written in the tradition of Desnoiresterres; PEYTON RICHTER and ILONA RICARDO, *Voltaire* (1980), is a short work that introduces the general reader to Voltaire; and HAYDN MASON, *Voltaire: A Biography* (1981), is a scholarly study that places particular emphasis on the philosopher's later years and serves as a companion to Mason's critical survey of Voltaire's work, cited below.

WAYNE ANDREWS, *Voltaire* (1981), provides a well-researched biography with a discussion of Voltaire's social and literary contacts; and JEAN MOHSEN FAHMY, *Voltaire et Paris* (1981), explores his Parisian life at different periods. Social and literary contacts and associates are studied in PAUL O. LECLERC, *Voltaire and Crébillon Père: History of an Enmity* (1973); and CHRISTIANE MERVAUD, *Voltaire et Frédéric II: une dramaturgie des lumières, 1736–1778* (1985). *Voltaire and the English* (1979) is a collection of scholarly articles, with an illustrated catalog of a documents exhibition on Voltaire's journeys and the intellectual influences stemming from them. English literary and social influences are also studied in AHMAD GUNNY, *Voltaire and English Literature* (1979). Russian influences and Voltaire's place in Russian historiography are explored in CAROLYN H. WILBERGER, *Voltaire's Russia: Window on the East* (1976). Voltaire's temperament and personality are studied in NORMAN L. TORREY, *The Spirit of Voltaire* (1938, reprinted 1968); and R.S. RIDGWAY, *Voltaire and Sensibility* (1973). NANCY MITFORD, *Voltaire in Love* (1957, reissued 1985); and SAMUEL EDWARDS, *The Divine Mistress* (1970), are substantial histories of Voltaire's involvement with Mme du Châtelet, who greatly influenced both his work and his life.

Views: RENÉ POMEAU, *La Religion de Voltaire*, rev. ed. (1969, reissued 1974), examines the religious beliefs of Voltaire within the intellectual background of the 18th century, concluding that he was indeed a deist; other studies of Voltaire's views on religion and religious matters include JOHN RENWICK, *Marmontel, Voltaire, and the Bélisaire Affair* (1974); RICHARD A. BROOKS, *Voltaire and Leibniz* (1964); WILLIAM H. TRAPNELL, *Christ and His "Associates" in Voltairian Polemic: An Assault on the Trinity and the Two Natures* (1982), and *Voltaire and the Eucharist* (1981); R.E. FLORIDA, *Voltaire and the Socinians* (1974); GRAHAM GARGETT, *Voltaire and Protestantism* (1980); DAVID D. BIEN, *The Calas Affair: Persecution, Toleration, and Heresy in Eighteenth-Century Toulouse* (1960, reprinted 1979), on Voltaire's intervention in a case of religious persecution;

and BERTRAM EUGENE SCHWARZBACH, *Voltaire's Old Testament Criticism* (1971).

For political and social views, see HENRY MEYER, *Voltaire on War and Peace* (1976); and PETER GAY, *Voltaire's Politics: The Poet as Realist,* 2nd ed. (1988), dealing with Voltaire's politics in relation to England, France, Prussia, Russia, and Geneva and relating his ideas for social reform directly to events in 18th-century Europe. A.J. AYER, *Voltaire* (1986), assesses him as a historian and dramatist, with a focus on his religious and philosophical arguments. PATRICK HENRY, *Voltaire and Camus: The Limits of Reason and the Awareness of Absurdity* (1975), is a study of Voltaire's interpretation of the philosophical categories of rationalism and absurdity.

Critical studies: VIRGIL W. TOPAZIO, *Voltaire: A Critical Study of His Major Works* (1967), analyzes the thought and work of Voltaire the storyteller, historian, playwright, and philosopher. J.H. BRUMFITT, *Voltaire, Historian* (1958, reprinted 1985), studies the principal features of his historical works and the theories behind them. Other introductions to Voltaire's criticism, analyzing selections of representative works without detailed exploration of individual ones, include THEODORE BESTERMAN, *Voltaire Essays, and Another* (1962, reprinted 1980); WILLIAM F. BOTTIGLIA (ed.), *Voltaire: A Collection of Critical Essays* (1968); R.H. HOWELLS *et al.* (eds.), *Voltaire and His World* (1985); HAYDN MASON, *Voltaire* (1975); and JEAN SAREIL (ed.), *Voltaire et la critique* (1966), a collection of essays, both in English and in French, devoted to Voltaire as poet, historian, philosopher, storyteller, and propagandist. For separate analyses, in English, of major works, see DENNIS FLETCHER, *Voltaire, Lettres Philosophiques* (1986), a brief critical guide; and GEOFFREY MURRAY, *Voltaire's Candide: The Protean Gardener, 1755–1762* (1970).

Voltaire as a playwright is studied in JACK ROCHFORD VROOMAN, *Voltaire's Theatre: The Cycle from Œdipe to Mérope* (1970); ROBERT L. HERBERT, *David, Voltaire, "Brutus," and the French Revolution* (1972), an exploration of the political atmosphere at the time of the 1790 revival of Voltaire's play *Brutus* and its role in the French Revolution; LILIAN WILLENS, *Voltaire's Comic Theatre: Composition, Conflict, and Critics* (1975); and MARIE WELLINGTON, *The Art of Voltaire's Theatre: An Exploration of Possibility* (1987). Fiction and poetry are discussed in DOUGLAS A. BONNEVILLE, *Voltaire and the Form of the Novel* (1976); JACQUES VAN DEN HEUVEL, *Voltaire dans ses contes: De "Micromégas" à "L'Ingénu,"* 3rd ed. The Technology of War

Technology may be defined as the application of knowledge to obtain a physical effect by means of an object. It may also be defined as the object itself and as the knowledge required to design, produce, and employ the object. The technology of war encompasses the entire range of weapons, equipment, structures, and vehicles with which man has armed himself specifically for the purpose of fighting his fellow man. It also includes the knowledge required to construct them, to employ them in combat, and to repair and replenish them.

The technology of war may be divided into five categories. Offensive arms harm the enemy, while defensive weapons ward off offensive blows. Transportation technology moves soldiers and weaponry; communications coordinate the movements of armed forces; and sensors detect forces and guide weaponry.

From the earliest times, a critical relationship has existed between military technology, the tactics of its employment, and the psychological factors that bind its users into units. Success in combat, the sine qua non of military organizations and the ultimate purpose of military technology, depends on the ability of the combatant group to coordinate the actions of its members in a tactically effective manner. This coordination is a function of the strength of the forces that bind the unit together, inducing its members to set aside their individual interests—even life itself—for the welfare of the group. These forces, in turn, are directly affected both by tactics and by technology.

The influence of technology can be either positive or negative. The experience of the ancient Greek hoplite infantrymen is one example of positive influence. Their arms and armour were most effective for fighting in close formation, which led in turn to marching in step, which further augmented cohesion and made the phalanx a tactically formidable formation. The late medieval knight offers an example of the negative influence of technol-

ogy. To wield his sword and lance effectively, he and his charger needed considerable space, yet his closed helmet made communication with his fellows extremely difficult. It is not surprising, then, that knights of the late Middle Ages tended to fight as individuals and were often defeated by cohesive units of less well-equipped opponents.

This article is about the physical artifacts of war, the objects used in combat and in supporting the application of military force. The article is divided into two parts. The first traces the development of military technology by historical period, from prehistory to the 18th century. The second part discusses individual weapons or weapon systems as they have been developed since the 18th century.

A full treatment of the actual waging of war—including discussions of strategy, tactics, and logistics—is found in the article WAR, THE THEORY AND CONDUCT OF. The social sciences of war, such as economics, law, and the theory of its origins, are also covered in that article. For a military history of World Wars I and II, see WORLD WARS. Accounts of other wars can be found in articles on individual countries, regions, and historical eras. For example, for the American Civil War, see UNITED STATES OF AMERICA; for the Punic Wars, see GREEK AND ROMAN CIVILIZATION, ANCIENT.

Warfare requires the use of technologies that also have nonmilitary applications. For descriptions of the propulsion systems used in military vehicles, ships, aircraft, and missiles, see ENERGY CONVERSION; for the manufacture of explosives, see INDUSTRIES, CHEMICAL PROCESS. The principles of radar, and its military applications, are covered in RADAR. For the principles of aircraft flight, see TRANSPORTATION.

For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* section 736, and the *Index.*

This article contains the following sections:

MILITARY TECHNOLOGY BEFORE THE MODERN ERA

In the remote past, the diffusion of military technology was gradual and uneven. There were several reasons for this. First, transport was slow and its capacity small. Second, the technology of agriculture was no more advanced than that of war, so that, with most of their energy devoted to feeding themselves and with little economic surplus, people had few resources available for specialized military technology. Low economic development meant that even the benefits of conquest would not pay off a heavy investment in weaponry. Third, and most important, the absolute level of technological development was low. A heavy dependence on human muscle was the principal cause and a major effect of this low level of development. With human ingenuity bound by the constraints of the human body, both technology and tactics were heavily shaped by geography, climate, and topography.

The emergence of military ecospheres

The importance of geographic and topographic factors, along with limited means of communication and transportation, meant that separate geographic regions tended to develop unique military technologies. Such areas are called military ecospheres. The boundaries of a military ecosphere might be physical barriers, such as oceans or mountain ranges; they might also be changes in the military topography, that combination of terrain, vegetation, and man-made features that could render a particular technology or tactic effective or ineffective.

Until the late 15th century AD, when advances in transportation technology broke down the barriers between them, the world contained a number of military ecospheres. The most clearly defined of these were based in Mesoamerica, Japan, India–Southeast Asia, China, and Europe. (In this context, Europe includes all of the Mediterranean basin and the watershed of the Tigris and Euphrates rivers.) With the appearance of the horse archer in late antiquity, the Eurasian Steppe became a well-defined military ecosphere as well.

Those ecospheres with the most enduring impact on the technology of war were the European and Chinese. Though Japan possessed a distinctive, coherent, and effective military technology, it had little influence on developments elsewhere. India–Southeast Asia and Mesoamerica developed technologies that were well adapted to local conditions, but they were not particularly advanced. The Eurasian Steppe was a special case: usually serving as an avenue for a limited exchange of knowledge between Europe and China, in the late classical and medieval eras of Europe it developed an indigenous military technology based on the horse and composite recurved bow that challenged Europe and ultimately conquered China.

Improved methods of transportation and warfare led to the eventual disappearance of the regional ecospheres and their absorption into the European ecosphere. This process began in the 12th century with the Mongol conquest of China and invasions of Europe, and it quickened and assumed a more pronounced European flavour in the 15th and 16th centuries with the development of oceangoing ships armed with gunpowder weapons.

Because European methods of warfare ultimately dominated the world, and because the technology of war, with few exceptions, advanced first and fastest in Europe, this article devotes most of its attention to the European military ecosphere. This first part traces the technology of land war in that ecosphere from Stone Age weapons to the early guns. For reasons of continuity, warships from before the gunpowder era are discussed with modern naval ships and craft in the second part, *Modern weapons and weapon systems.*

Prehistory

THE EARLIEST MILITARY WEAPONS

The earliest evidence for a specialized technology of war dates from the period before knowledge of metalworking had been acquired. The stone walls of Jericho, which date from about 8000 BC, represent the first technology that can be ascribed unequivocally to purely military purposes. These walls, at least 13 feet (four metres) in height and backed by a watchtower or redoubt some 28 feet tall, were clearly intended to protect the settlement and its water supply from human intruders.

When the defenses of Jericho were built, humans had used sharpened stone heads for axes, spears, and arrows for thousands of years and had no doubt mastered the use of wood for clubs, ax handles, and spear shafts. Flint daggers, first of chipped and later of polished stone, were also an established technology. Missile weapons included the simple bow, the javelin, the spear thrower, and the sling. All of these hunting tools had serious military potential, but the first known implements designed purposely as offensive weapons were maces dating from the Chalcolithic period, or early Bronze Age. The mace was a simple rock, shaped for the hand and intended to smash bone and flesh, to which a handle had been added to increase the velocity and force of the blow.

The stone mace

It is evident that the technical problems of hafting a stone onto a handle were not easily solved. Well-made maces were for a long time few in number and were, by and large, wielded only by champions and rulers. The earliest known inscription identifying a historical personage by name is on the palette of King Narmer, a small, low-relief slate sculpture dating from about 3100 BC. The palette depicts Menes, the first pharaoh of a unified Egypt, ritually smashing the forehead of an enemy with a mace.

The advent of the mace as a purposely designed offensive weapon opened the door to the conscious innovation of specialized military technology. By the middle of the 3rd millennium BC, mace heads were being cast of copper, first in Mesopotamia and then in Syria, Palestine, and Egypt. The copper mace head, yielding higher density and greater crushing power, represents one of the earliest significant uses of metal for other than ornamental purposes.

FROM PRECIOUS METALS TO BASE METALS

The dividing line between the utilitarian and the symbolic in warfare has never been clear and unequivocal, and this line is particularly difficult to find in the design and construction of early weaponry. The engineering principles that dictated functional effectiveness were not understood in any systematic fashion, yet the psychological reality of victory or defeat was starkly evident. The result was an "unscientific" approach to warfare and technology, in which materials appear to have been applied to military purposes as much for their presumed mystical or magical properties as for their functional worth.

Symbolism and utility

This overlapping of symbolism and usefulness is most evident in the smith's choice of materials. Ornaments and ceremonial artifacts aside, metalworking was applied to the production of weaponry as early as, or earlier than, any other economically significant pursuit. Precious metals, with their low melting points and great malleability, were worked first; next came copper—at first pure, then alloyed with arsenic or tin to produce bronze—and then iron. A remarkable phenomenon was the persistence of weaponry made of the soft, rare metals such as gold, silver, and electrum (a naturally occurring alloy of gold and

silver) long after mechanically superior materials had become available. Although they were functionally inferior to bronze or copper, precious metals were widely valued for their mystical or symbolic importance, and smiths continued to make weapons of them long after they had mastered the working of functionally superior base metals. Some of these weapons were plainly ceremonial, but in other cases they appear to have been functional. For example, helmets and body armour of electrum, which were probably intended for actual use, have been found in Egyptian and Mesopotamian burials dating from the 2nd and 3rd millennia BC.

Antiquity and the classical age, c. 1000 BC–AD 400

From the appearance of iron weaponry in quantity during late antiquity until the fall of Rome, the means with which war was waged and the manner in which it was conducted displayed many enduring characteristics that gave the period surprising unity. Prominent features of that unity were a continuity in the design of individual weaponry, a relative lack of change in transportation technology, and an enduring tactical dominance of heavy infantry.

Reliance on human muscle

Perhaps the strongest underlying technological feature of the period was the heavy reliance on human muscle, which retained a tactical primacy that contrasted starkly with medieval times, when the application of horse power became a prime ingredient of victory. (There were two major, if partial, exceptions to this prevailing feature: the success of horse archers in the great Eurasian Steppe during late classical times, and the decisive use in the 4th century BC of shock cavalry by the armies of Philip II of Macedon and his son Alexander the Great. However, the defeat of Roman legions by Parthian horse archers at Carrhae in western Mesopotamia in 53 BC marked merely a shifting of boundaries between ecospheres on topographical grounds rather than any fundamental change within the core of the European ecosphere itself. Also, the shock cavalry of Philip and Alexander was an exception so rare as to prove the rule; moreover, their decisiveness was made possible by the power of the Macedonian infantry phalanx.) Heavy infantry remained the dominant European military institution until it was overthrown in the 4th century AD by a system of war in which shock cavalry played the central role.

Classical technologists never developed an efficient means of applying animal traction to haulage on land, no doubt because agricultural resources in even the most advanced areas were incapable of supporting meaningful numbers of horses powerful enough to make the effort worthwhile. Carts were heavy and easily broken, and the throat-and-girth harness for horses, mules, and donkeys put pressure on the animals' windpipes and neck veins, severely restricting the amount they could pull. The yoke-and-pole harness for oxen was relatively efficient and oxen could pull heavy loads, but they were extremely slow. A human porter, on the other hand, was just as efficient as a pack horse in weight carried per unit of food consumed. The best recipe for mobility, therefore, was to restrict pack animals to the minimum needed for carrying bulky items such as essential rations, tents, and firewood, to use carts only for items such as siege engines that could be carried in no other way, and to require soldiers to carry all their personal equipment and some of their food.

On the other hand, mastery of wood and bronze for military purposes reached a level during this period that was seldom, if ever, attained afterward. Surviving patterns for the Roman military boot, the caliga, suggest equally high standards of craftsmanship in leatherworking, and the standards of carpentry displayed on classical ships were almost impossibly high when measured against those of later eras.

DEFENSIVE WEAPONRY

The design and production of individual defensive equipment was restricted by the shape of the human form that it had to protect; at the same time, it placed heavy demands on the smith's skills. The large areas to be protected,

restrictions on the weight that a combatant could carry, the difficulty of forging metal into the complex contours required, and cost all conspired to force constant change.

The technology of defensive weapons was rarely static. Evidence exists of an ancient contest between offensive and defensive weaponry, with defensive weaponry at first leading the way. By 3000 BC Mesopotamian smiths had learned to craft helmets of copper-and-arsenic bronze, which, no doubt worn with a well-padded leather lining, largely neutralized the offensive advantages of the mace. By 2500 BC the Sumerians were making helmets of bronze, along with bronze spearheads and ax blades. The weapon smiths' initial response to the helmet was to augment the crushing power of the mace by casting the head in an ellipsoidal form that concentrated more force at the point of impact. Then, as technical competence increased, the ellipsoidal head became a cutting edge, and by this process the mace evolved into the ax. The contest between mace and helmet initiated a contest between offensive and defensive technology that continued throughout history.

Competition between offensive and defensive weaponry

Helmets. The helmet, though arguably the earliest focus of the armourer's craft, was one of the most demanding challenges. Forging an integral, one-piece dome of metal capable of covering the entire head was extremely difficult. The Corinthian Greek helmet, a deep, bowl-shaped helmet of carefully graduated thickness forged from a single piece of bronze, probably represented the functional as well as aesthetic apex of the bronze worker's art. Many classical Greek helmets of bronze were joined by a seam down the crown.

Iron helmets followed the evolution of iron mail, itself a sophisticated and relatively late development. The legionnaire of the early Roman Republic wore a helmet of bronze, while his successor in the Empire of the 1st century AD wore one of iron.

Shields. Shields were used for hunting long before they were used for warfare, partly for defense and partly for concealment in stalking game, and it is likely that the military shield evolved from that of the hunter and herdsman. The size and composition of shields varied greatly, depending on the tactical demands of the user. In general, the more effective the protection afforded by body armour, the smaller the shield; similarly, the longer the reach of the soldier's weapon, the smaller his shield. The Greek hoplite, a heavy infantryman who fought in closely packed formation, acquired his name from the *hoplon*, a convex, circular shield, approximately three feet (90 centimetres) in diameter, made of composite wood and bronze (see Figure 1). It was carried on the left arm by means of a bronze strap that passed across the forearm and a rope looped around the inner rim with sufficient slack to be gripped in the fist. In the 4th century BC the soldier of the Roman Republic, who fought primarily with the spear, carried an oval shield, while the later imperial legionnaire, who closed in with a short sword, protected himself with the *scutum*, a large cylindrical shield of leather-clad wood that covered most of his body (see Figure 2).

The Greek *hoplon*

Body armour. Padded garments, and perhaps armour of hardened leather, preceded edged metal weapons. It was then a logical, if expensive, step to cast or forge small metal plates and sew them onto a protective garment. These provided real protection against arrow, spear, or mace, and the small scales, perforated for attachment, were a far less demanding technical challenge than even the simplest helmet. Armour of overlapping scales of bronze, laced together or sewn onto a backing of padded fabric, is well represented in pictorial evidence and burial items from Mesopotamia, Palestine, and Egypt from about 1500 BC, though its use was probably restricted to a small elite.

Bronze. By classical times, breastplates of bronze, at first beaten and then cast to the warrior's individual shape, were commonplace among heavy infantry and elite cavalry. Greaves, defenses for the lower leg, closely followed the breastplate. At first these were forged of bronze plates; some classical Greek examples were cast to such fine tolerances that they sprang open and could be snapped onto the calf. Defenses for more remote portions of the body, such as vambraces for the forearm and defenses for the ankle resembling spats, were included in Greek

temple dedications, but they were probably not common
in field service.

Bronze was the most common metal for body defenses
well into the Iron Age, a consequence of the fact that it
could be worked in large pieces without extended hand
forging and careful tempering, while iron had to be forged
from relatively small billets.

Mail. The first practical body armour of iron was mail,
which made its appearance in Hellenistic times but be-
came common only during the Roman Imperial period.

Figure 2: *Roman legionnaires of the 2nd century AD.*
The soldiers at top wear a segmented iron breastplate called
the *lorica segmentata*, carry a leather-covered shield called
the *scutum*, and are armed with a short iron sword called the
gladius. The soldiers at bottom put up wooden fortification—
a task at which the Romans excelled. All wear iron helmets.
Detail of Trajan's Column, Rome, AD 106–113.

(Bronze mail was impractical because of the insufficient
strength of the alloy.) Mail, or chain mail, was made of
small rings of iron, typically of one-half-inch diameter
or less, linked into a protective fabric. The rings were
fastened together in patterns of varying complexity de-
pending on the degree of protection desired; in general,
smaller, lighter rings fastened in dense, overlapping pat-
terns meant lighter, better protection. The fabrication of
mail was extremely labour-intensive. The earliest mail
was made of hand-forged links, each individual link riveted
together. Later, armourers used punches of hardened iron
to cut rings from sheets: this reduced the labour involved
and, hence, the cost.

The earliest evidence of mail is depicted on Greek sculp-
ture and friezes dating from the 3rd century BC, though
this kind of protection might be considerably older (there
was some evidence that it might be of Celtic origin). Little
else is known about the use of mail by the Greeks, but the
Roman legionnaire was equipped with a *lorica hamata,*
a mail shirt, from a very early date. Mail was extremely
flexible and provided good protection against cutting and
piercing weapons. Its main disadvantage was its weight,
which tended to hang from the shoulders and waist. In
addition, strips of mail tended to curl at the edges; the Ro-
mans solved this problem by lacing mail shoulder defenses
to leather plates. In the 1st century AD the legionnaire's   The
mail shirt gave way to a segmented iron torso defense, the   Roman
lorica segmentata.   *lorica*
Plate-iron armour. While some early forged bronze ar-   *segmentata*
mour was technically plate, the introduction of the *lorica
segmentata* heralded the production of practical plate ar-
mour on a large scale. In general, the term plate would
imply a uniform thickness of metal, and only iron could
provide reasonably effective protection with uniform thick-
ness without excessive weight.

While the Republican legionnaire's *lorica hamata* hung
to the midthigh, his imperial successor's *lorica segmen-
tata* covered only the shoulders and torso. On the whole,
classical plate armour probably provided better protec-
tion against smashing and heavy piercing blows, while a
shirt of well-made mail covered more of the body and,
hence, afforded better protection against slashing blows
and missiles.

OFFENSIVE WEAPONRY

Development of the offensive technology of war was not
as constrained by technological and economic limitations
as was defensive weaponry. Every significant offensive
weapon was widely available, while defensive equipment
of high quality was almost always confined to the elite.
Perhaps as a consequence, a wide variety of individual
offensive weapons appeared in antiquity. One of the most
striking facets of ancient military technology is the early
date by which individual weapons attained their form and
the longevity of early offensive weapons concepts. Some of
the weapons of antiquity disappeared as practical military
implements in classical and medieval times, and all under-
went modification, but, with the exception of the halberd
and crossbow, virtually every significant pre-gunpowder
weapon was known in antiquity.

The ax. Limitations on the strength of bronze and dif-
ficulties in casting and hafting restricted the ax at first to
a relatively broad blade mortised into a handle at three
points and secured with bindings or rivets. The haft-
ing problem became acute as improvements in armour
dictated longer, narrower blades designed primarily for
piercing rather than cutting. This led to the development   Socketed
of socketed axes, in which the handle passed through a   ax heads
tubular hole cast in the ax head; both hole and head were
tapered from front to rear to prevent the head from flying
off. This far stronger hafting technique must have been
accompanied by a significant improvement in the quality
of the metal itself. The pace and timing of these develop-
ments varied enormously from place to place, depending
on the local level of technology. Sumerian smiths were
casting socketed ax heads with narrow piercing blades by
2500 BC, while simple mortise-and-tenon hafting was still
being used in Egypt 1,000 years later.

The spear. Though early man probably employed spears

of fire-hardened wood, spearheads of knapped stone were used long before the emergence of any distinction between hunting and military weapons. Bronze spearheads closely followed the development of alloys hard enough to keep a cutting edge and represented, with the piercing ax, the earliest significant military application of bronze. Spearheads were also among the earliest militarily significant applications of iron, no doubt because existing patterns could be directly extrapolated from bronze to iron. Though the hafting is quite different, bronze Sumerian spearheads of the 3rd millennium BC differ only marginally in shape from the leaf-shaped spearheads of classical Greece.

The spears of antiquity were relatively short, commonly less than the height of the warrior, and typically were wielded with one hand. As defensive armour and other weapons of shock combat (notably the sword) improved, spear shafts were made longer and the use of the spear became more specialized. The Greek hoplite's spear was about nine feet long; the Macedonian *sarissa* was twice that length in the period of Alexander's conquests and it grew to some 21 feet in Hellenistic times.

The javelin.   Javelins, or throwing spears, were shorter and lighter than spears designed for shock combat and had smaller heads. The distinction between javelin and spear was slow to develop, but by classical times the heavy spear was clearly distinguished from the javelin, and specialized javelin troops were commonly used for skirmishing. A throwing string was sometimes looped around the shaft and tied to the thrower's finger to impart spin to the javelin on release. This improved the weapon's accuracy and probably increased the range and penetrating power by permitting a harder cast.

A significant refinement of the javelin was the Roman pilum. The pilum was relatively short, about five feet long, and had a heavy head of soft iron that made up nearly one-third of the weapon's total length. The weight of this weapon restricted its range but gave it greater impact. Its head of soft iron was intended to bend on impact, preventing an enemy from throwing it back.

Like the spear, the javelin was relatively unaffected by the appearance of iron and retained its characteristic form until it was finally abandoned as a serious weapon in the 16th century.

The sling.   The sling was the simplest of the missile weapons of antiquity in principle and the most difficult in practice. It consisted of two cords or thongs fastened to a pouch. A small stone was placed in the pouch, and the slinger whirled the whole affair around to build up velocity before letting go of one of the cord ends to release the projectile. While considerable velocity could be imparted to a projectile in this way, the geometry of the scheme dictated that the release be timed with uncanny precision to achieve even rudimentary accuracy. Almost always wielded by tribal or regionally recruited specialists who acquired their skills in youth, the sling featured prominently in warfare in antiquity and classical times. It outranged the javelin and even—at least at some times and places—the bow (a point confirmed in the 4th century BC by the Greek historian Xenophon). By classical times, lead bullets, often with slogans or epigrams cast into them—"A nasty present!"—were used as projectiles.

The sling vanished as a weapon of war in the Old World by the end of the classical period, owing mainly to the disappearance of the tribal cultures in which it originated. (In the New World, on the other hand, both the Aztecs and Incas used the sling with great effect against Spanish conquistadores in the 16th century.)

The sword.   The advantages of a long, sharp blade had to await advanced smelting and casting technology before they could be realized. By about 1500 BC the cutting ax had evolved into the sickle sword, a bronze sword with a curved, concave blade and a straight, thickened handle. Bronze swords with straight blades more than three feet long have been found in Greek grave sites; however, because this length exceeded the structural capabilities of bronze, these swords were not practical weapons. As a serious military implement, the sword had to await the development of iron forging, and the first true swords date from about 1200 BC.

Swords in antiquity and classical times tended to be relatively short, at first because they were made of bronze and later because they were rarely called upon to penetrate iron armour. The blade of the classic Roman stabbing sword, the *gladius,* was only some two feet long, though in the twilight years of the empire the *gladius* gave way to the spatha, the long slashing sword of the barbarians.

<div style="float:right">The Roman *gladius*</div>

The bow.   The bow was simple in concept, yet it represented an extremely sophisticated technology. In its most basic form, the bow consisted of a stave of wood slightly bent by the tension of a bowstring connecting its two ends. The bow stored the force of the archer's draw as potential energy, then transferred it to the bowstring as kinetic energy, imparting velocity and killing power to the arrow. The bow could store no more energy than the archer was capable of producing in a single movement of the muscles of his back and arms, but it released the stored energy at a higher velocity, thus overcoming the arm's inherent limitations.

Though not as evident, the sophistication of arrow technology matched that of the bow. The effectiveness of the bow depended on the arrow's efficiency in retaining kinetic energy throughout its trajectory and then transforming it into killing power on impact. This was not a simple problem, as it depended on the mass, aerodynamic drag, and stability of the arrow and on the hardness and shape of the head. These factors were related to one another and to the characteristics of the bow in a complex calculus. The most important variables in this calculus were arrow weight and the length and stiffness of the bow.

Assuming the same length of draw and available force, the total amount of potential energy that an archer could store in a bow was a function of the bow's length; that is, the longer the arms of the bow, the more energy stored per unit of work expended in the draw and, therefore, the more kinetic energy imparted to the string and arrow. The disadvantage of a long bow was that the stored energy had to serve not only to drive the string and arrow but also to accelerate the mass of the bow itself. Because the longer bow's more massive arms accelerated more slowly, a longer bow imparted kinetic energy to the string and arrow at a lower velocity. A shorter bow, on the other hand, stored less energy for the same amount of work expended in the draw, but it compensated for this through its ability to transmit the energy to the arrow at a higher velocity. In sum, the shorter bow imparted less total energy to the arrow, but it did so at a higher velocity. Therefore, in practice maximum range was attained by a short, stiff bow shooting a very light arrow, and maximum killing power at medium ranges was attained by a long bow driving a relatively heavy arrow.

<div style="float:right">Tactical advantages of short and long bows</div>

The early bow.   The simple bow, made from a single piece of wood, was known to Neolithic hunters; it is clearly depicted in cave paintings of 30,000 BC and earlier. The first improvement was the reflex bow, a bow that was curved forward, or reflexively, near its centre so that the string lay close against the grip before the bow was drawn. This increased the effective length of the draw since it began farther forward, close to the archer's left hand.

The composite recurved bow.   The next major improvement, one that was to remain preeminent among missile weapons until well into the modern era, was the composite recurved bow. This development overcame the inherent limitations of wood in stiffness and tensile strength. The composite bow's resistance to bending was increased by reinforcing the rear, or belly, of the bow with horn; its speed and power in recoil were increased by overlaying the front of the bow with sinew, usually applied under tension. The wooden structure of this composite thus consisted of little more than thin wooden strips supporting the horn and sinew. The more powerful composite bows, being very highly stressed, reversed their curvature when unstrung. They acquired the name recurved since the outer arms of the bow curved away from the archer when the bow was strung, which imparted a mechanical advantage at the end of the draw. Monumental and artistic evidence suggest that the principle of the composite recurved bow was known as early as 3000 BC.

A prime advantage of the composite bow was that it

could be engineered to essentially any desired strength. By following the elaborate but empirically understood trade-off between length and stiffness referred to above, the bowyer could produce a short bow capable of propelling light arrows to long ranges, a long, heavy bow designed to maximize penetrative power at relatively short ranges, or any desired compromise between.

Arrows. Arrow design was probably the first area of military technology in which production considerations assumed overriding importance. As a semi-expendable munition that was used in quantity, arrows could not be evaluated solely by their technological effectiveness; production costs had to be considered as well. As a consequence, the materials used for arrowheads tended to be a step behind those used for other offensive technologies. Arrowheads of flint and obsidian, knapped to remarkably uniform standards, survived well into the Bronze Age, and bronze arrowheads were used long after the adoption of iron for virtually every other military cutting or piercing implement.

Arrow shafts were made of relatively inexpensive wood and reed throughout history, though considerable labour was involved in shaping them. Remarkably refined techniques for fastening arrowheads of flint and obsidian to shafts were well in hand long before recorded history. (The importance of arrow manufacturing techniques is reflected in the survival in modern English of the given name Fletcher, the title of a specialist in attaching feathers to the arrow shaft.)

MECHANICAL ARTILLERY

In contrast to individual weaponry, there was little continuity from classical to medieval times in mechanical artillery. The only exception—and it may have been a case of independent reinvention—was the similarity of the Roman onager to the medieval catapult.

Tension-driven *gastrophetes* and torsion-driven catapult

Mechanical artillery of classical times was of two types: tension and torsion. In the first, energy to drive the projectile was provided by the tension of a drawn bow; in the other, it was provided by torsional energy stored in bundles of twisted fibres.

The invention of mechanical artillery was ascribed traditionally to the initiative of Dionysius the Elder, tyrant of Syracuse, in Sicily, who in 399 BC directed his engineers to construct military engines in preparation for war with Carthage. Dionysius' engineers surely drew on existing practice. The earliest of the Greek engines was the *gastrophetes,* or "belly shooter." In effect a large crossbow, it received its name because the user braced the stock against his belly to draw the weapon. Though Greek texts did not go into detail on construction of the bow, it was based on a composite bow of wood, horn, and sinew. The potential of such engines was apparent, and the demand for greater power and range quickly exceeded the capabilities of tension. By the middle of the 3rd century BC, the bow had been replaced by rigid wooden arms constrained in a wooden box and drawn against the force of tightly twisted bundles of hair or sinew. The overall concept was similar to the *gastrophetes,* but the substitution of torsion for tension permitted larger and more powerful engines to be made. Such catapults (from Greek *kata,* "to pierce," and *pelte,* "shield"; a "shield piercer") could throw a javelin as far as 800 yards (700 metres). The same basic principle was applied to large stone-throwing engines. The Jewish historian Josephus referred to Roman catapults used in the siege of Jerusalem in AD 70 that could throw a one-talent stone (about 55 pounds, or 25 kilograms) two *stades* (400 yards) or more.

The terminology of mechanical artillery is confusing. Catapult is the general term for mechanical artillery; however, the term also narrowly applies to a particular type of torsion engine with a single arm rotating in a vertical plane. Torsion engines with two horizontally opposed arms rotating in the horizontal plane, such as that described above, are called ballistae. There is no evidence that catapults in the narrow sense were used by the Greeks; the Romans called their catapults onagers, or wild asses, for the way in which their rears kicked upward under the recoil force. The Romans used large ballistae and onagers effectively in siege operations, and a complement of *carroballistae,* small, wheel-mounted torsion engines, was a regular part of the legion. The onager and the medieval catapult were identical in concept, but ballistae were not used after the classical era.

FORTIFICATION

Fortress design. Fortifications in antiquity were designed primarily to defeat attempts at escalade, though cover was provided for archers and javelin throwers along the ramparts and for enfilade fire from flanking towers. By classical Greek times, fortress architecture had attained a high level of sophistication; both the profile and trace (that is, the height above ground level and the outline of the walls) of fortifications were designed to achieve overlapping fields of fire from ballistae mounted along the ramparts and in supporting towers. Roman fortresses of the 2nd century AD, largely designed for logistic and administrative convenience, tended to have square or rectangular outlines, and were situated along major communication routes. By the late 3rd century, their walls had become thicker and had flanking towers strengthened to support mechanical artillery. The number of gates was reduced, and the ditches were dug wider. By the late 4th and 5th centuries, Roman fortresses were being built on easily defensible ground with irregular outlines that conformed to the topography; clearly, passive defense had become the dominant design consideration.

Roman fortress design

In general, the quality of masonry that went into permanent defensive works of the classical period was very high by later standards. Fortifications were almost exclusively of dressed stone, though by Roman times concrete mortar was used on occasion.

Field fortification. The main purpose of early field fortifications, particularly among the Greeks, was to secure an advantage by standing on higher ground so that the enemy was forced to attack uphill. The Romans were especially adept at field fortifications, preparing fortified camps at the close of each day's march (see Figure 2). The troops usually required three to four hours to dig a ditch around the periphery, erect a rampart or palisade from timbers carried by each man, lay out streets, and pitch tents. During extended campaigns the Romans strengthened the camps with towers and outlying redoubts, or small forts, and used the camps as bases for offensive forays into the surrounding territory.

Siege towers. For breaching fortified positions, military engineers of the classical age designed assault towers that remain a wonder to modern engineers. So large was one siege tower used by Macedonians in an attack on Rhodes that 3,400 men were required to move it up to the city walls. Another 1,000 men were needed to wield a battering ram 180 feet (55 metres) long. The Romans constructed huge siege towers, one of which Caesar mentions as being 150 feet high. The lower stories housed the battering ram, which had either a pointed head for breaching or a ram-like head for battering. Archers in the upper stories shot arrows to drive the defenders from their ramparts. From the top of the tower, a hinged bridge might be lowered to serve a storming party. To guard the attackers against enemy missiles, the Romans used great wicker or wooden shields, called mantelets, which were sometimes mounted on wheels. In some cases the attackers might approach the fortress under the protection of wooden galleries.

LAND TRANSPORTATION

In antiquity and classical times the transportation technology of land warfare largely amounted to man's own powers of locomotion. This was due in part to limitations in the size, strength, and stamina of horses and in part to deficiencies in crucial supporting technologies, notably the inefficiency of harnesses for horses and nonpivoting front axles for wagons. A more basic underlying factor was the generally low level of economic development. The horse was an economically inefficient animal, consuming large quantities of food. Of more importance, keeping horses—let alone selectively breeding them for size, strength, and power—was a highly labour-intensive and capital-intensive enterprise for which the classical world was not organized.

The expense of horse-drawn transport

An efficient pulling harness for horses was unknown, and mules and donkeys fitted with carrying baskets, or panniers, balanced in pairs across the back, were the most common pack or dray animals. The ox, the heavy-duty dray animal of the Mediterranean world, was used for military purposes when heavy loads were involved and speed was not critical.

The horse. Because it was not possible to maintain a breed of war-horses sufficiently powerful to sustain mounted shock action, the horse was restricted to a subsidiary role in warfare from the eclipse of the chariot in the middle of the 2nd millennium BC until the rise of the horse archer in the 4th century AD. Evidence as to the size of horses in classical times is equivocal. Greek vase paintings from the 7th century BC depict Scythians riding tall, apparently powerful horses with long, slender legs, implying speed; however, this breed evidently collapsed and disappeared. Later Mongolian steppe ponies, though tough and tractable, were probably considerably smaller.

Horses were rarely if ever used for drayage. This was partly because their rarity and expense restricted them to combat roles, and partly because of the lack of a suitable harness. The prevalent harness consisted of a pole-and-yoke assembly, attached to the animal by neck and chest harness. This was developed for use with oxen, where the primary load was absorbed by the thrust of the animal's hump against the yoke. With a horse, most of the pulling load was borne by the neck strap, which tended to strangle the horse and constrict blood flow.

The elephant. The war elephant was first used in India and was known to the Persians by the 4th century BC. Though they accomplished little subsequently, their presence in Hannibal's army during its transit of the Alps into Italy in 218 BC underscored their perceived utility. The elephant's tactical importance apparently stemmed in large part from its willingness to charge both men and horses and from the panic that it inspired in horses.

The chariot. The chariot was the earliest means of transportation in combat other than man's own powers Chariots of the of locomotion. The earliest known chariots, shown in ancient Middle Sumerian depictions from about 2500 BC, were not true East chariots but four-wheeled carts with solid wooden wheels drawn by a team of four donkeys or wild asses. They were no doubt heavy and cumbersome; lacking a pivoting front axle, they would have skidded through turns.

Around 1600 BC Iranian tribes introduced the war-horse into Mesopotamia from the north, along with the light two-wheeled chariot. The Hyksos apparently introduced the chariot into Egypt shortly thereafter, by which time it was a mature technology. By the middle of the 2nd millennium BC, Egyptian, Hittite, and Palestinian chariots were extraordinarily light and flexible vehicles, the wheels and tires in particular exhibiting great sophistication in design and fabrication. Light war chariots were drawn by either two or three horses, which were harnessed by means of chest girths secured by one or two poles and a yoke.

That horses were long used for pulling chariots rather than for riding is probably attributable to the horse's inadequate strength and incomplete domestication. The chariot was subject to mechanical failure and, more importantly, was immobilized when any one of its horses was incapacitated. Moreover, the art of riding astride in cavalry fashion had been mastered long before the chariot's eclipse as a tactically dominant weapon. The decline of the chariot by the end of the 2nd millennium BC was probably related to the spread of iron weaponry, but it was surely related also to the breeding of horses with sufficient strength and stamina to carry an armed man. Chariots lingered in areas of slower technological advance, but in the classical world they were retained mainly for ceremonial functions.

The age of cavalry, c. AD 400–1350

The beginning of the age of cavalry in Europe is traditionally dated to the destruction of the legions of the Roman emperor Valens by Gothic horsemen at the Battle of Adrianople in AD 378. The period that followed, characterized by the network of political and economic relationships called feudalism, was an age during which

the mounted arm assumed an ascendancy that it began to relinquish only in the 14th century, with the appearance of infantry capable of taking the open field unsupported against mounted chivalry. Cavalry, however, was only part of the story of this era. However impressive the mounted knight may have been in battle, he required a secure place of replenishment and refuge. This was provided by the seigneurial fortress, or castle. In a military sense, European feudalism rested on a symbiotic relationship between armoured man-at-arms, war-horse, and castle.

The tactical dominance in Europe of the heavy mounted Economic elites had a number of complex causes. It is clear that a base of the basic reorientation of the means of production and of the cavalry social distribution of the means of armed violence was elite involved. Horses required large quantities of grain, and in an agricultural economy where returns on seed grain were as little as 2 to 1, mounted shock action could not have solidified its dominance without improvements in agricultural production. Perhaps ironically, these improvements seem to have involved the development of a means of harnessing the horse to agricultural transport and the plow—particularly beginning in the 14th century, when seed-to-yield ratios began to improve.

The age of heavy shock cavalry did not come on suddenly, ushered in by the stirrup or any other single invention. Improvements in the breeding of war-horses played a major and perhaps dominant role. The Germanic tribes that pressed against the boundaries of Rome from the 3rd century on may have made a breakthrough in horse breeding, and, in the Arab conquests of the 7th century and following, the superior breed of the Arabian horse was a major determinant of tactical success. The stirrup alone meant little without powerful war-horses and supporting technologies such as saddle, girth, and bridle.

Using scattered artistic and archaeological evidence, historians have constructed an approximate chronology of technological innovation in medieval Europe. The war saddle with a single girth was introduced by the 6th century, and the iron stirrup was common by the 7th (having probably been known earlier in the East). The curb bit, vitally important for controlling a war-horse, probably dates from about the same time. According to literary evidence, iron horseshoes date from the end of the 9th century, and, based on pictorial evidence, spurs date from the 11th. By the 12th century the European knight was using a war saddle with high, wraparound cantle and pommel that protected the genitals and held him securely in his seat; the saddle itself was secured to the horse by a double girth that held it firmly in place fore and aft. These developments welded horse and rider into a single unit and enabled the knight to apply much of the force of his horse's charge to the point of the lance, held couched beneath the arm, without being driven over the horse's rump on impact. An associated development dating from the end of the 12th century was the incorporation of a rigid backplate into knightly armour; this, backed with several inches of padding, braced the man-at-arms against the shock of head-on impact and protected his kidneys from the cantle. These developments were accompanied, and in part caused, by increases in the size and power of war-horses and steady improvements in personal armour.

THE WAR-HORSE

The destrier, or medieval war-horse, was central to the tactical viability of European feudalism. This animal was a product of two great migrations of horses originating in Central Asia. One, moving westward, crossed into Europe and there originated the vast herds of primeval animals that eventually roamed almost the entire continent. The second flowed to the southwest and found its way into Asia Minor and the neighbouring lands of Persia, India, and Arabia. Ultimately it crossed into Egypt, then spread from that country along all of North Africa. At the same time it crossed from Asia Minor into Greece and spread along the northern shores of the Mediterranean.

There were two channels through which the horses of Arabia and North Africa were distributed into northern Europe. One was through the conquest of the Romans across the Alps into France and the Low Countries, where,

previously, descendants of the horses of Central Asia had constituted the equine population. The other channel led northward through Greece, Macedonia, and the Gothic countries into the land of the Vandals. When these barbarian peoples invaded the empire, the vast number of horses that they possessed helped them to overthrow the Romans. The era that followed witnessed the collapse of the Roman breeds and the gradual development—especially during the era of Charlemagne in the late 8th and early 9th centuries—of improved types, owing largely to the importation of Arabian stock. The most important of these was the "great horse," which originated in the Low Countries; its size and strength were required to carry the heavy load of the armoured knight. These horses, the ancestors of modern draft breeds, were bred from the largest and most powerful of the northern European horses, but there was apparently an admixture of Arabian breeds as well.

The Crusades of the 12th and 13th centuries took the nobility of Europe into the native land of the Arabian horse. The speed and agility of these light horses so impressed them that large numbers were imported into England and France. Over a long period of time the Moors took Arabian and North African horses into Spain, where they were crossed with the native stock and produced the superior breeds that were sought after by other nations. (Spanish horses were also taken to the New World, where they became the principal ancestors of the equine population of North and South America.)

Difficulties in breeding and training horses

The breeding, care, and maintenance of medieval warhorses, and the mastering of the skills of mounted combat, required immense amounts of time, skill, and resources. Horses strong enough to be ridden did not exist everywhere, and European horses in particular tended to revert in a feral state to a small animal not much larger than a Shetland pony. On the other hand, the horse was genetically tractable, and breeders learned that hard inbreeding could produce larger, more powerful animals. Still, it was difficult to establish a breed, and only careful control of bloodlines could maintain one. While crossbreeding could produce size and power, it also promoted instability and was best abandoned as soon as the desired traits were "fixed." This was not easy, particularly where the resources available to maintain a nonproductive breeding stock were limited. The net result was that breeds of large, powerful horses suitable for mounted combat were difficult to establish and expensive to maintain, and they were often lost in the turmoil of war. Even when herds were not dispersed or destroyed, a breed could be lost through indiscriminate breeding arising from a need for numbers.

PERSONAL ARMOUR

Mail. The availability to mounted warrior elites of iron armour of high quality, particularly mail, was instrumental in the fall of Rome and in the establishment of European feudalism. Until the 10th century, however, there was little qualitative difference between the body armour of the western European knight and that of the Roman legionnaire's *lorica hamata*. Then, during the 11th century, the sleeves of the knight's mail shirt, or byrnie, became longer and closer-fitting, extending downward from the middle of the upper arm to the wrist; at the same time, the hem of the byrnie dropped from just above to just below the kneecap. Knights began wearing the gambeson, a quilted garment of leather or canvas, beneath their mail for additional protection and to cushion the shock of blows. (Ordinary soldiers often wore a gambeson as their only protection.) Use of the surcoat, a light garment worn over the knight's armour, became general during this period. Both gambeson and surcoat may have been Arab imports, adopted as a result of exposure to Muslim technology during the Crusades.

The mail hauberk

Norman men-at-arms were protected by a knee-length mail shirt called a hauberk, which was a later version of the Saxon byrnie that was split to permit the wearer to sit astride his horse (see Figure 3). Though 11th-century men-at-arms probably did not have complete mail trousers, the hauberk apparently had inserts of cloth or leather, giving the same effect. It also included a hoodlike garment of

mail worn over the head to protect the neck and throat; this had a hole for the face much like a modern ski cap. The hood was backed by padding of cloth or leather, and a pointed iron helmet with nasal (a vertical bar protecting the nose) was worn over it. The knight's defensive equipment was completed by a large, kite-shaped shield, nearly two-thirds the height of its owner. The size of this shield was testimony to the incomplete protection offered by the hauberk.

The British Library

Figure 3: *Crusader in iron mail.*
The mail shirt, or hauberk, is split below the waist for easier riding on horseback. Beneath the hauberk is a padded garment called the gambeson, and over it is worn the surcoat. The iron helm is pierced by slits for seeing and breathing. From the Westminster Psalter, 12th century. In the British Library (Royal MS. 2A xxii, fol. 220).

During the 12th century the open helmet with nasal evolved into the pot helm, or casque. This was an involved process, with the crown of the helmet losing its pointed shape to become flat and the nasal expanding to cover the entire face except for small vision slits and breathing holes. The late 12th-century helm was typically a barrel-shaped affair; however, more sophisticated designs with hinged visors appeared as well. The helm was extremely heavy, and the entire weight was borne by the neck; for this reason it was only donned immediately before combat. Some knights preferred a mail coif, no doubt with heavy padding and perhaps an iron cap beneath. One 12th-century depiction shows an iron visor worn over a coif of mail.

By the early 13th century European armourers had learned to make mail with a sufficiently fine mesh to provide protection to the hand. At first this was in the form of mittens with a leather-lined hole in the palm through which the knight could thrust his hand when out of action; by mid-century the armourer's skill had developed to the point of making complete gloves of mail.

Plate. The earliest knightly plate armour appeared shortly after 1200 in the form of thin plates worn beneath the gambeson. External plate armour began to appear around the middle of the century, at first for elbows, kneecaps, and shins. The true plate cuirass appeared about 1250, though it was at first unwieldy, covering only the front of the torso and no doubt placing considerable stress on the underlying garments to which it was attached. Perhaps in part for this reason, the breastplate was followed shortly by the backplate. From the late 13th century,

plate protection spread from the knees and elbows to encompass the extremities; square plates called ailettes, which protected the shoulder, made a brief appearance between about 1290 and 1325 before giving way to jointed plate defenses that covered the gap between breastplate and upper-arm defenses. Helmets with hinged visors appeared about 1300, and by mid-century armourers were constructing closed, visored helms that rested directly on the shoulder defenses. Plate armour, at first worn above mail as reinforcement, began to replace it entirely except in areas such as the crotch, the armpits, and the back of the knees, where the armourer's skill could not devise a sufficiently flexible joint. In response to this enhanced coverage, the knight's large, kite-shaped shield evolved into a much smaller implement.

Gothic
plate
armour

The first suits of full plate armour date from the first decades of the 15th century. By 1440 the Gothic style of plate armour was well developed, representing the ultimate development of personal armour protection (see Figure 4). Armourers were making gloves with individually jointed fingers, and shoulder defenses had become particularly sophisticated, permitting the man-at-arms full freedom to wield sword, lance, or mace with a minimum of exposure. Also during the 15th century the weight of personal armour increased, partly because of the importance of shock tactics in European warfare and partly because of the demands of jousting, a form of mock combat in which two armoured knights, separated by a low fence or barrier, rode at each other head-on and attempted to unseat each other with blunted lances. As armour protection became more complete and heavier, larger breeds of horses appeared. Mail protection for horses became common in the 13th century; by the 15th, plate horse armour was used extensively.

Figure 4: *Gothic-style armour for man and horse.*
Made at Landshut, Bavaria, about 1480, this armour represented the high point of armourers' art, but within a century the crossbow bolt and harquebus ball made full plate armour obsolete. In the Wallace Collection, London.

The unprecedented protection that plate armour gave the man-at-arms did not come without tactical, as well as economic, cost. A closed helm seriously interfered with vision and made voice communication in battle impossible. No doubt in response to this, heraldry emerged during this period and the armorial surcoat became a standard item of knightly dress. Ultimately, the thickness of iron needed to stop missiles—at first arrows and crossbow bolts, then harquebus and musket balls—made armour so heavy as to be impractical for active service. By the 16th century,

armour was largely ceremonial and decorative, with increasingly elaborate ornamentation.

THE CASTLE

The motte-and-bailey castle. The earliest distinctive European fortification characteristic of feudal patterns of social organization and warfare was the motte-and-bailey castle, which appeared in the 10th and 11th centuries between the Rhine and Loire rivers and eventually spread to most of western Europe. The motte-and-bailey castle consisted of an elevated mound of earth, called the motte, which was crowned with a timber palisade and surrounded by a defensive ditch that also separated the motte from a palisaded outer compound, called the bailey. Access to the motte was by means of an elevated bridge across the ditch from the bailey. The earliest motte-and-bailey castles were built where the ground was suitable and timber available, these factors apparently taking precedence over considerations such as proximity to arable land or trade routes. Later on, as feudal social and economic relationships became more entrenched, castles were sited more for economic, tactical, and strategic advantage and were built of imported stone. The timber palisade was replaced with a keep, or donjon, of dressed stone, and the entire enclosure, called the enceinte, was surrounded by a wall.

The motte-and-bailey castle was not the only pattern of European fortification. There was, for example, a tradition of fortified towns, stemming from Roman fortification, that enjoyed a tenuous existence throughout the Dark Ages, particularly in the Mediterranean world.

Stone fortifications. The greatest weakness of timber fortifications was vulnerability to fire; in addition, a determined attacker, given enough archers to achieve fire dominance over the palisade, could quickly chop his way in. A stone curtain wall, on the other hand, had none of these deficiencies. It could be made high enough to frustrate improvised escalade and, unlike a wooden palisade, could be fitted with a parapet and crenellated firing positions along the top to give cover to defending archers and crossbowmen (see Figure 5). Stone required little maintenance or upkeep, and it suffered by comparison with timber only in the high capital investment required to build with it.

The stone
curtain
wall

Given walls high enough to defeat casual escalade, the prime threats to stone fortresses were the battering ram and attempts to pry chunks out of the wall or undermine it. Since these tactics benefited from an unprotected footing at the base of the wall, most of the refinements of medieval fortress architecture were intended to deny an undisturbed approach. Where terrain permitted, a moat was dug around the enceinte. Towers were made with massive, protruding feet to frustrate attempts at mining. Protruding towers also enabled defenders to bring flanking fire along the face and foot of the wall, and the towers were made higher than the wall to give additional range to archers and crossbowmen. The walls themselves were fitted with provisions for hoardings, which were overhanging wooden galleries from which arrows, stones, and unpleasant substances such as boiling tar and pitch could be dropped or poured on an attacker. Hoardings gave way to machicolations, permanent overhanging galleries of stone that became a distinctive feature of medieval European fortress architecture.

Castle entrances, which were few and small to begin with, were protected by barbicans, low-lying outworks dominated by the walls and towers behind. Gates were generally deeply recessed and backed by a portcullis, a latticework grate suspended in a slot that could be dropped quickly to prevent surprise entry. The gate could also be sealed by means of a drawbridge. These measures were sufficiently effective that medieval sieges were settled more often by treachery, starvation, or disease than by breached walls and undermined towers.

SIEGE WEAPONS

The most basic means of taking a fortress were to storm the gate or go over the wall by simple escalade using ladders, but these methods rarely succeeded except by surprise or treachery. Beginning in the 9th century, European engineers constructed wheeled wooden siege towers, called
Figure 5: *Engines of medieval siegecraft.*
(Left) A siege tower, or belfroy, has been brought to the castle wall, and a storming party
crosses the drawbridge under cover from archers. (Right) Soldiers winch down the arm of
a trebuchet. Large trebuchets, powered by 10-ton counterweights, could hurl 300-pound
wall-smashing boulders as far as 300 yards.
Ian V Hogg

belfroys. These were fitted with drawbridges, which could be dropped onto the parapet, and with protected firing positions from which the defending parapets could be swept by arrow fire (see Figure 5). Constructing one of these towers and moving it forward against an active defense was a considerable feat of engineering and arms. Typically, the moat had to be filled and leveled, all under defensive fire, and attempts to burn or dismount the tower had to be prevented. The wooden towers were vulnerable to fire, so that their faces were generally covered with hides.

Battering rams were capable of bringing down sections of wall, given sufficient time, manpower, and determination. Large battering rams were mounted on wheels and were covered by a mobile shed for protection from defensive fire.

Mining castle walls   The most powerful method of direct attack on the structure of a fortress was mining, digging a gallery beneath the walls and supporting the gallery with wooden shoring. Once completed, the mine was fired to burn away the shoring; this collapsed the gallery and brought down the walls. Mining, of course, required suitable ground and was susceptible to countermining by an alert defender.

The trebuchet.   In general, the mechanical artillery of medieval times was inferior to that of the Classical world. The one exception was the trebuchet, an engine worked by counterpoise. Counterpoise engines appeared in the 12th century and largely replaced torsion engines by the middle of the 13th. The trebuchet worked something like a seesaw. Suspended from an elevated wooden frame, the arm of the trebuchet pivoted from a point about one-quarter of the way down its length. A large weight, or counterpoise, was suspended from the short end, and the long end was fitted with a hollowed-out spoonlike cavity or a sling. (A sling added substantially to the trebuchet's range.) The long end was winched down, raising the counterpoise; a stone or other missile was put into the spoon or sling, and the arm was released to fly upward, hurling the missile in a high, looping arc toward its target. Though almost anything could be thrown, spherical projectiles of cut stone were the preferred ammunition (see Figure 5).

Trebuchets might have a fixed counterpoise, a pivoted counterpoise, or a counterpoise that could be slid up and down the arm to adjust for range. Ropes were frequently attached to the counterpoise to be pulled on for extra power. Modern experiments suggest that a trebuchet with an arm about 50 feet (15 metres) long would have been capable of throwing a 300-pound (135-kilogram) stone to a distance of 300 yards (275 metres); such a trebuchet would have had a counterpoise of about 10 tons. Though the rate of fire was slow, and prodigious quantities of timber and labour were required to build and serve one, a large trebuchet could do serious damage to stone fortifications. The machines were apparently quite accurate, and small trebuchets were useful in sweeping parapets of archers and crossbowmen.

Greek fire.   Greek fire was a weapon that had a decisive tactical and strategic impact in the defense of the Byzantine Empire. It was first used against the Arabs at the siege of Constantinople of 673. Greek fire was a liquid that ignited on contact with seawater. It was viscous and burned fiercely, even in water. Sand and—according to legend—urine were the only effective means of extinguishing the flames. It was expelled by a pumplike device similar to a 19th-century hand-pumped fire engine, and it may also have been thrown from catapults in breakable containers. Although the exact ingredients of Greek fire were a Byzantine state secret, other powers eventually developed and used similar compositions. The original formula was lost and remains unknown. The most likely ingredients were colloidal suspensions of metallic sodium, lithium, or potassium—or perhaps quicklime—in a petroleum base.

Greek fire was particularly effective in naval combat, and it constituted one of the few incendiary weapons of warfare afloat that were used effectively without backfiring on their users. It may have been used following the sack of Constantinople by Venetian-supported crusaders in 1204, but it probably disappeared from use after the fall of Constantinople to the Turks in 1453.

The age of cavalry came to be viewed from a European perspective, since it was there that infantry was overthrown and there that the greatest and most far-reaching changes occurred. But it was by no means an exclusively European phenomenon; to the contrary, the mounted warrior's tactical supremacy was less complete in western Europe than in any other region of comparably advanced technology save Japan, where a strikingly parallel feudal situation prevailed. Indeed, from the 1st century AD nomadic horse archers had strengthened their hold over the Eurasian Steppes, the Iranian plateau, and the edges of the Fertile Crescent, and, in a series of waves extending

Mounted warfare in Eurasia

through medieval times, they entered Europe, China, and India and even touched Japan briefly in the 13th century. The most important of these incursions into the European and Chinese military ecospheres left notable marks on the military technology of East Asia and the Byzantine Empire, as well as on the kingdoms of Europe.

The Huns and Avars. The first of the major horse no-mad incursions into Europe were the Hunnish invasions of the 4th century. The Huns' primary significance in the history of military technology was in expanding the use of the composite recurved bow into the eastern Roman Em-pire. This important instance of technological borrowing constituted one of the few times in which a traditional mil-itary skill as physiologically and economically demanding as composite archery was successfully transplanted out of its original cultural context.

The Avars of the 6th and 7th centuries were familiar with the stirrup, and they may have introduced it into Europe. Some of the earliest unequivocal evidence of the use of the stirrup comes from Avar graves.

The Byzantine cataphract. Although they continued to make effective use of both shock and missile infantry, the Byzantines turned to cavalry earlier and more completely than did the western Roman Empire. After an extended period of dependence on Teutonic and Hunnish mercen-ary cavalry, the reforms of the emperors Maurice and Heraclius in the 6th and 7th centuries developed an effec-tive provincial militia based on the institution of *pronoia,* the award of nonhereditary grants of land capable of supporting an armoured horse archer called a cataphract. *Pronoia,* which formed the core of the Byzantine army's strength during the period of its greatest efficiency in the 8th through 10th centuries, entailed the adoption of the Hunnish composite recurved bow by native troopers.

The Byzantine cataphract was armed with bow, lance, sword, and dagger; he wore a shirt of mail or scale armour and an iron helm and carried a small, round, ironbound shield of wood that could be strapped to the forearm or slung from the waist. The foreheads and breasts of officers' horses and those of men in the front rank were protected with frontlets and poitrels of iron. The militia cataphracts were backed by units of similarly armed regulars and mer-cenary regiments of Teutonic heavy shock cavalry of the imperial guard. Mercenary horse archers from the steppe continued to be used as light cavalry.

The Turks. The infiltration of Turkish tribes into the Eurasian military ecosphere was distinguished from earlier steppe nomad invasions in that the raiders were absorbed culturally through Islāmization. The long-term results of this wave of nomadic horse archers were profound, lead-ing to the extinction of the Byzantine Empire.

Turkish horse archers, of whom the Seljuqs were rep-resentative, were lightly armoured and mounted but ex-tremely mobile. Their armour generally consisted of an iron helmet and, perhaps, a shirt of mail or scale armour (called brigandine). They carried small, light, one-handed shields, usually of wicker fitted with an iron boss. Their principal offensive arms were lance, sabre, and bow. The Turkish bow developed in response to the demands of mounted combat against lightly armoured adversaries on the open steppe; as a consequence, it seems to have had greater range but less penetrative and knockdown power at medium and short ranges than its Byzantine equivalents. Turkish horses, though hardy and agile, were not as large or powerful as Byzantine chargers. Therefore, Turkish horse archers could not stand up to a charge of Byzantine cataphracts, but their greater mobility generally enabled them to stay out of reach and fire arrows from a distance, wearing their adversaries down and killing their horses.

The Mongols. The 13th-century Mongol armies of Genghis Khan and his immediate successors depended on large herds of grass-fed Mongolian ponies, as many as six or eight to a warrior. The ponies were relatively small but agile and hardy, well-adapted to the harsh climate of the steppes. The Mongol warrior's principal weapon was the composite recurved bow, of which he might carry as many as three. Characteristically, each man carried a short bow for use from the saddle and a long bow for use on foot. The former, firing light arrows, was for skirmishing

and long-range harassing fire; the latter had the advantage in killing power at medium ranges. The saddle bow was probably capable of sending a light arrow more than 500 yards; the heart of the long bow's engagement envelope would have been about 100–350 yards, close to that of the contemporary English longbow. Each warrior carried several extra quivers of arrows on campaign. He also carried a sabre or scimitar, a lasso, and perhaps a lance. Personal armour included a helmet and breastplate of iron or lacquered leather, though some troops wore shirts of scale or mail.

Mongol armies were proficient at military engineering and made extensive use of Chinese technology, including catapults and incendiary devices. These latter probably included predecessors of gunpowder, of which the Mon-gols were the likely vehicle of introduction into western Europe.

The infantry revolution, c. 1200–1500

The appearance of the crossbow as a serious military implement along the northern rim of the western Mediter-ranean at about the middle of the 9th century marked a growing divergence between the technology of war in Europe and that of the rest of the world. It was the first of a series of technological and tactical developments that culminated in the rise of infantry elites to a position of tactical dominance. This infantry revolution began when the crossbow spread northward into areas that were periph-eral to the economic, cultural, and political core of feudal Europe and where the topography was unfavourable for mounted shock action and the land too poor to support an armoured elite. Within this closed military topography, the crossbow soon proved itself the missile weapon par excellence of positional and guerrilla warfare.

The reasons for the crossbow's success were simple: crossbows were capable of killing the most powerful of mounted warriors, yet they were far cheaper than war-horses and armour and were much easier to master than the skills of equestrian combat. Also, it was far easier to learn to fire a crossbow than a long bow of equiva-lent power. Serious war bows had significant advantages over the crossbow in range, accuracy, and maximum rate of fire, but crossbowmen could be recruited and trained quickly as adults, while a lifetime of constant practice was required to master the Turkish or Mongol composite bow or the English longbow.

The crossbow directly challenged the mounted elite's dominance of the means of armed violence—a point that the lay and ecclesiastical authorities did not miss. In 1139 the second Lateran Council banned the crossbow under penalty of anathema as a weapon "hateful to God and unfit for Christians," and Emperor Conrad III of Ger-many (reigned 1138–52) forbade its use in his realms. But the crossbow proved useful in the Crusades against the infidel and, once introduced, could not be eradicated in any event. This produced a grudging acceptance among the European mounted elites, and the crossbow under-went a continuous process of technical development to-ward greater power that ended only in the 16th century, with the replacement of the crossbow by the harquebus and musket.

An independent, reinforcing, and almost simultaneous development was the appearance of the English longbow as the premier missile weapon of western Europe. The sig-nal victory of an outnumbered English army of longbow-men and dismounted men-at-arms over mounted French chivalry supported by mercenary Genoese crossbowmen at Crécy on Aug. 26, 1346, marked the end of massed cavalry charges by European knights for a century and a half (see Figure 6).

Another important and enduring discovery was made by the Swiss. At the Battle of Morgarten in 1315, Swiss *eid-genossen,* or "oath brothers," learned that an unarmoured man with a seven-foot (200-centimetre) halberd could dispatch an armoured man-at-arms. Displaying striking adaptability, they replaced some of their halberds with the pike, an 18-foot spear with a small, piercing head. No longer outreached by the knight's lance, and displaying

Figure 6: *Crossbow and longbow at the Battle of Crécy, 1346.*
Although the crossbow was deadly at short range, the longbow's greater range and
faster rate of fire enabled English longbowmen (right) to sweep the field at Crécy of Italian
crossbowmen and French horsemen (left). Both weapons signaled the end of medieval
chivalry. From the *Chronicles* of Jean Froissart, 14th century. In the Bibliothèque Nationale,
Paris (MS. Français 2643, fol. 165v).
Bibliothèque Nationale, Paris

far greater cohesion than any knightly army, the Swiss soon showed that they could defeat armoured men-at-arms, mounted or dismounted, given anything like even numbers. With the creation of the pike square tactical formation, the Swiss provided the model for the modern infantry regiment.

THE CROSSBOW

The idea of mounting a bow permanently at right angles across a stock that was fitted with a trough for the arrow, or bolt, and a mechanical trigger to hold the drawn string and release it at will was very old. Crossbows were buried in Chinese graves in the 5th century BC, and the crossbow was a major factor in Chinese warfare by the 2nd century BC at the latest. The Greeks used the crossbow principle in the *gastrophetes,* and the Romans knew the crossbow proper as the *manuballista,* though they did not use it extensively. The European crossbow of the Middle Ages differed from all of these in its combination of power and portability.

In Europe, crossbows were progressively developed to penetrate armour of increasing thicknesses. In China, on the other hand, crossbow development emphasized rapidity of fire rather than power; by the 16th century, Chinese artisans were making sophisticated lever-actuated rapid-fire crossbows that carried up to 10 bolts in a self-contained magazine. These, however, were feeble weapons by contemporary European standards and had relatively little penetrating power.

Mechanical cocking aids freed the crossbow from the limitations of simple muscular strength. If the bow could be held in a drawn state by a mechanical trigger, then the bow could be drawn in progressive stages using levers, cranks, and gears or windlass-and-pulley mechanisms, thereby multiplying the user's strength. The power of such a weapon, unlike that of the bow, was thus not limited by the constraints of a single muscular spasm.

The crossbowman, unlike the archer, did not have to be particularly strong or vigorous, and his volume of fire was not as limited by fatigue. Nevertheless, the crossbow had serious tactical deficiencies. First, ordinary crossbows for field operations (as opposed to heavy siege crossbows)

Tactical deficiencies of the crossbow

were outranged by the bow. This was because crossbow bolts were short and heavy, with a flat base to absorb the initial impact of the string. The flat base and relatively crude leather fins (crossbow bolts were produced in volume and were not as carefully finished as arrows) were aerodynamically inefficient, so that velocity fell off more quickly than that of an arrow. These factors, combined with the inherent lack of precision in the trigger and release mechanism, made the ordinary military crossbow considerably shorter-ranged and less accurate than a serious military bow in the hands of a skilled archer. Also, the advantage of the crossbow's greater power was offset by its elaborate winding mechanisms, which took more time to use. The combination of short range, inaccuracy, and slow rate of fire meant that crossbowmen in the open field were extremely vulnerable to cavalry.

The earliest crossbows had a simple bow of wood alone. However, such bows were not powerful enough for serious military use, and by the 11th century they gave way to composite bows of wood, horn, and sinew. The strength of crossbows increased as knightly armour became more effective, and, by the 13th century, bows were being made of mild steel. (The temper and composition of steel used for crossbows had to be precisely controlled, and the expression "crossbow steel" became an accepted term designating steel of the highest quality.) Because composite and steel crossbows were too powerful to be cocked by the strength of the arms alone, a number of mechanical cocking aids were developed. The first such aid of military significance was a hook suspended from the belt: the crossbowman could step down into a stirrup set in the front of the bow's stock, loop the bowstring over the hook, and by straightening up use the powerful muscles of his back and leg to cock the weapon. The belt hook was inadequate for cocking the steel crossbows required to penetrate plate armour, and by the 14th century military crossbows were being fitted with removable windlasses and rack-and-pinion winding mechanisms called cranequins. Though slow, these devices effectively freed the crossbow from limitations on its strength: draw forces well in excess of 1,000 pounds became common, particularly for large siege crossbows.

THE ENGLISH LONGBOW

The longbow evolved during the 12th century in response to the demands of siege and guerrilla operations in the Welsh Marches, a topographically close and economically marginal area that was in many ways similar to the regions in which the crossbow had evolved three centuries earlier. It became the most effective individual missile weapon of western Europe until well into the age of gunpowder and was the only foot bow since classical times to equal the composite recurved bow in tactical effectiveness and power.

While it was heavily dependent on the strength and competence of its user, the longbow in capable hands was far superior to the ordinary military crossbow in range, rate of fire, and accuracy. Made from a carefully cut and shaped stave of yew or elm, it varied in length, according to the height of the user, from about five to seven feet. The longbow had a shorter maximum range than the short, stiff composite Turkish or Mongol saddle bows of equivalent draw force, but it could drive a heavy arrow through armour with equal efficiency at medium ranges of 150–300 yards. Each archer would have carried a few selected light arrows for shooting at extreme ranges and could probably have reached 500 yards with these.

Training the longbow-man

The longbow's weakness was that of every serious military bow: the immense amounts of time and energy needed to master it. Confirmation of the extreme demands placed on the archer was found in the skeletal remains of a bowman who went down with the English ship *Mary Rose*, sunk in Portsmouth Harbour in 1545. The archer (identified as such by a quiver, its leather strap still circling his spine) exhibited skeletal deformations caused by the stresses of archery: the bones of his left forearm showed compression thickening, his upper backbone was twisted radially, and the tips of the first three fingers of his right hand were markedly thickened, plainly the results of a lifetime of drawing a bow of great strength. The longbow was dependent upon the life-style of the English yeomanry, and, as that life-style changed to make archery less remunerative and time for its practice less available, the quality of English archery declined. By the last quarter of the 16th century there were few longbowmen available, and the skill and strength of those who responded to muster was on the whole well below the standards of two centuries earlier. An extended debate in the 1580s between advocates of the longbow and proponents of gunpowder weapons hinged mainly on the small numbers and limited skills of available archers, not around any inherent technical deficiency in the weapon itself.

HALBERD AND PIKE

The halberd.   The halberd was the only significant medieval shock weapon without classical antecedents. In its basic form, it consisted of a six-foot shaft of ash or another hardwood, mounted by an ax blade that had a forward point for thrusting and a thin projection on the back for piercing armour or pulling a horseman off balance. The halberd was a specialized weapon for fighting armoured men-at-arms and penetrating knightly armour. With the point of this weapon, a halberdier could fend off a mounted lancer's thrusts and, swinging the cutting edge with the full power of his arms and body, could cleave armour, flesh, and bone. The halberd's power was counterbalanced by the vulnerability of taking a full swing with both arms; once committed, the halberdier was totally dependent upon his comrades for protection. This gave halberd fighting a ferocious all-or-nothing quality and placed a premium on cohesion (see Figure 7).

Pikeman versus cavalry-man

The pike.   While the halberd could penetrate the best plate armour, allowing infantrymen to inflict heavy casualties on their mounted opponents, the lance's advantage in length meant that men-at-arms could inflict heavy casualties in return. The solution was the pike, a staff, usually of ash, that was twice the length of the halberd and had a small piercing head about 10 inches (25 centimetres) long. Sound infantry armed with the pike could fend off cavalry with ease, even when outnumbered. As with the halberd, effectiveness of shock action with the pike was heavily dependent upon the cohesion and solidity of

Figure 7: *Halberd and pike in battle near Ins, Berne canton, in 1375.*

the troops wielding it. The pike remained a major factor in European warfare until, late in the 17th century, the bayonet gave missile-armed infantry the ability to repel charging cavalry.

The gunpowder revolution, c. 1300–1650

Few inventions have had an impact on human affairs as dramatic and decisive as that of gunpowder. The development of a means of harnessing the energy released by a chemical reaction in order to drive a projectile against a target marked a watershed in the harnessing of energy to human needs. Before gunpowder, weapons were designed around the limits of their users' muscular strength; after gunpowder, they were designed more in response to tactical demand.

Technologically, gunpowder bridged the gap between the medieval and modern eras. By the end of the 19th century, when black powder was supplanted by nitrocellulose-based propellants, steam power had become a mature technology, the scientific revolution was in full swing, and the age of electronics and the internal combustion engine was at hand. The connection between gunpowder and steam power is instructive. Steam power as a practical reality depended on the ability to machine iron cylinders precisely and repetitively to predetermined internal dimensions; the methods for doing this were derived from cannon-boring techniques.

Gunpowder bridged the gap between the old and the new intellectually as well as technologically. Black powder was a product of the alchemist's art, and although alchemy presaged science in believing that physical reality was determined by an unvarying set of natural laws, the alchemist's experimental method was hardly scientific. Gunpowder was a simple mixture combined according to empirical recipes developed without benefit of theoretical knowledge of the underlying processes. The development of gunpowder weapons, however, was the first significant success in rationally and systematically exploiting an energy source whose power could not be perceived directly with the ordinary senses. As such, early gunpowder technology was an important precursor of modern science.

EARLY GUNPOWDER

Chinese alchemists discovered the recipe for what became known as black powder in the 9th century AD; this was a mixture of finely ground potassium nitrate (also called saltpetre), charcoal, and sulfur in approximate proportions of 75:15:10 by weight. The resultant gray powder behaved differently from anything previously known; it exploded

Chinese origin of black powder

on contact with open flame or a red-hot wire, producing a bright flash, a loud report, dense white smoke, and a sulfurous smell. It also produced considerable quantities of superheated gas, which, if confined in a partially enclosed container, could drive a projectile out of the open end. The Chinese used the substance in rockets, in pyrotechnic projectors much like Roman candles, in crude cannon, and, according to some sources, in bombs thrown by mechanical artillery. This transpired long before gunpowder was known in the West, but development in China stagnated. The development of black powder as a tactically significant weapon was left to the Europeans, who probably acquired it from the Mongols in the 13th century (though diffusion through the Arab Muslim world is also a possibility).

Chemistry and internal ballistics. Black powder differed from modern propellants and explosives in a number of important particulars. First, only some 44 percent by weight of a properly burned charge of black powder was converted into propellant gases, the balance being solid residues. The high molecular weights of these residues limited the muzzle velocities of black-powder ordnance to about 2,000 feet (600 metres) per second. Second, unlike modern nitrocellulose-based propellants, the burning rate of black powder did not vary significantly with pressure or temperature. This occurred because the reaction in an exploding charge of black powder was transmitted from grain to grain at a rate some 150 times greater than the rate at which the individual grains were consumed and because black powder burned in a complex series of parallel and mutually dependent exothermal (heat-producing) and endothermal (heat-absorbing) reactions that balanced each other out. The result was an essentially constant burning rate that differed only with the grain size of the powder; the larger the grains, the less surface area exposed to combustion and the slower the rate at which propellant gases were produced.

Nineteenth-century experiments revealed sharp differences in the amount of gas produced by charcoal burned from different kinds of wood. For example, dogwood charcoal decomposed with potassium nitrate was found to yield nearly 25 percent more gas per unit weight than fir, chestnut, or hazel charcoal and some 17 percent

more than willow charcoal. These scientific observations confirmed the insistence of early—and thoroughly unscientific—texts that charcoal from different kinds of wood was suited to different applications. Willow charcoal, for example, was preferred for cannon powder and dogwood charcoal for small arms—a preference substantiated by 19th-century tests. (A preference for urine instead of water as the incorporation agent might have had some basis in fact because urine is rich in nitrates; so might the view that a beer drinker's urine was preferable to that of an abstemious person and a wine drinker's urine best of all.) For all this, the empirically derived recipe for gunpowder was fixed during the 14th century and hardly varied thereafter. Subsequent improvements were almost entirely concerned with the manufacturing process and with the ability to purify and control the quality of the ingredients.

Serpentine powder. The earliest gunpowder was made by grinding the ingredients separately and mixing them together dry. This was known as serpentine. The behaviour of serpentine was highly variable, depending on a number of factors that were difficult to predict and control. If packed too tightly and not confined, a charge of serpentine might fizzle; conversely, it might develop internal cracks and detonate. When subjected to vibration, as when being transported by wagon, the components of serpentine separated into layers according to relative density, the sulfur settling to the bottom and the charcoal rising to the top. Remixing at the battery was necessary to maintain the proper proportions—an inconvenient and hazardous procedure producing clouds of noxious and potentially explosive dust.

Corned powder. Shortly after 1400, smiths learned to combine the ingredients of gunpowder in water and grind them together as a slurry. This was a significant improvement in several respects. Wet incorporation was more complete and uniform than dry mixing, the process

"froze" the components permanently into a stable grain matrix so that separation was no longer a problem, and wet slurry could be ground in large quantities by waterdriven mills with little danger of explosion. The use of waterpower also sharply reduced cost.

After grinding, the slurry was dried in a sheet or cake. It was then processed in stamping mills, which typically used hydraulically tripped wooden hammers to break the sheet into grains. After being tumbled to wear the sharp edges off the grains and impart a glaze to their surface, they were sieved. The grain size varied from coarse—about the size of grains of wheat or corn (hence the name corned powder)—to extremely fine. Powder too fine to be used was reincorporated into the slurry for reprocessing. Corned powder burned more uniformly and rapidly than serpentine; the result was a stronger powder that rendered many older guns dangerous.

Refinements in ballistics. Late medieval and early modern gunners preferred large-grained powder for cannon, medium-grained powder for shoulder arms, and fine-grained powder for pistols and priming—and they were correct in their preferences. In cannon the slower burning rate of large-grained powder allowed a relatively massive, slowly accelerating projectile to begin moving as the pressure built gradually, reducing peak pressure and putting less stress on the gun. The fast burning rate of fine-grained powders, on the other hand, permitted internal pressure to peak before the light, rapidly accelerating projectile of a small arm had exited the muzzle. But the early modern gunner had no provable rationale for his preferences, and in the 18th century European armies standardized on finegrained musket powder for cannon as well as small arms.

Then, beginning in the late 18th century, the application of science to ballistics began to produce practical results. The ballistic pendulum, invented by the English mathematician Benjamin Robins, provided a means of measuring muzzle velocity and, hence, of accurately gauging the effective power of a given quantity of powder. A projectile was fired horizontally into the pendulum's bob (block of wood), which absorbed the projectile's momentum and converted it into upward movement. Momentum is the product of mass and velocity, and the law of conservation of momentum dictates that the total momentum of a system is conserved, or remains constant. Thus the projectile's velocity, v, may be determined from the equation $mv = (m + M)V$, which gives

$$v = \frac{m + M}{m} V,$$

where m is the mass of the projectile, M is the mass of the bob, and V is the velocity of the bob and embedded projectile after impact.

The initial impact of science on internal ballistics was to show that traditional powder charges for cannon were much larger than necessary. Refinements in the manufacture of gunpowder followed. About 1800 the British introduced cylinder-burned charcoal—that is, charcoal burned in enclosed vessels rather than in pits. With this method, wood was converted to charcoal at a uniform and precisely controlled temperature. The result was greater uniformity and, since fewer of the volatile trace elements were burned off, more powerful powder. Later, powder for very large ordnance was made from charcoal that was deliberately "overburned" to reduce the initial burning rate and, hence, the stress on the gun.

Beginning in the mid-19th century, the use of extremely large guns for naval warfare and coastal defense pressed existing materials and methods of cannon construction to the limit. This led to the development of methods for measuring pressures within the gun, which involved cylindrical punches mounted in holes drilled at right angles through the barrel. The pressure of the propellant gases forced the punches outward against soft copper plates, and the maximum pressure was then determined by calculating the amount of pressure needed to create an indentation of equal depth in the copper. The ability to measure pressures within a gun led to the design of cannon made thickest where internal pressures were greatest—that is, near the breech. The resultant "soda bottle" cannon of the mid- to

late 19th century, which had fat breeches curving down to short, slim muzzles, bore a strange resemblance to the very earliest European gun of which a depiction survives, that of the Walter de Millimete manuscript of 1327.

THE DEVELOPMENT OF ARTILLERY

The de Millimete gun

The earliest known gunpowder weapons vaguely resembled an old-fashioned soda bottle or a deep-throated mortar and pestle. The earliest such weapon, depicted in the English de Millimete manuscript, was some three feet long with a bore diameter of about two inches (five centimetres). The projectile resembled an arrow with a wrapping around the shaft, probably of leather, to provide a gas seal within the bore. Firing was apparently accomplished by applying a red-hot wire to a touchhole drilled through the top of the thickest part of the breech. The gun was laid horizontally on a trestle table without provision for adjusting elevation or absorbing recoil—a tribute to its modest power, which would have been only marginally greater than that of a large crossbow.

The breakthrough that led to the emergence of true cannon derived from three basic perceptions. The first was that gunpowder's propellant force could be used most effectively by confining it within a tubular barrel. This stemmed from an awareness that gunpowder's explosive energy did not act instantaneously upon the projectile but had to develop its force across time and space. The second perception was that methods of construction derived from cooperage could be used to construct tubular wrought-iron gun barrels. The third perception was that a spherical ball was the optimal projectile. The result was modern artillery.

Wrought-iron muzzle-loaders. The earliest guns were probably cast from brass or bronze. Bell-founding techniques would have sufficed to produce the desired shapes, but alloys of copper, tin, and zinc were expensive and, at first, not well adapted to the containment of high-temperature, high-velocity gases. Wrought iron solved both of these problems. Construction involved forming a number of longitudinal staves into a tube by beating them around a form called a mandrel and welding them together. (Alternatively, a single sheet of iron could be wrapped around the mandrel and then welded closed; this was particularly suitable for smaller pieces.) The tube was then reinforced with a number of rings or sleeves (in effect, hoops). These were forged with an inside diameter about the same as the outside of the tube, raised to red or white heat, and slid into place over the cooled tube, where they were held firmly in place by thermal contraction. The sleeves or rings were butted against one another and the gaps between them sealed by a second layer of hoops. Forging a strong, gastight breech presented a particular problem that was usually solved by welding a tapered breech plug between the staves.

Hoop-and-stave construction permitted the fabrication of guns far larger than had been made previously. By the last quarter of the 14th century, wrought-iron siege bombards were firing stone cannonballs of 450 pounds (200 kilograms) and more. These weapons were feasible only with projectiles of stone. Cast iron has about two and a half times the density of marble or granite, and gunners quickly learned that a cast-iron cannonball with a charge of good corned powder behind it was unsafe in any gun large enough for serious siege work.

Wrought-iron breechloaders. Partly because of the difficulties of making a long, continuous barrel, and partly because of the relative ease of loading a powder charge into a short breechblock, gunsmiths soon learned to make cannon in which the barrel and powder chamber were separate. Since the charge and projectile were loaded into the rear of the barrel, these were called breechloaders. The breechblock was mated to the barrel by means of a recessed lip at the chamber mouth. Before firing, it was dropped into the stock and forced forward against the barrel by hammering a wedge into place behind it; after the weapon was fired, the wedge was knocked out and the block was removed for reloading. This scheme had significant advantages, particularly in the smaller classes of naval swivel guns and fortress wallpieces, where the use of multiple breechblocks permitted a high rate of fire. Small breechloaders continued to be used in these ways well into the 17th century.

Problems with early breechloading

The essential deficiency of early breechloaders was the imperfect gas seal between breechblock and barrel, a problem that was not solved until the advent of the brass cartridge late in the 19th century. Hand-forging techniques could not produce a truly gastight seal, and combustion gases escaping through the inevitable crevices eroded the metal, causing safety problems. Wrought-iron cannon must have required constant maintenance and care, particularly in a saltwater environment.

Wrought-iron breechloaders were the first cannon to be produced in significant numbers. Their tactical viability was closely linked to the economics of cannonballs of cut stone, which, modern preconceptions to the contrary, were superior to cast-iron projectiles in many respects. Muzzle velocities of black-powder weapons were low, and smoothbore cannon were inherently inaccurate, so that denser projectiles of iron had no advantage in effective range. Cannon designed to fire a stone projectile were considerably lighter than those designed to fire an iron ball of the same weight; as a result, stone-throwing cannon were for many years cheaper. Also, because stone cannonballs were larger than iron ones of the same weight, they left larger holes after penetrating the target. The principal deficiency of stone-throwing cannon was the enormous amount of skilled labour required to cut a sphere of stone accurately to a predetermined diameter. The acceleration of the wage–price spiral in the 15th and 16th centuries made stone-throwing cannon obsolete in Europe.

Cast bronze muzzle-loaders. The advantages of cast bronze for constructing large and irregularly shaped objects of a single piece were well understood from sculpture and bell founding, but a number of problems had to be overcome before the material's plasticity could be applied to ordnance. Most important, alloys had to be developed that were strong enough to withstand the shock and internal pressures of firing without being too brittle. This was not simply a matter of finding the optimal proportions of copper and tin; bronze alloys used in cannon founding were prone to internal cavities and "sponginess," and foundry practices had to be developed to overcome the inherent deficiencies of the metal. The essential technical problems were solved by the first decades of the 15th century, and, by the 1420s and '30s, European cannon founders were casting bronze pieces that rivaled the largest of the wrought-iron bombards in size.

The importance of the trunnion

Developments in foundry practice were accompanied by improvements in weapon design. Most notable was the practice of casting cylindrical mounting lugs, called trunnions, integral with the barrel. Set just forward of the centre of gravity, trunnions provided the principal point for attaching the barrel to the carriage and a pivot for adjusting the vertical angle of the gun. This permitted the barrel to be adjusted in elevation by sliding a wedge, or quoin, beneath the breech. At first, trunnions were supplemented by lifting lugs cast atop the barrel at the centre of gravity; by the 16th century most European founders were casting these lugs in the shape of leaping dolphins, and a similarly shaped fixture was often cast on the breech of the gun.

Toward the end of the 15th century, French founders combined these features with efficient gun carriages for land use. French carriage design involved suspending the barrel from its trunnions between a pair of heavy wooden side pieces; an axle and two large wheels were then mounted forward of the trunnions, and the rear of the side pieces descended to the ground to serve as a trail. The trail was left on the ground during firing and absorbed the recoil of the gun, partly through sliding friction and partly by digging into the ground. Most important, the gun could be transported without dismounting the barrel by lifting the trail onto the limber, a two-wheeled mount that served as a pivoting front axle and point of attachment for the team of horses. This improved carriage, though heavy in its proportions, would have been familiar to a gunner of Napoleonic times. Sometime before the middle of the 16th century, English smiths developed a highly compact four-wheeled truck carriage for mounting trunnion-equipped

Figure 8: *Cast-bronze cannon of Maximilian I of Bavaria.*
Designed to smash fortress walls with a solid shot of iron, these large artillery pieces were lifted onto their wooden carriages by handles cast into the top of the barrel. Each carriage was carved from a single timber. From *Geschützbuch oder Zeugbuchs Kaiser Maximilian,* about 1500. In the Bayerische Staatsbibliothek, Munich (Cod. icon. 222, fol. 45v).
Bayerische Staatsbibliothek, Munich

shipboard ordnance, resulting in cannon that would have been familiar to a naval gunner of Horatio Nelson's day.

By the early 1500s, cannon founders throughout Europe had learned to manufacture good ordnance of cast bronze (see Figure 8). Cannon were cast in molds of vitrified clay, suspended vertically in a pit. Normally, they were cast breech down; this placed the molten metal at the breech under pressure, resulting in a denser and stronger alloy around the chamber, the most critical point. Subsequent changes in foundry practice were incremental and took effect gradually. As founders established mastery over bronze, cannon became shorter and lighter. In about 1750, advances in boring machines and cutting tools made it possible for advanced foundries to cast barrels as solid blanks and then bore them out. Until then cannon were cast hollow—that is, the bore was cast around a core suspended in the mold. Ensuring that the bore was precisely centred was a particularly critical part of the casting process, and small wrought-iron fixtures called chaplets were used to hold the core precisely in place. These were cast into the bronze and remained a part of the gun. Boring produced more accurate weapons and improved the quality of the bronze, since impurities in the molten metal, which gravitate toward the centre of the mold during solidification, were removed by the boring. But, while these changes were important operationally, they represented only marginal improvements to the same basic technology. A first-class bronze cannon of 1500 differed hardly at all in essential technology and ballistic performance from a cannon of 1850 designed to shoot a ball of the same weight. The modern gun would have been shorter and lighter, and it would have been mounted on a more efficient carriage, but it would have fired its ball no farther and no more accurately.

Cast-iron cannon. In 1543 an English parson, working on a royal commission from Henry VIII, perfected a method for casting reasonably safe, operationally efficient cannon of iron. The nature of the breakthrough in production technology is unclear, but it probably involved larger furnaces and a more efficient organization of resources. Cast-iron cannon were significantly heavier

Enduring value of cast-bronze cannon

and bulkier than bronze guns firing the same weight of ball. Unlike bronze cannon, they were prone to internal corrosion. Moreover, when they failed, they did not tear and rupture like bronze guns but burst into fragments like a bomb. They possessed, however, the overwhelming advantage of costing only about one-third as much. This gave the English, who alone mastered the process until well into the 17th century, a significant commercial advantage by enabling them to arm large numbers of ships. The Mediterranean nations were unable to cast significant quantities of iron artillery until well into the 19th century.

Terminology and classification. Early gunpowder artillery was known by a bewildering variety of names. (The word cannon became dominant only gradually, and the modern use of the term to describe a gun large enough to fire an explosive shell did not emerge until the 20th century.) The earliest efficient wrought-iron cannon were called bombards or lombards, a term that continued in use well into the 16th century. The term basilisk, the name of a mythical dragonlike beast of withering gaze and flaming breath, was applied to early "long" cannon capable of firing cast-iron projectiles, but, early cannon terminology being anything but consistent, any particularly large and powerful cannon might be called a basilisk.

Founders had early adopted the practice of classifying cannon by the weight of the ball, so that, for example, a 12-pounder fired a 12-pound cannonball. By the 16th century, gunners had adopted the custom of describing the length of a cannon's bore in calibres, that is, in multiples of the bore diameter. These became basic tools of classification and remained so into the modern era with certain categories of ordnance such as large naval guns. Also by the 16th century, European usage had divided ordnance into three categories according to bore length and the type of projectile fired. The first category was the culverins, "long" guns with bores on the order of 30 calibres or more. The second was the cannons, or cannon-of-battery, named for their primary function of battering down fortress walls; these typically had barrels of 20 to 25 calibres. The third category of ordnance was the pedreros, stone-throwing guns with barrels of as little as eight to 10 calibres that were used in siege and naval warfare.

Mortars were a separate class of ordnance. With very wide bores of even fewer calibres than those of the pedreros, they were used in siege warfare for lobbing balls at a very high trajectory (over 45°). Mortars owed their name to the powder chamber of reduced diameter that was recessed into the breech; this made them similar in appearance to the mortars used to pulverize grain and chemicals by hand. Unlike the longer cannon, mortars were cast with trunnions at the breech and were elevated by placing wedges beneath the muzzle.

Special-purpose shot. Both culverins and cannon-of-battery generally fired cast-iron balls. When fired against masonry walls, heavy iron balls tended to pulverize stone and brick. Large stone cannonballs, on the other hand, were valued for the shock of their impact, which could bring down large pieces of wall. Undercutting the bottom of a wall with iron cannonballs, then using the heavy impact of large stone shot to bring it down, was a standard tactic of siege warfare. (Ottoman gunners were particularly noted for this approach.)

In the 15th century exploding shot was developed by filling hollow cast-iron balls with gunpowder and fitting a fuze that had to be lit just before firing. These ancestors of the modern exploding shell were extremely dangerous to handle, as they were known to explode prematurely or, with equally catastrophic results, jam in the gun barrel. For this reason they were used only in the short-bored mortars.

Exploding shot

For incendiary purposes, iron balls were heated red-hot in a fire before loading. (In that case, moist clay was sometimes packed atop the wadding that separated the ball from the powder charge.) Other projectiles developed for special purposes included the carcass, canister, grapeshot, chain shot, and bar shot. The carcass was a thin-walled shell containing incendiary materials. Rounds of canister and grapeshot consisted of numerous small missiles, usually iron or lead balls, held together in various ways for

simultaneous loading into the gun but designed to separate upon leaving the muzzle. Because they dispersed widely upon leaving the gun, the projectiles were especially effective at short range against massed troops. Bar shot and chain shot consisted of two heavy projectiles joined by a bar or a chain. Whirling in their trajectories, they were especially effective at sea in cutting the spars and rigging of sailing vessels.

Gunnery. During most of the black-powder era, with smoothbore cannon firing spherical projectiles, artillery fire was never precisely accurate at long ranges. (Aiming and firing were particularly difficult in naval gunnery, since the gunner had to predict the roll of the ship in order to hit the target.) Gunners aimed by sighting along the top of the barrel, or "by the line of metals," then stepped away before firing to avoid the recoil. The basic relationship between range and elevation being understood, some accuracy was introduced through the use of the gunner's quadrant, in which the angle of elevation of a gun barrel was measured by inserting one leg of the quadrant into the barrel and reading the angle marked on the scale by a vertically hanging plumb line. Nevertheless, the inherent inaccuracy of smoothbore artillery meant that most shooting was done at short ranges of 1,000 yards or less; at these ranges, estimating elevation by rule of thumb was sufficient. For attacking fortress walls, early modern gunners preferred a range of 60 to 80 yards; a range of 100 to 150 yards was acceptable, but 300 yards or more was considered excessive.

THE FIRST SMALL ARMS

Small arms did not exist as a distinct class of gunpowder weapon until the middle of the 15th century. Until then, hand cannon differed from their larger relatives only in size. They looked much the same, consisting of a barrel fastened to a simple wooden stock that was braced beneath the gunner's arm. A second person was required to fire the weapon. About the middle of the 15th century, a series of connected developments established small arms as an important and distinct category of weaponry. The first of these was the development of slow match—or match, as it was commonly called. This was cord or twine soaked in a solution of potassium nitrate and dried. When lit, match smoldered at the end in a slow, controlled manner. Slow match found immediate acceptance among artillerists and remained a standard part of the gunner's kit for the next four centuries.

The matchlock. Small arms appeared during the period 1460–80 with the development of mechanisms that applied match to hand-portable firearms. German gunsmiths apparently led the way. The first step was a simple S-shaped "trigger," called a serpentine, fastened to the side of a hand cannon's stock. The serpentine was pivoted in the middle and had a set of adjustable jaws, or dogs, on the upper end that held the smoldering end of a length of match. Pulling up on the bottom of the serpentine brought the tip of the match down into contact with powder in the flashpan, a small, saucer-shaped depression surrounding the touchhole atop the barrel. This arrangement made it possible for one gunner to aim and fire, and it was quickly improved on. The first and most basic change was the migration of the touchhole to the right side of the barrel, where it was served by a flashpan equipped with a hinged or pivoting cover that protected the priming powder from wind, rain, and rough handling. The serpentine was replaced by a mechanism, enclosed within the gunstock, that consisted of a trigger, an arm holding the match with its adjustable jaws at the end, a sear connecting trigger and arm, and a mechanical linkage opening the flashpan cover as the match descended. These constituted the matchlock, and they made possible modern small arms.

One final refinement was a spring that drove the arm holding the match downward into the pan when released by the sear. This mechanism, called the snap matchlock, was the forerunner of the flintlock. The fabrication of these devices fell to locksmiths, the only sizable body of craftsmen accustomed to constructing metal mechanisms with the necessary ruggedness and precision. They gave to the firing mechanism the enduring name lock.

The first mechanical firing device

The development of mechanical locks was accompanied by the evolution of gunstocks with proper grips and an enlarged butt to transmit the recoil to the user's body. The result was the matchlock harquebus, the dominant military small arm of the 15th century and the direct ancestor of the modern musket. The harquebus was at first butted to the breastbone, but, as the power of firearms increased, the advantages of absorbing the recoil on the shoulder came to be appreciated. The matchlock harquebus changed very little in its essentials until it was replaced by the flintlock musket in the final years of the 17th century.

The wheel lock. The principal difficulty with the matchlock mechanism was the need to keep a length of match constantly smoldering. German gunsmiths addressed themselves to this problem early in the 16th century. The result was the wheel lock mechanism, consisting of a serrated wheel rotated by a spring and a spring-loaded set of jaws that held a piece of iron pyrites against the wheel. Pulling the trigger caused the wheel to rotate, directing a shower of sparks into the flashpan. The wheel lock firearm could be carried in a holster and kept ready to fire indefinitely, but, being delicate and expensive, it did not spread beyond cavalry elites and had a limited impact on warfare as a whole.

The flintlock. Flintlock firing mechanisms were known by the middle of the 16th century, about a hundred years before they made their appearance in quantity in infantry muskets. A flintlock was similar to a wheel lock except that ignition came from a blow of flint against steel, with the sparks directed into the priming powder in the pan. This lock was an adaptation of the tinderbox used for starting fires.

In the several different types of flintlocks that were produced, the flint was always held in a small vise, called a cock, which described an arc around its pivot to strike the steel (generally called the frizzen) a glancing blow. A spring inside the lock was connected through a tumbler to the cock. The sear, a small piece of metal attached to the trigger, either engaged the tumbler inside the lock or protruded through the lock plate to make direct contact with the cock (see Figure 9).

Flintlocks were not as surefire as either the matchlock or the wheel lock, but they were cheaper than the latter,

Tactical
value of
flint and
steel

contained fewer delicate parts, and were not as difficult to repair in primitive surroundings. In common with the wheel locks they had the priceless advantage of being ready to fire immediately. A flintlock small arm was slightly faster to load than a matchlock, if the flint itself did not require adjustment.

FORTIFICATION

Before gunpowder artillery, a well-maintained stone castle, secured against escalade by high curtain walls and flanking towers, provided almost unbreachable security against attack. Artillery at first did little to change this. Large wrought-iron cannon capable of throwing wall-smashing balls of cut stone appeared toward the end of the 14th century, but they were neither efficient nor mobile. Indeed, the size and unwieldiness of early firearms and cannon suited them more for fortress arsenals than for the field, and adjustments to gunpowder by fortification engineers quickly tilted the balance of siege operations toward the defense. Gunports were cut low in walls for covering ditches with raking fire, reinforced platforms and towers were built to withstand the recoil shock of defensive cannon, and the special firing embrasures for crossbows were modified into gunports for hand cannon, with sophisticated vents to carry away the smoke. The name of the first truly effective small arm, the *hackenbüsche,* or hackbutt, is indicative: the weapon took its name, literally "hook gun," from a projection welded beneath the forward barrel that was hooked over the edge of a parapet in order to absorb the piece's recoil.

From medieval to modern.   The inviolability of the medieval curtain wall came to an end in the 15th century, with the development of effective cast-bronze siege cannon. Many of the basic technical developments that led to the perfection of heavy bronze ordnance were pioneered by German founders. Frederick I, elector of Brandenburg from 1417 to 1425, used cannon systematically to defeat the castles of his rivals one by one in perhaps the earliest politically decisive application of gunpowder technology. The French and Ottomans were the first to bring siege artillery to bear in a decisive manner outside their own immediate regions. Charles VII of France (reigned 1422–61) used siege artillery to reduce English forts in the last stages of the Hundred Years' War. When his grandson Charles VIII invaded Italy in 1494, the impact of technically superior French artillery was immediate and dramatic; the French breached in eight hours the key frontier fortress of Monte San Giovanni, which had previously withstood a siege of seven years.

The impact of Ottoman siege artillery was equally dramatic. Sultan Mehmed II breached the walls of Constantinople in 1453 by means of large bombards, bringing the Byzantine Empire to an end and laying the foundations of Ottoman power. The Turks retained their superiority in siegecraft for another generation, leveling the major Venetian fortifications in southern Greece in 1499–1500 and marching unhindered through the Balkans before being repulsed before Vienna in 1529.

The shock of the sudden vulnerability of medieval curtain walls to French, Ottoman, and, to a lesser extent, German siege cannon quickly gave way to attempts by military engineers to redress the balance. At first, these consisted of the obvious and expensive expedients of counter-battery fire. By the 1470s, towers were being cut down to the height of the adjacent wall, and firing platforms of packed earth were built behind walls and in the lower stories of towers. Italian fortress architects experimented with specially designed artillery towers with low-set gunports sited to sweep the fortress ditch with fire; some were even sited to cover adjacent sections of wall with flanking fire. However, most of these fortresses still had high, vertical walls and were therefore vulnerable to battery.

A definitive break with the medieval past was marked by two Italian sieges. The first of these was the defense of Pisa in 1500 against a combined Florentine and French army. Finding their wall crumbling to French cannon fire, the Pisans in desperation constructed an earthen rampart behind the threatened sector. To their surprise and relief, they discovered not only that the sloping earthen rampart

The fall
of stone
curtain
walls

could be defended against escalade but that it was far more resistant to cannon shot than the vertical stone wall that it supplanted. The second siege was that of Padua in 1509. Entrusted with the defense of this Venetian city, a monk-engineer named Fra Giocondo cut down the city's medieval wall. He then surrounded the city with a broad ditch that could be swept by flanking fire from gunports set low in projections extending into the ditch. Finding that their cannon fire made little impression on these low ramparts, the French and allied besiegers made several bloody and fruitless assaults and then withdrew.

The **sunken profile.**   While Pisa demonstrated the strength of earthen ramparts, Padua showed the power of a sunken profile supported by flanking fire in the ditch. With these two cities pointing the way, basic changes were undertaken in fortress design. Fortress walls, still essential for protection against escalade, were dropped into the ground behind a ditch and protected from battery by gradually sloping earthen ramparts beyond. A further refinement was the sloping of the glacis, or forward face of the ramparts, in such a manner that it could be swept by cannon and harquebus fire from the parapet behind the ditch. As a practical matter the scarp, or main fortress wall, now protected from artillery fire by the glacis, was faced with brick or stone for ease of maintenance; the facing wall on the forward side of the ditch, called the counterscarp, was similarly faced. Next, a level, sunken space behind the glacis, the covered way, was provided so that defenders could assemble for a sortie under cover and out of sight of the attackers. This, and the provision of firing embrasures for cannon in the parapet wall, completed the basics of the new fortress profile (see Figure 10).

Protecting
the wall
from
cannon fire

Refinements of the basic sunken design included a palisade of sharpened wooden stakes either in the ditch or immediately behind the glacis and a sunken, level path behind the parapet for ammunition carts, artillery reinforcements, and relief troops. As attacking and defending batteries became larger, fortress designers placed greater emphasis on outworks intended to push the besieging batteries farther back and out of range.
Figure 10: *Profile of the European fortress wall from the 16th century.*
The fortress wall, called the scarp, was sunk into the ground behind a ditch. A sloping earthen rampart, called the glacis, deflected cannonballs and gave defenders a free field of fire.

The profile of the outworks was designed according to the same basic principles applied to the fortress. Well established by 1520, these principles remained essentially unchanged until rifled artillery transformed positional warfare in the mid-19th century.

The **bastioned trace.**   The sunken profile was only half the story of early modern fortress design; the other half was the trace, the outline of the fortress as viewed from above. The new science of trace design was based, in its early stages, on the bastion, a projection from the main fortress wall from which defending fire could sweep the face of adjacent bastions and the wall between. Actually, bastions had been introduced before engineers were fully aware of the power of artillery, so that some early 16th-century Italian fortifications combined sophisticated bastioned traces with outmoded high walls, a shallow ditch, and little or no protective glacis. After early experimentation with rounded contours, which were believed to be stronger, designers came to appreciate the advantages of bastions with polygonal shapes, which eliminated the dead space at the foot of circular towers and provided

uninterrupted fields of view and fire. Another benefit of the polygonal bastion's long, straight sections of wall was that larger defensive batteries could be mounted along the parapets.

The relatively simple traces of the early Italian bastioned fortresses proved vulnerable to the ever larger armies and ever more powerful siege trains of the 16th century. In response, outworks were developed, such as ravelins (detached outworks in front of the bastions) and demilunes (semidetached outworks in the ditch between bastions), to shield the main fortress walls from direct battery. The increasing scale of warfare and the greater resources available to the besieger accelerated this development, and systems of outworks grew more and more elaborate and sprawling as a means of slowing the attacker's progress and making it more costly.

By the late 17th century, fortress profiles and traces were closely integrated with one another and with the ground on which they stood. The sophistication of their designs is frequently linked with the name of the French military engineer Sébastien Le Prestre de Vauban.

Duration of early modern fortification. With various refinements, the early modern fortress, based on a combination of the sunken profile and bastioned trace, remained the basic form of permanent fortification until the American Civil War, which saw the first extensive use of heavy rifled cannon made of high-quality cast iron. These guns not only had several times the effective range and accuracy of their predecessors, but they were also capable of firing explosive shells. They did to the early modern fortress what cast-bronze cannon had done to the medieval curtain wall. In 1862 the reduction by rifled Union artillery of Fort Pulaski, a supposedly impregnable Confederate fortification defending Savannah, Ga., marked the beginning of a new chapter in the design of permanent fortifications. MODERN WEAPONS AND WEAPON SYSTEMS

Small arms

Since the introduction of the flintlock musket in the 17th century, military small arms have gone through a series of significant changes. By employing different projectiles and successively improved chemical propellants, the dual goal of most arms designers has been the creation of man-portable weapons of greater firepower and reduced weight. But the attainment of this goal has continually been hampered by an inescapable physical relationship between the recoil forces generated by gunpowder weapons and the mass and velocity of their projectiles. In order to reduce the weight of a weapon, its recoil energy has to be reduced, but reducing recoil also affects the killing power of the bullet. Given the constraints of this relationship, military small arms may well have reached a level where, within reasonable economic limits, significantly higher performance cannot be obtained merely by improving existing gunpowder-based technology.

SHOULDER WEAPONS

Muzzle-loaders. Practical shoulder-fired small arms started with the perfection of the flintlock ignition system in the mid-17th century (see above *Military technology before the modern era: The gunpowder revolution, c. 1300–1650*). Earlier gunpowder small arms, based on the matchlock or wheel lock mechanisms, were generally too heavy, too unreliable, or too expensive to allow for general

issue to infantry forces. Indeed, the first matchlock *mosquetes* ("muskets") fielded by Spanish infantry weighed as much as 25 pounds (10 kilograms) and usually required a forked staff as a rest to enable a man of normal strength to fire them accurately from the shoulder. Nevertheless, they were capable of sending bullets through the best armour that could be worn by a mobile soldier. Almost overnight, firepower from muskets became the dominant force in war, and fully armoured soldiers almost disappeared from European battlefields toward the end of the 16th century. With armour-piercing power no longer necessary, muskets could be made smaller, and shoulder weapons without rests became the norm.

The introduction of new ignition systems did not immediately render older forms obsolete, however; all systems, in many variations, existed side by side. Wheel locks and matchlocks, for example, persisted into the 18th century, long after flintlocks had established their primacy in Europe and America.

Standardized patterns and parts. Flintlock small arms emerged at the start of industrialization, with weapons production becoming one of the first industrial sectors to exploit the transition from craft production to the large-scale production of the Industrial Revolution. On the military side, these weapons entered service at a time when the scale of ground forces employed in battle was increasing. The ability to manufacture large numbers of muskets enabled military leaders to equip these mass armies.

By the 1600s European military authorities had begun moving toward greater uniformity in order to eliminate mixed inventories of nonstandard weapons. England took the first steps toward creating a national system of small-arms manufacture. For years, completed muskets had been purchased from a variety of English, Irish, and Dutch gunmakers, who subcontracted for components and arranged for final assembly. Beginning in the early 1700s, ordnance officials, from their headquarters at the Tower of London, divided the manufacture of firearms into locks, stocks, barrels, ramrods, and furniture—all of which they sought to purchase directly from subcontractors. Since different components for the same weapon were made in different locations, Tower officials oversaw the establishment of "Sealed Patterns" (sample firearms) to serve as exact models for gunmakers.

An Ordnance Office decree of 1722 led to a standard army musket, called the "Long Land," which had a 46-inch (1,168-millimetre) barrel and a calibre, or bore diameter, of .75 inch (19 millimetres). The Long Land became popularly known in America as the first model Brown Bess musket. Fighting experience in the wilderness of North America during the Seven Years' War, or French and Indian War (1756–63), suggested the utility of lighter and shorter muskets, and in 1768 the Short Land musket, with a 42-inch barrel, became standard. Known as the second model Brown Bess, the Short Land became one of the basic weapons used in the American Revolution (1775–83). It was succeeded in 1797 by the "India Pattern," with a 39-inch barrel. During the wars with Napoleon from 1804 to 1815, more than 1.6 million of these muskets were assembled in Birmingham, and nearly 2.7 million muskets of all types were "fitted up" in London and at the Lewisham Royal Armoury Mills. In 1816 assembly work was divided between London and a new Royal Small Arms Factory at Enfield Lock, Middlesex.

In France, standard-pattern muskets did not exist prior to 1717, when the government specified a weapon with a 47-inch barrel and a calibre of .69 inch. (This calibre remained standard until the 19th century.) After the Seven Years' War, the French army introduced the Modèle 1763, with a stronger lock and shorter (45-inch) barrel—a length that remained standard to century's end. The Modèle 1777 musket represented a major step forward because of improved production techniques, with the French creating a rigorous system of patterns and gauges that yielded muskets with nearly interchangeable parts. This process was intended to produce less expensive muskets that were easier to make and repair, but worker resistance delayed large-scale manufacture of small arms using interchangeable parts until the early 1800s. Had the program succeeded earlier, France would have been better equipped to fight the Napoleonic Wars. As it was, French firms in such provincial cities as Charleville, Maubeuge, Saint-Étienne, and Tulle fabricated fewer than two million small arms.

The U.S. government created national armouries at Springfield, Mass., and at Harpers Ferry, Va., in 1794; work at Springfield commenced in 1795, and arms production began at Harpers Ferry in 1801. Both built an Americanized version of the French Modèle 1777 musket (known as the Model 1795 in the United States). These armouries and their private competitors later became important centres of technological innovation. With the adoption of the .69-inch Model 1842, the U.S. military introduced the large-scale assembly of weapons from uniform, interchangeable parts. By the mid-1850s arms makers around the world were beginning to copy this "American System" of manufacture, which contributed to the creation of the modern military small arm—especially after the introduction of percussion ignition and rifled barrels.

Percussion ignition. The Model 1842 was based on the Model 1840 flintlock, but it featured a switch to percussion ignition. This newer system was based on the explosive property of potassium chlorate and fulminate of mercury, both of which detonate when struck a small, sharp blow by a striker. Several Germans experimented with detonating fulminates in the late 17th century, and the French did likewise in the 18th century, but it was Alexander John Forsyth, a Scottish clergyman, who successfully wedded priming powders to the ignition of firearms in 1805, receiving a patent in April 1807. Forsyth invented the "scent bottle" type of lock mechanism, so called because rotating on a tapered steel plug at about the location of a flintlock touchhole was a powder-filled container that looked like a perfume bottle. Turning the bottle upside down released some detonator powder into a cavity at the top of the plug, and turning the bottle back left the striker mechanism, consisting of a hammer rather than the cock and jaws of the flintlock, free to operate. When the trigger was pulled, the hammer fell, detonating the compound.

Subsequent inventors simplified the percussion lock mechanism by using loose or pellet detonating powder. By 1830, percussion caps (attributed to the Philadelphian Joshua Shaw in 1815) were becoming the accepted system for igniting firearm powder charges. A percussion cap was a truncated cone of metal (preferably copper) that contained a small amount of fulminate of mercury inside its crown, protected by foil and shellac. This cap was fitted onto a steel nipple mounted at the weapon's breech, and a small channel in the nipple communicated the flash from the cap to the powder chamber. In the final form of this mechanism, a hollow-nosed percussion hammer came down over the percussion cap, thus eliminating the danger of flying copper when the powder detonated. Percussion cap ignition was easily adapted to existing flintlock muskets and pistols.

Rifling. As killing machines, smoothbore infantry muskets were relatively inefficient. Their heavy, round lead balls delivered bone-crushing and tissue-destroying blows when they hit a human body, but beyond 75 yards even trained infantrymen found it difficult to hit an individual adversary. Volley fire against massed troops delivered effective projectiles out to 200 yards, but at 300 yards balls from muzzle-loaders lost most of their lethality. Also, while well-trained soldiers could load and shoot their muskets five times per minute, volley fire led to a collective rate of only two to three shots per minute.

Short-comings of smooth-bore muskets

These ballistic shortcomings were a product of the requirement that the projectile, in order to be quickly rammed from muzzle to breech, had to fit loosely in the barrel. When discharged, it wobbled down the barrel, contributing to erratic flight after it left the muzzle. Rifled barrels, in which spiral grooves were cut into the bore, were known to improve accuracy by imparting a gyroscopic spin to the projectile, but reloading rifled weapons was slowed because the lead ball had to be driven into the barrel's rifling. Greased cloth or leather patches eased the problem somewhat, but the rate of fire of rifles was still much lower than that of smoothbore muskets.

One possible solution was the creation of mechanisms that allowed the bullet to be loaded at the breech instead of the muzzle. Many such ideas were tested during the 18th century, but, given the craftsman-based manufacture

of the day, none was suited to large-scale production. Special army units in Europe and America used rifled muzzle-loaders, such as the flintlock British Baker rifle, to harass the enemy at long ranges, while most infantrymen continued to carry muzzle-loading smoothbores. For this reason, inventors concentrated on adapting rifled barrels to muzzle-loaders. In 1826 Henri-Gustave Delvigne of France, seeking a means of expanding the projectile without making it difficult to ram home, created a narrow powder chamber at the breech end of the barrel against which a loosely fitting lead ball came to rest. Ramrod blows expanded the soft lead at the mouth of the chamber so that, when fired, the bullet fit the rifling tightly. In 1844 another French officer, Louis-Étienne de Thouvenin, introduced yet a better method for expanding bullets. His *carabine à tige* embodied a post or pillar (*tige*) at the breech against which the bullet was expanded.

These rifles worked better than earlier types, but their deformed balls flew with reduced accuracy. Captain Claude-Étienne Minié, inspired by Delvigne's later work with cylindrical bullets, designed longer, smaller-diameter projectiles, which, having the same weight as larger round balls, possessed greater cross-sectional density and therefore retained their velocity better. Moreover, while the flat base of Minié's projectile was deformed against the pillar as in Thouvenin's weapon, the rest of the bullet maintained its shape and accuracy. The French army combined these ideas in the Carabine Modèle 1846 à tige and the Fusil d'Infanterie Modèle 1848 à tige.

In order to combat the tendency of muzzle-loading rifles to become difficult to load as gunpowder residue collected in the barrels, Minié suggested a major simplification—eliminating the pillar and employing in its place a hollow-based bullet with an iron expander plug that caused the projectile to engage the rifling when the weapon was fired. This new projectile could be loaded into dirty rifles with ease, and, because it was not deformed while loading, it had greater accuracy.

Officials in several countries, notably Britain and the United States, saw the significance of Minié's invention. In 1851 the Royal Small Arms Factory, Enfield, embarked upon production of the .702-inch Pattern 1851 Minié rifle (see Figure 11). In the Crimean War (1854–56), Russian troops armed with smoothbore muskets were no match for Britons shooting P/51 rifles. Massed formations were easy prey, as were cavalry and artillery units. A correspondent for the *Times* of London wrote: "The Minié is king of weapons . . . the volleys of the Minié cleft [Russian soldiers] like the hand of the Destroying Angel."

The Enfield Pattern 1851

Swiss experiments demonstrated that an expander plug was not necessary when a bullet's side walls were thin enough, and the British designed a smaller-calibre rifle using this type of Minié bullet. The result was a .577-inch weapon firing "cylindro-conoidal" projectiles—essentially a lead cylinder with a conical nose. "Enfield" as a weapon name was first generally applied to these Pattern 1853 rifles. Subsequent tests indicated that rifles with 33-inch barrels could provide accuracy equal to the 39-inch P/53 barrels. When the resulting P/53 Short Rifles were issued, there began a century-long trend toward shorter weapons.

In the United States, experiments undertaken in the late 1840s led to the adoption of a .58-inch Minié-type bullet and a family of arms designed to use it. The Model 1855 rifled musket, with a 40-inch barrel, produced a muzzle velocity of 950 feet (290 metres) per second. All Model 1855 weapons used mechanically operated tape priming, intended to eliminate the manual placement of percussion caps on the nipple, but this system proved too fragile and was eliminated with the introduction of a simplified Model 1861 rifled musket. During the American Civil War (1861–65), the Union government purchased both Model 1861 and Model 1863 rifled muskets as its basic infantry weapon. In the Confederacy, domestic production was supplemented by purchases of Enfield P/53 rifles and other European weapons.

The Civil War clearly demonstrated the deadly effect of rifled muskets, although many battlefield commanders only slowly appreciated the changing nature of warfare. Individual soldiers could hit their opposing numbers with

accurate fire out to 250 yards, so that frontal assaults, in which soldiers advanced in neat ranks across open fields, had to be abandoned. By 1862 both sides were building field entrenchments and barricades to provide protection from rifle and artillery fire.

Breechloaders. *The bolt action.* The American Civil War also previewed the importance of breech-loading rifles. For more than a century, soldiers carrying muzzle-loaders had been issued paper cartridges containing the musket ball and an appropriate powder charge. To use one of these cartridges, they simply bit off the end of the paper tube, poured a little powder into the pan (if the gun was a flintlock), dumped the rest down the barrel, and then rammed the ball and paper down on top. Some early breechloaders used slightly improved cartridges of nitrate-soaked paper or linen that contained the powder and ball and were inserted into the opened breech as a unit. The powder was set off when sparks from the flashpan ignited either the flammable case itself or exposed powder at the end of the cartridge. Other breechloaders employed metal cartridges that were pierced with holes or made with ends of flammable paper, so that the powder could be ignited by a percussion cap. But all of these systems, which relied upon externally mounted flintlock or percussion ignition mechanisms, were prone to misfiring, and they did little to prevent the leakage of gas and flame for which breechloaders were notorious. Breech-loading rifles became practical only with the design of cartridges that housed the primer as well as the propellant in a single case, and that provided an effective seal when the weapon was fired.

The first such cartridge to be successfully employed in war was of the rimfire type, in which a ring of detonating fulminate was deposited in a hollow rim around the base of a thin copper case. An external hammer crushed the rim in one spot, firing the round. Unfortunately, some fulminate compounds detonated unpredictably, leading to both misfires and premature explosions. Also, a cartridge case that was soft enough to be crushed by a striker could not stand up to the heavy propellant charge necessary for a full-power infantry rifle. For this reason, rimfire cartridges were used most effectively in pistols or—during the American Civil War—in smaller repeating carbines such as the .56-inch Spencer and the .44-inch Henry.

In Europe, a milestone in the development of breech-loading infantry weapons was achieved by Johann Nikolaus Dreyse, a Prussian. His *Zündnadelgewehr* ("needle-fired gun"), introduced in 1838, used a paper cartridge with a priming pellet located at the base of a solid egg-shaped bullet. A long, needle-shaped firing pin, shot forward by a spring, pierced the cartridge and powder charge to detonate the primer. This needle was housed in a steel cylinder called the bolt, which slid forward in the frame of the receiver until it was locked firmly against the base of the cartridge in the chamber. Once the weapon was fired, the soldier released a latch with his thumb, grasped a knob at the end of a handle projecting from the bolt, turned it until locking lugs on the bolt were disengaged from slots in the receiver, and slid the bolt back to open the chamber for reloading. This bolt action, simple in concept and yet requiring precise workmanship, constituted a revolution in small-arms design.

The first Dreyse rifles were adopted by the Prussian army in 1843 and were used in campaigns in 1849 and 1864. In 1866, notably at the Battle of Königgrätz during the Seven Weeks' War, Prussian soldiers lying prone were able to fire six shots from their 15.43-millimetre (.607-inch) Zündnadelgewehr Modell 1862 for every one discharged from their Austrian opponents' muzzle-loading rifles.

Prussia's success encouraged other European states to adopt bolt-action breechloaders. The French employed Antoine-Alphonse Chassepot's 11-millimetre Fusil d'Infanterie Modèle 1866 to devastating effect in such battles of the Franco-German War (1870–71) as Mars-la-Tour and Gravelotte. Close-order troop formations disappeared from the European scene as a result of these fights, and the cavalry charge was relegated to the past. The Chassepot rifle employed a shorter firing pin than the Dreyse, because its cartridge was fitted with a detonating cap at the very base. About 1.03 million of these weapons were in hand when the war began, and Prussia had some 1.15 million Dreyse needle rifles—a quantity that demonstrated the value of machine production of weapons with interchangeable parts.

Needle rifles offered a faster rate of fire, but their paper cartridges provided a poor seal at the breech, and their long firing pins warped or broke under heavy use. One solution was the metallic centre-fire cartridge with a percussion cap centred in the base of a hard brass or copper case. A shorter, sturdier firing pin was sufficient to detonate the primer, and a metallic case that was strong enough to withstand a powerful propellant charge also provided effective closure of the breech. Adopting centre-fire cartridges, France transformed its Chassepots into the 11-millimetre Modèle 1866/67 and 1874 rifles, which were named after their designer, Basile Gras. Germany went to rifles designed by Peter Paul Mauser, first the 11-millimetre Modell 1871 Gewehr and then the Modell 1871/84 Infanterie-Repetier-Gewehr. The latter was a 10-shot repeater that ejected the spent case as the bolt was pulled back and fed a fresh cartridge into the chamber from a tubular magazine beneath the barrel as the bolt was pushed forward.

All other European countries soon adopted cartridge breech-loading rifles, usually by converting existing muzzle-loaders and then by purchasing purpose-built breechloaders. Many did not feature bolt action. For example, beginning in 1866, Britain converted its P/53 Enfields simply by hinging the top of the breech so that it could be opened sideways, the spent case extracted, and a fresh cartridge inserted. In 1871 the British went to new Martini-Henry breechloaders of .45-inch calibre. In these rifles, pushing down a lever attached to the trigger guard lowered the entire breechblock, exposing the chamber, and raised the breechblock back to firing position when it was pulled back. Russia adopted two new 10-millimetre breechloaders, the Model 1868 Berdan No. 1 and then the bolt-action Model 1870 Berdan No. 2, both of which were largely the work of American Civil War officer Hiram Berdan. The U.S.-made Remington Rolling Block Rifle, in which the breechblock was cocked back on a hinge like the hammer, was bought by a number of countries around the world. The United States itself adopted a series of single-shot rifles employing a hinged-breech "trap-door" mechanism, developed by Erskine S. Allin at the Springfield Armory, in which the top of the breech was flipped forward along the top of the barrel. The first Model 1866 was a converted .58-inch musket, the second Model 1866 was a new rifle in .50-inch calibre, and subsequent versions were built in .45-inch calibre. These weapons, born of postwar starvation budgets, continued to use components introduced with the Model 1855 muzzle-loaders.

The smokeless-powder revolution. All early breechloaders used black powder as their source of propellant energy, but in the early 1880s more powerful and cleaner-burning nitrocellulose-based propellants were perfected. Whereas black powder produced a large quantity of solid material upon combustion, quickly fouling barrels and pouring out huge clouds of smoke, nitrocellulose produced mostly gas and was therefore labeled "smokeless powder." Also, it produced three times the energy of black powder and burned at a more controllable rate. Such characteristics made possible a shift to longer and smaller-diameter projectiles. Bore diameters were again reduced, this time to calibres of about .30 inch, or 7.5 to 8 millimetres. Muzzle velocities ranged from 2,000 to 2,800 feet per second, and accurate range extended to 1,000 yards and beyond. Because lead projectiles were too soft to be used at such increased power and velocity, they were sheathed in harder metal. In 1881 a Swiss officer, Eduard Alexander Rubin, was the first to perfect a full-length, copper-jacketed bullet.

Magazine repeaters. France was the first country to issue a small-bore, high-velocity repeating rifle, the Modèle 1886 Lebel, which fired an 8-millimetre, smokeless-powder round. The tubular magazine of this rifle soon became obsolete, however. In 1885 Ferdinand Mannlicher of Austria had introduced a boxlike magazine fitted into the bottom of the rifle in front of the trigger guard. This magazine was easily loaded by a device called a clip, a

light metal openwork box that held five cartridges and fed them up into the chamber through the action of a spring as each spent case was ejected. Other magazine rifles, such as the Mauser, used a different loading device, called a charger. This was simply a flat strip of metal with its edges curled to hook over the rims or grooves of a row of cartridges (also usually five). To load his rifle, a soldier drew back the bolt, slipped the charger into position above the opened receiver, and pushed the cartridges down into the magazine, where they were held in tension against a spring. The efficiency of the box magazine was quickly recognized, as was its special compatibility with the bolt action, and all European states made the conversion. For example, Germany adopted the 8-millimetre Model 1888 Commission rifle, Belgium the 7.65-millimetre Model 1889 Mauser, Turkey the Model 1890 Mauser, and Russia the 7.62-millimetre Model 1891 Mosin-Nagant. In 1892 Britain abandoned movable-block action and went to the .303-inch, bolt-action Lee-Metford, and the United States began to purchase the .30-inch Model 1892 Krag-Jørgensen, a Danish design. In 1906 Japan adopted the 6.5-millimetre Year 38 Arisaka rifle.

By World War I (1914–18) all major powers adopted smokeless-powder, bolt-action, magazine-fed repeating rifles, and some had shifted to a second generation. Austria, for example, issued the Modell 1895 Mannlicher, firing an 8-millimetre round, and German troops carried the 7.92-millimetre Modell 1898, designed by Mauser (see Figure 11). For durability, safety, and efficiency, the 1898 Mauser was probably the epitome of bolt-action military rifles. It was sold and copied around the world. In the United States the Mauser was only slightly altered and issued as the .30-inch M1903 Springfield.

Also following Germany's lead in the design of ammunition, all armies replaced their blunt-nosed projectiles with aerodynamically superior pointed bullets (in German, *Spitzgeschossen*). Barrel lengths continued to decrease, partly in response to more efficient propellants and partly to make rifles easier to use in the field. The British .303-inch Short, Magazine, Lee-Enfield rifle, known as the SMLE, had a 25-inch barrel, while the M1903 Springfield's barrel measured just over 23.75 inches.

During the Great War, huge quantities of rifles were built. British factories made more than 3.9 million rifles, German sources produced about 5 million, and Russian factories built more than 9 million. Still, most armies suffered from shortages. Factories in the United States made 1.24 million rifles for the British and 280,000 for the Russians; for U.S. forces they produced 2.4 million between May 1917 and December 1918 alone.

Automatic weapons. *The self-loading rifle.* Magazine-fed rifles provided a radical increase in rate of fire. Indeed, by 1914 many British riflemen could fire 15 aimed shots per minute, and some very skillful individuals could exceed 30 shots per minute. Nevertheless, in order to transcend the limits imposed by manual operation, gun designers such as Mannlicher and the American Hiram Maxim came up with experimental self-loading, or semi-

automatic, rifles, which used the energy generated by a fired round to load a fresh round into the chamber. However, only a handful of these weapons were adopted in very small numbers by the major armies, whose interest in automatic fire from the 1880s through World War I was directed primarily toward heavier infantry-support weapons (see below *Machine guns*).

After the war, all nations having an arms industry sought to produce a semiautomatic rifle, but only the United States was successful in developing and manufacturing a battle-worthy weapon. Adopted in 1936, the U.S. Rifle, Caliber .30 M1, designed by John C. Garand, was a technological tour de force (see Figure 12). A small hole or gas port on the underside of its barrel near the muzzle directed part of the propellant gases into a small cylinder holding a piston that was connected to the bolt. As gas pressure forced back the piston and bolt, the empty cartridge case was ejected and the hammer was cocked. A spring then forced the bolt forward. As it moved forward, the bolt stripped the top cartridge from an eight-round, clip-loaded magazine within the receiver and seated it in the chamber, ready to fire. Gas pressure thus performed automatically the reloading task formerly done by hand.

As the only semiautomatic rifle to become a standard-issue infantry weapon, the M1 was extremely durable and reliable in combat. Between 1937 and 1945, the Springfield Armory and the Winchester Repeating Arms Company produced 4.04 million of these rifles. Still, infantry units of most other belligerents during World War II (1939–45) were armed with bolt-action rifles of the World War I era as their standard weapons.

The submachine gun. The ballistic performance of infantry rifles was tailored to the long-range requirements of a bygone era when foot soldiers demanded weapons that could reach out to halt the dreaded cavalry charge. Beginning early in World War I, however, battlefields became no-man's-lands pockmarked by shell craters and crisscrossed by miles of barbed-wire entanglements, and machine guns dominated the 1,000 or more yards between trench lines. While rifles were shot at those extreme ranges, they could not equal the destructive power of artillery and machine guns, and they were too cumbersome and powerful for offensive assaults on enemy trenches. A generation later, in World War II, the greater mobility of troops accompanying armoured vehicles reinforced the need for lighter, more portable weapons of improved effectiveness at close quarters.

Such changing conditions led to experiments with automatic weapons firing rounds of lower velocity or lighter weight. One result, which saw its first use in World War I, was a new weapon called the machine carbine or submachine gun. Derived from the semiautomatic pistol and firing pistol-calibre ammunition with muzzle velocities of only about 1,000 feet per second, submachine guns were fitted with shoulder stocks (and sometimes forward hand grips). Such weapons offered easier handling than rifles while providing greater accuracy and more rapid fire than most handguns.

The first successful weapon of this type was the Maschinen Pistole 1918 Bergmann, designed by Hugo Schmeisser and employed by the Germans during the last few months of the war. The barrel of the MP18 was less than eight inches long, and it was chambered for nine-millimetre rounds introduced in 1908 for Parabellum, or Luger, pistols. It operated under a principle called blowback, in which the spent cartridge case, blown backward out of the chamber by the gases generated by the firing of the round, forced the bolt back against a spring and tripped the mechanism that ejected the case from the gun. The spring then forced the bolt forward as a fresh cartridge was fed into the chamber. If the trigger was kept depressed, the new round would be fired automatically, and the cycle would continue until the trigger was released or the ammunition was exhausted. In blowback actions, the bolt had to be quite heavy, or it had to be subjected to various devices that retarded its backward motion, in order to keep the mechanism from operating faster than was desired. In the MP18, a heavy bolt and spring limited the weapon's rate of fire to about 400 rounds per minute.

After the war, Vasily Degtyarev of the Soviet Union incorporated Schmeisser's principles into his own designs, culminating in the Pistolet Pulemyot Degtyarova of 1940. The PPD was fed by a drum-shaped magazine containing 71 7.62-millimetre cartridges, and it fired at a rate of 900 rounds per minute—far too fast for accuracy. In the United States, John T. Thompson's submachine gun, chambered for the .45-inch Colt pistol cartridge, was adopted by the army in 1928. Popularly called the "tommy gun," the M1928 was effective, but its blowback operation was modified by a complex retarding mechanism that was deleted from later versions, when its large drum magazine was also replaced by a box magazine.

Under the pressures of World War II, the major powers used millions of submachine guns. These included a second generation of simplified weapons that, being fabricated partly from sheet-metal stampings, could be produced in quantity almost anywhere and at little expense. The Germans led the way with the MP38 and MP40. Known to the Allies as "burp guns," these weapons operated at 450 to 550 rounds per minute, the optimal rate for controlled fire. Also, they were fed by a box magazine, which did not jam as often as a drum, and had a wire shoulder stock that could be folded against the receiver. Meanwhile, the Soviets issued en masse the PPSh of 1941 and the PPS of 1943. The latter closely resembled the new German guns, as did the United States' M3, called the "grease gun" for its resemblance to a mechanic's grease dispenser. The British Sten gun, extremely simple and inexpensive yet very effective, was issued to paratroops and commandos beginning in 1941 and was also smuggled to partisans in Europe.

After the war, almost all new submachine guns, such as the British Sterling and West German MP5, were chambered for nine-millimetre cartridges. As a class of weapon, they received a new lease on life with the telescoping bolt, pioneered by Václav Holek in the Czechoslovak Model 23 of 1948. This involved a hollowed-out bolt that slid partially over the barrel when a round was chambered, resulting in a much shorter weapon. A prominent example of this type was the Israeli Uzi, designed by Uziel Gal, which was only 25 inches long with its shoulder stock extended. The Uzi was adopted around the world as a police and counterterrorist weapon. Indeed, aside from arming special forces, the submachine gun lost importance as a military weapon. With an effective range limited to about 200 yards, it could not fill the broad gap between the low-power pistol cartridge and the full-power rifle cartridge. This gap, which constituted the ground upon which modern infantrymen found themselves fighting, had to be filled by another new weapon, which would fire a cartridge of intermediate power.

The assault rifle. A hint at this new weapon had been given during World War I, when Vladimir Grigorevich Fyodorov, father of Russian automatic weapons, married the 6.5-millimetre cartridge of the Japanese Arisaka rifle to an automatic rifle. In 1916 he unveiled his new weapon, the Avtomat Fyodorova. Owing to the turmoil of the Russian Revolution of 1917, only about 3,200 of Fyodorov's weapons were delivered. Nevertheless, they pointed the way to future infantry weapon design.

During World War II, Hugo Schmeisser designed a light rifle to fire the Germans' 7.92-millimetre Kurz, or "Short," cartridge, which was of the same calibre as the Mauser rifle cartridge but was lighter and shorter and was therefore of a less potent, "intermediate" power. The weapon, known variously as the MP43, MP44, or Sturmgewehr ("Assault Rifle") 44, was loaded by a curved box magazine holding 30 rounds and was designed for most effective fire at about 300 yards. Only 425,000 to 440,000 of these rifles were built—too few and too late for the German war effort—but they were based on a concept that would dominate infantry weapons for the rest of the century.

Late in the war the Soviets also began a search for a rifle to shoot their 7.62-millimetre intermediate cartridge, which produced a muzzle velocity of 2,330 feet per second. Historical evidence suggests that they were influenced by the Sturmgewehr, but to what extent remains uncertain. In 1947 they adopted a weapon designed by Mikhail Timofeyevich Kalashnikov, naming it the Avtomat Kalashnikova. Like the German weapon, the AK-47 (see Figure 12) was operated by diverting some of the propellant gases into a cylinder above the barrel; this drove a piston that forced the bolt back against its spring and cocked the hammer for the next round. At the turn of a selector switch, the action could be changed from semiautomatic to fully automatic, firing at a rate of 600 rounds per minute. The AK-47 was made of forged and milled steel, giving it a weight of 10.6 pounds (4.8 kilograms) with a loaded 30-round magazine.

Sheet-
metal
fabrication

The AK-47

The receiver of the AKM version, introduced in 1959, was made of lighter sheet metal, reducing the weight to 8.3 pounds, and the AK-74 version, following later trends in the West, switched to a 5.45-millimetre cartridge.

Kalashnikov's assault rifles became the most significant infantry weapons of the post-World War II era. In many variants, they were adopted and made by countries all over the world. Between 30 and 50 million AKs were produced within four decades of the series' introduction, more than any other firearm in history.

The development of Western small arms proceeded more slowly, mainly because the United States insisted upon maintaining a power level comparable to the M1. As a result, in 1953 the North Atlantic Treaty Organization (NATO) reluctantly agreed to standardize on a 7.62-millimetre cartridge that was a half-inch shorter than the M1 cartridge but of the same calibre and power. To fire this new round, the United States produced an improved version of the M1 rifle, featuring a 20-round detachable magazine and being capable of selective fire. Called the U.S. Rifle 7.62mm M14, it replaced the M1, beginning in 1957. As a self-loading rifle the M14 performed well, but it was too heavy as a close-quarters weapon, and the extreme recoil generated by the NATO round caused it to be totally unmanageable as an automatic rifle.

Other NATO armies adopted more satisfactory 7.62-millimetre rifles, although even these were employed as advanced self-loaders rather than automatics. Most commonly, they were either the gas-operated Fusil Automatique Léger (FAL), introduced by the Belgian Fabrique Nationale d'Armes de Guerre in 1957, or the blowback-operated Gewehr 3 (G3), produced in West Germany by the firm Heckler & Koch, beginning in 1959. Millions of these weapons were sold to many countries.

After the Korean War (1950–53), U.S. military researchers dissatisfied with rifle-power ammunition began to test a .22-inch (5.56-millimetre) cartridge that propelled a lighter projectile at a much higher muzzle velocity of 3,000 feet per second. To fire this "small-calibre, high-velocity" round, in 1958 they chose the AR-15 rifle, designed by Eugene M. Stoner for the ArmaLite Division of Fairchild Engine and Airplane Corporation. The AR-15 was gas-operated, but it eliminated the piston in favour of a tube that directed propellant gases directly into an expansion chamber between the bolt and bolt carrier. By reducing the number of working parts and chambering the rifle for a smaller cartridge, Stoner had come up with a lightweight weapon that, even on automatic fire, produced a manageable recoil and yet was capable of inflicting fatal wounds at 300 yards and beyond. In 1961 the air force purchased the AR-15, renaming it the M16. Six years later, with units in Vietnam finding the weapon very effective under the close conditions of jungle warfare, the army adopted it as the M16A1.

After U.S. troops in Europe were issued the M16, a series of trials ensued that ended with the decision, in 1980, to adopt a standard 5.56-millimetre NATO cartridge. This fired a brass-jacketed projectile that, having a heavier lead core and steel nose, was lethal at longer ranges than the original AR-15 bullet. The M16A2 was rifled to fire this round, and other NATO armies switched over. West Germany introduced the G41, a 5.56-millimetre version of the G3, and Belgium replaced the FAL with the FNC. The British and French armies developed new assault rifles with compact "bullpup" designs, in which the bolt, receiver, and magazine were behind the handgrip and trigger and much of the shoulder stock was occupied by the operating mechanism. This permitted a much shorter weapon than orthodox designs, in which the magazine and receiver were ahead of the trigger. As a result, the French FA MAS and British L85A1 were only some 30 to 31 inches long—compared with the M16, which was 39 inches overall. Many of the newer models were built with lightweight plastic shoulder stocks and magazines, as well as receivers made of aluminum.   (E.C.E.)

The AR-15/ M16

MACHINE GUNS

The search for greater firepower has not been limited to shoulder firearms. In addition to personal-defense weapons,

a variety of infantry-support weapons classed as machine guns have been subjected to intense experimentation.

Early manual weapons.   During the flintlock era a number of heavy guns were developed that could fire several bullets either serially or in volley, but it was not until the mid-19th century, with the spread of centre-fire cartridge ammunition and better manufacturing techniques, that such weapons could be put to effective military use. The best known were the Gatling gun, invented by the American Richard J. Gatling, and the mitrailleuse, produced by the Belgian firm of Christophe & Montigny.

The Gatling gun.   Gatling guns had several barrels (usually 6 or 10) mounted around a central axle and revolved by means of a hand crank. After a barrel fired a round, it went through successive unlocking, extracting, ejecting, reloading, and relocking. In the most successful Gatling guns, stacks of rounds could be fed by means of a feed device to give continuous fire for long periods. Gatling weapons were made to take a variety of ammunition, up to a full inch in calibre. A few were used by U.S. forces in Cuba in 1898 and in minor military operations around the world.

The mitrailleuse.   The French mitrailleuse was also a multibarreled weapon, but it used a loading plate that contained a cartridge for each of its 25 barrels. The barrels and the loading plate remained fixed, and a mechanism (operated by a crank) struck individual firing pins simultaneously or in succession. The mitrailleuse issued to the French army fired 11-millimetre Chassepot rifle ammunition. Weighing more than 2,000 pounds, it was mounted on a wheeled carriage and was usually employed in volley fire, all barrels discharging at once. French forces in the Franco-German War endeavoured to use it in a manner similar to artillery, but it was no match for breech-loading cannon firing explosive shells.

Tactical misuse of the mitrailleuse

Heavy machine guns.   Self-actuated machine guns, which operated under energy generated by a fired round, became militarily effective after the introduction of nitrocellulose propellants. These burned at a more controlled rate than did the older black-powder propellants, generating pressures that built up over a longer time. The first automatic weapons to take advantage of this were heavy guns firing the new, high-velocity rifle cartridges.

Recoil.   The first successful automatic machine gun was invented by Hiram Stevens Maxim, an American working in Europe. Beginning about 1884, he produced a number of weapons in which the bullet's recoil energy was employed to unlock the breechblock from the barrel, to extract and eject the fired case from the gun, and to store sufficient energy in a main spring to push the bolt forward, pick up a fresh round, load the chamber, and lock the piece. Both barrel and breechblock, locked together, recoiled a short distance to the rear; then the barrel was stopped and the block continued back alone. If the trigger

Imperial War Museum

Figure 13: A Maxim machine gun, belt-fed and water-cooled, operated by German infantrymen, World War I.

was held in firing position, the weapon would continue to fire until it expended all of its ammunition. Rounds were fed to the gun on belts, which could be clipped together to provide continuous fire, and overheating was solved by surrounding the barrel in a metal jacket in which water was circulated from a separate container.

Maxim's salesmen provided armies with guns in any calibre, usually matching their current rifle cartridge. In Britain, Maxim guns were first chambered for the .45-inch Martini-Henry cartridge, but, as issued in 1891, they fired the .303-inch smokeless-powder round of the Lee-Metford rifle. During the Russo-Japanese War (1904–05), the Russians used English-made Maxim guns chambered for their 7.62-millimetre Mosin-Nagant round. Their Model 1910 weighed about 160 pounds, including mount, water-cooling apparatus, and a protective steel shield for the gunner. The German Model 1908, chambered for the 7.92-millimetre Mauser cartridge, weighed 100 pounds with its sled mount. Such light weights, made possible because the cartridge was the sole source of power, allowed these weapons to be operated by special infantry units (see Figure 13).

Power of the Maxim gun

Machine guns of the Maxim type had a destructive power never seen before in warfare. In the 1890s, British infantry units used Maxim guns, fabricated under contract by Vickers Sons, to cut down hordes of poorly armed rebels in Africa and Afghanistan. In World War I, a few of them could cause thousands of casualties. Their defensive fire so limited the offensive power of infantry that the entire Western Front, from the Swiss border to the English Channel, became one vast siege operation.

Gas operation. Not all the early heavy machine guns were of the recoil-operated Maxim type. Gas operation was also employed. In this system a piston located in a cylinder below the barrel was driven to the rear by gas diverted from the barrel through a port. The piston unlocked the breechblock and sent the bolt back against the main spring; a new round was then picked up, moved into the chamber, and fired on the forward stroke.

The best-known gas-operated heavy machine gun was the Hotchkiss, introduced in France in 1892 and modified several times until the definitive version of 1914. It was air-cooled, but the barrel itself was heavy and provided with metal fins to increase heat radiation. A slower method of feeding ammunition by short strips instead of long belts also helped to keep the weapon from overheating. The Japanese used Hotchkiss guns chambered for their 6.5-millimetre round against Russia in 1904–05. In World War I, two French Hotchkiss guns firing 8-millimetre Lebel cartridges were said to have fired 75,-000 rounds each in the defense of Verdun and to have remained serviceable.

Blowback. A third principle of machine-gun operation was often called blowback. In this, the action and barrel were never locked rigidly together; the barrel did not move, nor was there a gas cylinder and piston. To prevent the breech from opening so early that propellant gases would rupture the spent cartridge case, the block was heavy and the main spring strong. Also, there was usually a linkage of parts not quite on centre to delay the actual opening. Finally, the barrel was shorter than usual, allowing the bullet and gases to leave the barrel quickly.

The Austrian Schwarzlose of 1907/12, firing eight-millimetre Mannlicher rounds, operated by delayed blowback. It was entirely satisfactory in combat during World War I.

Light machine guns. Heavy machine guns were satisfactory for defensive roles but were not really portable. A number of lighter machine guns (frequently called machine rifles or automatic rifles) began to be used in 1915. These included the British Lewis gun (invented in America but manufactured and improved in Great Britain), the French Chauchat, several German weapons, and the U.S. M1918 Browning automatic rifle (known as the BAR). Most, but not all, of these light weapons were gas-operated. Almost all were air-cooled. Generally, they fired from magazines rather than belts of ammunition because detachable magazines were more convenient and more easily transported. Weighing as little as 15 pounds, they were light enough to

be carried by one man and fired rifle-fashion or from a prone position.

After World War I, light machine guns virtually took over the functions of their heavier counterparts, although the older weapons continued in service around the world through World War II and for decades thereafter. In Germany, where heavy, water-cooled Maxim-type guns had been forbidden by the victorious Allies, an entirely new generation of light machine guns was introduced by the Maschinengewehr 1934 and 1942. Recoil-operated and fed 7.92-millimetre rifle ammunition on belts, these were equally effective when fired from bipods or when mounted on tripods for sustained fire. Firing at an extremely high rate (as high as 1,000 rounds per minute), they dealt with the overheating problem by being built with barrels that could be changed in seconds. The MG34 pioneered the quick-change mechanism, while the MG42, being fabricated largely of stamped sheet-metal parts welded and riveted together, could be made cheaply and quickly even in factories designed for automobile manufacture.

The MG34 and MG42

The Soviets began to issue their Degtyarev Pekhotny (DP) in 1933 and supplied it to Loyalist forces in the Spanish Civil War. In 1944 it was modified into the DPM. British infantry units fought World War II with the Bren, a .303-inch version of a weapon designed by the Czech weapons maker Václav Holek, and U.S. troops relied on the BAR. All were gas-operated and magazine-fed and weighed from slightly over 20 pounds to more than 30 pounds loaded. They fired slowly enough to deliver accurate bursts from their bipods, 350–600 rounds per minute.

After the war, with assault-rifle cartridges becoming standard issue, terms such as automatic rifle, light machine gun, and medium machine gun gave way to general-purpose machine gun (GPMG) and squad automatic weapon (SAW). Most GPMGs were chambered for the intermediate-size 7.62-millimetre cartridges of NATO and the Soviet Union, while SAWs fired small-calibre, high-velocity rounds such as the 5.56-millimetre NATO or the 5.45-millimetre Kalashnikov. Significant belt-fed GPMGs included the West German MG3, a modernized version of the MG42; the Mitrailleuse d'Appui Général (MAG), built by Fabrique Nationale of Belgium; the U.S.-made M60; and the Soviet Pulemyot Kalashnikova (PK). Of the SAWs, the most prominent were the belt- or magazine-fed Minimi, built by Fabrique Nationale, and the magazine-fed Ruchnoy Pulemyot Kalashnikova (RPK).

Large-calibre machine guns. With the eclipse of the early water-cooled machine guns, the term heavy was applied to machine guns firing cartridges of several times rifle calibre—most often .50 inch or 12.7 millimetres.

Even before World War I, fully automatic weapons were used with ammunition more powerful than rifle cartridges, but such ammunition was not necessary for infantry missions until foot soldiers encountered armoured vehicles. During the 1930s, many higher-powered weapons were adopted, although only two had outstanding success. One was the United States' M2 Heavy Barrel Browning. Essentially a .50-inch version of the .30-inch M1917 Browning (a Maxim-type machine gun produced too late to see much fighting in World War I), the M2 was still widely used throughout the noncommunist world decades after World War II. Its cartridge delivered bullets of various weights and types at high muzzle velocities, with roughly five to seven times the energy of full rifle-power ammunition. The weapon was recoil-operated and air-cooled, and it fired at about 450 rounds per minute. The Soviet 12.7-millimetre weapon, the Degtyarov-Shpagin Krupnokaliberny 1938 (DShK-38), was similar, but it was gas-operated. It went into wide use in Soviet-supplied countries. Both of these weapons, as well as their successors (such as the Soviets' Nikitin-Sokolov-Volkov, or NSV, machine gun), were used by infantry units on wheeled or tripod mounts, but they were also mounted on tanks to provide defensive fire against ground vehicles or aircraft (see Figures 24 and 25).

After 1945, several superheavy machine guns (more than .50 inch) were developed, mostly for antiaircraft use. The single most important was a 14.5-millimetre weapon first introduced by the Soviets for use in armoured vehicles. It was recoil-operated and belt-fed and had a barrel that

Heavy antiaircraft guns

could be changed quickly. Later it was fielded on a variety of wheeled carriages and was known as the Zenitnaya Protivovozdushnaya Ustanovka. The ZPU-4, a four-barreled version towed on a trailer, shot down many U.S. aircraft during that nation's involvement in the Vietnam War (1965–73) and remained in service throughout the Third World long afterward.   (J.We./J.F.G./E.C.E.)

PISTOLS

Since the 16th century, soldiers have carried handguns to supplement their basic shoulder weapons. However, because the firepower of pistols must be kept low in order to reduce them to manageable weight, and because only skilled soldiers can shoot them accurately beyond 10 yards, they have never been satisfactory military weapons. By World War II, pistols were issued principally to officers as a badge of rank and as a defensive weapon of last resort. Currently, they are most frequently carried by military police and other security personnel.

Revolvers. Until the mid-1840s most pistols were single-shot muzzle-loaders fired by wheel lock, flintlock, and percussion ignition systems. In 1835 Samuel Colt patented the first successful percussion revolver. In the frame of this weapon was a revolving cylinder drilled with several chambers (usually five or six), into which powder and ball (or combustible paper cartridges containing powder and ball) were loaded from the front. In the rear of each chamber a percussion cap was placed over a hollow nipple that directed the jet of flame to the powder when the cap was struck by the hammer. This type of revolver was eventually called "cap-and-ball." Where earlier revolvers required the shooter to line up a chamber with the barrel and cock the hammer in separate steps, Colt devised a single-action mechanical linkage that rotated the cylinder as the hammer was cocked with the thumb.

Colt dominated the manufacture of revolvers until the expiration of his U.S. patent in 1857. At that time two other Americans, Horace Smith and Daniel B. Wesson, produced the first cartridge revolver, based on a design purchased from Rollin White. Using rim-fire copper cartridges and eliminating the percussion-cap nipple, this weapon could be quickly loaded from the rear.

Double action When the Smith & Wesson patent expired in 1872, a host of new revolver designs appeared in the United States and Europe. The most important innovations were quick ejection of spent cartridges and double-action cocking. By linking the trigger to the hammer-cocking and cylinder-revolving mechanisms, double action permitted a pistol to be fired with a simple pull of the trigger. This mechanism was first introduced on a cap-and-ball revolver, the English Beaumont-Adams of 1855, but it was quickly adapted to cartridge revolvers. There were several mechanisms for removing spent cartridge cases. In the 1870s Smith & Wesson produced revolvers with hinged frames. When such a revolver was "broken open"—that is, when the barrel and cylinder were tipped down on the hinge away from the hammer and handgrip—an ejector rod, located in the middle of the cylinder but having a star-shaped head that radiated into each chamber, pushed out all the cartridges simultaneously. In the 1890s some Colt revolvers were made with solid frames but with cylinders that swung out to the side, where pushing an ejector rod forced out the cartridges.

By the end of the 19th century the revolver had reached its definitive form and its highest possible effectiveness as a military weapon. Indeed, from the 1880s through World War II, British officers carried such revolvers as the .45-inch Webley and the .38-inch Enfield, both of which were the hinged-frame design. The U.S. military adopted various revolvers, usually Colts or Smith & Wessons of .38-inch or .45-inch calibre, until 1911, when it switched to autoloading pistols.

Self-loaders. A high rate of fire was especially crucial to last-ditch, close-quarters defense, and, with handguns as well as shoulder arms, this meant automatic loading. Following Hiram Maxim's experiments with self-loading weapons (see *Machine guns*), automatic-pistol designs appeared in the last years of the 19th century.

In 1893 Ludwig Loewe & Company (later known as Deutsche Waffen- und Munitionsfabriken) introduced the first commercially viable self-loading pistol. Designed by an American, Hugo Borchardt, this 7.63-millimetre weapon operated on the principle of recoil. When the gun was fired, the barrel and breechblock, locked together by a "toggle-link" mechanism, slid back together along the top of the frame. The toggle, essentially a two-piece arm hinged in the middle but lying flat behind the breechblock, also recoiled for a short distance before it was forced to buckle upward at its hinge. This unlocked the breechblock from the barrel and allowed it to slide back on its own, extracting and ejecting the spent case, cocking the hammer, and compressing a coiled spring in the rear of the gun. The spring then pushed the breechblock forward, stripping a fresh cartridge from a magazine in the handgrip, and the toggle locked the breechblock once more against the barrel.

Borchardt's toggle and spring mechanisms were improved by a German, Georg Luger, who came up with the 7.65-millimetre (later 9-millimetre) Parabellum pistol. This was adopted by the German army in 1908.

In the United States and many parts of Europe, John M. Browning's handgun designs dominated the first half of the 20th century. In his .45-inch pistol, manufactured by Colt and adopted by the U.S. military in 1911, the barrel and breechblock were covered and locked together by a housing called the slide. When the gun was fired, the recoiling slide pulled the barrel back a short distance until the barrel was disengaged and returned to its forward position by a spring. The unlocked slide and breechblock continued back, ejecting the spent case and cocking the hammer, until a spring forced them forward while a fresh cartridge was picked up from a seven-round magazine in the grip. The M1911 Colt did not begin being replaced until 1987. Its successor, the nine-millimetre Italian Beretta, given the NATO designation M9, reflected post-1970 trends such as large-capacity magazines (15 shots in the Beretta), double-action triggers (which could snap the hammer without its having to be cocked manually or automatically), and ambidextrous safety levers.

Browning's Colt .45

GRENADE LAUNCHERS

Soldiers have always favoured grenades for the killing and stunning effect of their explosive power, but the effectiveness of hand grenades has always been limited to the distance they can be thrown. Extending the range of grenades requires that they be launched by some sort of infantry weapon.

Single shot. During World War I, most armies developed attachments for standard service rifles that permitted the launching of "rifle" grenades. However, although range was increased with these devices, accuracy remained poor. An effective answer was a shoulder-fired grenade launcher developed in the 1950s by the Springfield Armory. Resembling a single-shot, break-open, sawed-off shotgun, the M79 lobbed a 40-millimetre, 6-ounce (176-gram) high-explosive fragmentation grenade at a velocity of 250 feet per second to a maximum range of 400 yards. This covered the area between the longest range of hand-thrown grenades (30 to 40 yards) and the middle range of 60-millimetre mortars (300–400 yards).

The M79 employed a "high-low pressure system" developed by Germany during World War II. This involved an aluminum cartridge case with a sealed propellant chamber in front of the primer. The propellant chamber was perforated by a number of partially completed, carefully sized holes leading into a separate expansion chamber within the cartridge case. Upon firing, the high pressures created inside the propellant chamber flowed into the expansion chamber through the previously prepared holes. The resulting moderated gas pressure produced a low impulse that launched the grenade at an adequate velocity and with an acceptable recoil impulse.

The grenade round

M79 grenade launchers were made from 1961 to 1971 and saw a great deal of action in Vietnam. Production was terminated in favour of a launcher attachment for the M16 rifle.

Automatic fire. Grenade-launching machine guns also appeared during the Vietnam War. Instead of the thin-walled projectiles fired by the M79, these shot higher-

velocity cartridges. The weapons were first mounted on helicopters but afterward appeared on tripods and armoured vehicles. On these mounts, grenade-launching machine guns such as the U.S. Mark 19, firing 40-millimetre rounds, and the Soviet AGS-17, shooting 30-millimetre projectiles, frequently replaced or supplemented .50-inch heavy machine guns.

ANTITANK WEAPONS

Upon their introduction in World War I, tanks posed a very serious problem for foot soldiers. The Germans quickly reacted by introducing the 13-millimetre Tankgewehr ("Antitank Rifle"), a very large-scale single-shot version of the Mauser bolt-action rifle. British designers created the magazine-fed, bolt-action .55-inch Boys antitank rifle in the late 1930s, and the Soviets introduced 14.5-millimetre bolt-action and self-loading antitank rifles during World War II. The increasing thickness of tank armour soon made all of these infantry weapons obsolete, since kinetic-energy weapons that could penetrate tank armour became too heavy and produced too much recoil to be fired from the shoulder.

The search for a shoulder-fired antitank weapon took another turn with the application of a principle discovered in the 1880s by an American inventor, Charles E. Munroe. Munroe found that a hollow cone of explosive material, when detonated with its open end a few inches from metal plate, produced a jet of white-hot gases and molten steel that could penetrate many inches of the best armour. Utilizing the Munroe principle, various "shaped-charge" projectiles were first delivered during World War II by low-velocity, shoulder-held rocket launchers such as the bazooka (see below *Rockets and missile systems*) or by recoilless devices such as the German Panzerfaust ("Tank Fist," or "Tank Puncher"). Issued in the latter half of the war, the German weapon was a 30-inch-long, 1.75-inch-diameter tube containing a charge of gunpowder. A six-inch-diameter bomb, mounted on a stick with collapsible fins, was inserted into the front end, and the weapon, held over the shoulder or under the arm, was fired by a simple firing pin and percussion cap on the outside of the tube. The propellant gases blew a cap off of the rear of the tube, in effect canceling the recoil forces generated by the launching of the bomb, which could be lobbed to ranges of 30 to 100 yards. Its powerful shaped charge of RDX and TNT could penetrate any tank armour.

Following World War II, the Soviet military perfected the Panzerfaust-type recoilless launch mechanism in their Ruchnoy Protivotankovy Granatomet 2 (RPG-2), a "Light Antitank Grenade Launcher" featuring a reusable launcher that lobbed an 82-millimetre shaped-charge warhead more than 150 yards. After 1962, with their RPG-7, they combined recoilless launch with a rocket sustainer to deliver a five-pound warhead to targets beyond 500 yards. The Soviet RPGs became powerful weapons in the hands of guerrillas and irregular fighters in conflict against more conventionally armed and heavily armoured forces. As such, they were used by the Viet Cong to destroy U.S. armoured vehicles in Vietnam and by militiamen in the protracted conflicts of the Middle East (see Figure 14).

Other countries also developed small, shoulder-held recoilless launchers firing shaped-charge warheads. Some of them, such as the Swedish Miniman, came preloaded and were designed to be discarded after firing.   (E.C.E.)

Artillery

For three centuries after the perfection of cast-bronze cannon in the 16th century, few improvements were made in artillery pieces or their projectiles. Then, in the second half of the 19th century, there occurred a series of advances so brilliant as to render the artillery in use when the century closed probably 10 times as efficient as that which marked its opening. These remarkable developments took place in every aspect of gunnery: in the pieces, with the successful rifling of cannon bores; in the projectiles, with the adoption of more stable elongated shapes; and in the propellants, with the invention of more powerful and manageable gunpowders.

The RPG-7

These advances wrought a further transformation in the ever-changing nomenclature and classification of artillery pieces. Until the adoption of elongated projectiles, ordnance was classified according to the weight of the solid cast-iron ball a piece was bored to fire. But, because cylindrical projectiles weighed more than spheres of the same diameter, designation in pounds was abandoned, and the calibre of artillery came to be measured by the diameter of the bore in inches or millimetres. Cannon became the general term for large ordnance. A gun was a cannon designed to fire in a flat trajectory, a howitzer was a shorter piece designed to throw exploding shells in an arcing trajectory, and a mortar was a very short piece for firing at elevations of more than 45°.

Calibre by weight or by diameter

CANNONS

Rifled bores. In the middle years of the 19th century, smoothbore field artillery was placed at a disadvantage by the adoption of rifled small arms, which meant that infantry weapons could now outrange artillery. It therefore became vital to develop rifling for artillery weapons as well. The advantages of rifling were well known, but the technical difficulties of adapting the principle to heavy weapons were considerable. Several systems had been tried; these generally involved lead-coated projectiles that could engage shallow rifling grooves or projectiles fitted with studs that would fit into deeper rifling. None had proved adequate.

Breech loading. In 1854 William Armstrong, an English hydraulic engineer, designed an entirely new type of gun. Instead of simply boring out a solid piece of metal, Armstrong forged his barrel from wrought iron (later from steel). He then forged a succession of tubes and, by heating and shrinking, assembled them over the basic barrel so as to strengthen it in the area where the greatest internal pressure occurred. The barrel was rifled with a number of narrow, spiral grooves, and the projectile was elongated and coated with lead. The gun was loaded from the rear, the breech being closed by a "vent-piece" of steel that was dropped into a vertical slot and secured there by a large-diameter screw. The screw was hollow so as to make it lighter and facilitate loading.

In 1859 the British adopted the Armstrong system for field and naval artillery. During this same period, the Prussians had been testing guns made by Alfred Krupp, and in 1856 they adopted their first Krupp breechloader. This was made of a solid steel forging, bored and then rifled with a few deep grooves, and its breech was closed by a transverse sliding steel wedge. The Krupp projectile had a number of soft metal studs set into its surface, positioned so as to align with the rifling grooves. In both the Armstrong and Krupp guns, obturation—that is, the sealing of the breech against the escape of gas—was per-

formed by a soft metal ring let into the face of the vent piece or wedge. This pressed tightly against the chamber mouth to provide the required seal.

Meanwhile, the French adopted a muzzle-loading system designed by Treuille de Beaulieu, in which the gun had three deep spiral grooves and the projectile had soft metal studs. The gun was loaded from the muzzle by engaging the studs in the grooves before ramming the shell.

Armstrong guns were successful against Maoris in New Zealand and during the Opium Wars in China, but the development of ironclad ships in Europe demanded guns powerful enough to defeat armour, and the Armstrong gun's breech closure was not strong enough to withstand large charges of powder. Therefore, in 1865 the British adopted a muzzle-loading system similar to that of de Beaulieu, since only this would provide the required power and avoid the complications of sealing the breech.

Through the 1870s guns, particularly coastal-defense and naval guns, became longer so as to extract the utmost power from large charges of gunpowder. This made muzzle loading more difficult and gave a greater incentive to the development of an efficient breech-loading system.

The screw-
threaded
breech Various mechanisms were tried, but the one that supplanted all others was the interrupted screw, devised in France. In this system the rear end of the bore was screw-threaded, and a similarly screwed plug was used to close the gun. In order to avoid having to turn the plug several times before closure was effected, the plug had segments of its thread removed, while the gun breech had matching segments cut away. In this way the screwed segments of the plug could be slipped past smooth segments of the breech, and the plug slid to its full depth. Then the plug could be revolved part of a turn, sufficient for the remaining threads to engage with those in the breech.

In the earliest applications of this system, obturation was provided by a thin metal cup on the face of the breech-block; this entered the gun chamber and was expanded tightly against the walls by the explosion of the charge. In practice, the cup tended to become damaged, leading to leakage of gas and erosion of the chamber. Eventually a system devised by another French officer, Charles Ragon de Bange, became standard. Here the breechblock was in two pieces—a plug screwed with interrupted threads and having a central hole, and a "vent bolt" shaped like a mushroom. The stem of the bolt passed through the centre of the breechblock, and the "mushroom head" sat in front of the block. Between the mushroom head and the block was a pad of resilient material shaped to conform to the chamber mouth. On firing, the mushroom head was forced back, squeezing the pad outward so as to provide a gas-tight seal. This system, refined by a century of experience, became the principal method of obturation used with major-calibre artillery.

The alternative to this system was the sliding breechblock and metallic cartridge case pioneered by Krupp. Here the case expanded under the charge pressure and sealed against the chamber walls. As the pressure dropped, the case contracted slightly and could be withdrawn when the breechblock was opened. This system was embraced first by German gunmakers and later was widely used in all calibres up to 800 millimetres (about 31 inches). However, during World War II (1939–45), when the Germans were faced with metal shortages that threatened cartridge-case production, they developed a form of "ring obturation" so that bagged charges could be used. In this system an expandable metal ring was set into the face of the sliding breechblock, and its seating was vented in such a manner that some of the propellant gas was able to increase the pressure behind the ring and so force it into tighter contact. As improved in the postwar years, this system was adopted on a number of tank and artillery guns.

Gun construction. The lasting legacy of the Armstrong gun was the system of building up the gun from successive tubes, or "hoops"; this was retained in the rifled muzzle-loading system of the 1870s and was gradually adopted by other countries. Armstrong's method not only economized on material, by distributing metal in accordance with the pressures to be resisted, but it also strengthened the gun. An exception to the built-up system was practiced by

Krupp. He bored guns from solid steel billets, making the barrels in one piece for all but the very largest calibres. In the mid-19th century it was difficult to produce a flawless billet of steel, and a flawed gun would burst explosively, endangering the gunners. A wrought-iron gun, on the other hand, tended to split progressively, giving the gunners warning of an impending failure. This was enough to warrant the use of wrought iron for many years, until steel production became more reliable. Early steel
barrels

The next major advance in gun construction came in the 1890s with wire-winding, in which one or more hoops were replaced by steel wire wound tightly around the tube. This gave good compressive strength but no longitudinal strength, and the guns frequently bent. Beginning in the 1920s, wire-winding was abandoned in favour of "auto-frettaging," in which the gun tube was formed from a billet of steel and then subjected to intense internal pressure. This expanded the interior layers beyond their elastic limit, so that the outer layers of metal compressed the inner in a manner analogous to Armstrong's hoops but in a homogenous piece of metal.

Recoil control. Until the 1860s guns were simply allowed to recoil along with their carriages until they stopped moving, and they were then manhandled back into firing position. The first attempt at controlling recoil came with the development of traversing carriages for coastal defenses and fortress guns. These consisted of a platform, pivoted at the front and sometimes carried on wheels at the rear, upon which a wooden gun carriage rested. The surface of the platform sloped upward to the rear, so that when the gun was fired and the carriage slid backward up the platform, the slope and friction absorbed the recoil. After reloading, the carriage was manhandled down the sliding platform, assisted by gravity, until the gun was once more in firing position, or "in battery." To compensate for varying charges and, hence, varying recoil forces, the surface of the slide could be greased or sanded.

Control was improved by an American invention, the "compressor." This consisted of loose plates, fitted at the sides of the carriage and overlapping the sides of the slide, which were tightened against the slide by means of screws. Another arrangement was the placing of a number of metal plates vertically between the sides of the slide and a similar set of plates hanging from the carriage, so that one set interleaved the other. By placing screw pressure on the slide plates, the carriage plates were squeezed between them and thus acted as a brake on the carriage movement.

American designers added to this by adopting a hydraulic buffer, consisting of a cylinder and piston attached to the rear of the slide. The fired gun recoiled until it struck the piston rod, driving the piston into the cylinder against a body of water to absorb the shock. British designers then adapted this by attaching the buffer to the slide and the piston rod to the carriage. As the gun recoiled, it drove the piston through water inside the cylinder; meanwhile, a hole in the piston head permitted the water to flow from one side of the piston to the other, giving controlled resistance to the movement. Return to battery was still performed by manpower and gravity.

The final improvement came with the development of mechanical methods of returning the gun to battery, generally by the use of a spring. When the gun recoiled, it was braked by a hydraulic cylinder and at the same time compressed a spring. As recoil stopped, the spring reasserted itself, and the gun was propelled back into battery. From there it was a short step to using compressed air or nitrogen instead of a spring, and such "hydropneumatic" recoil-control systems became standard after their introduction by the French in 1897. Hydro-
pneumatic
recoil
control

Carriages and mountings. In 1850 carriages were broadly of two types. Field pieces were mounted on two-wheeled carriages with solid trails, while fortress artillery was mounted either on the "garrison standing carriage," a box-like structure on four small wheels, or on the platform-and-slide mounting previously described.

Coast guns. Coastal-defense artillery was the focus of most design attention in the 1870–95 period, since rapidly improving warships appeared to constitute the principal threat. The first major advance was a "disappearing car-

riage," in which the gun was mounted at the end of two arms that were hinged to a rotating base. In the firing position, a counterweight or hydraulic press held the arms vertical, so that the gun pointed over the edge of the pit in which the mounting was built. On firing, recoil drove the gun back, causing the arms to pivot and sink the gun into the pit out of sight of the enemy, where it could be reloaded in safety. This type of mounting, in various forms, was widely adopted, but it was gradually realized to be excessively complicated in view of the practical difficulty of a ship's gun being able to hit such a small target at long range. In most countries the disappearing mounting ceased to be built in the 1890s, though many of those already in position continued in use into the 1920s in Europe and into the 1940s in the United States.

In the 1890s the "barbette" mounting for coastal-defense guns became the preferred pattern. Here the mounting was in a shallow pit, protected from enemy fire, but the muzzle and upper shield were permanently in view, firing across a parapet that helped protect the gunners. This type of mounting was made practical by the development of hydraulic recoil control systems, which permitted the mounting to remain stationary while the gun, carried in a cradle, was allowed to recoil under control and then return to battery by spring or pneumatic power. The barbette remained the standard mounting for coastal-defense guns until their virtual disappearance after 1945.

The
French 75

Field artillery. Field carriage design entered a new era with the French 75-millimetre gun of 1897 (see Figure 15). This introduced an on-carriage hydropneumatic recoil-control system, a shield to protect the gunners, modern sighting, fixed ammunition, and a quick-acting breech mechanism—thus forming the prototype of what became known as the "quick-firing gun." The idea was quickly taken up in other countries, and, by the outbreak of World War I (1914–18), such weapons were standard in all armies. Mountings for larger guns—up to about 155 millimetres, or 6 inches, in calibre—simply enlarged this basic design.

Up to World War I, with horses providing the standard motive power, it was necessary to design heavy field artillery so that gun and mounting could be dismantled into components, each of which would be within the hauling capacity of a horse team. The gun then traveled in its various pieces until it was reassembled at the firing point. Steam traction was attempted by the British during the South African War (1899–1902), but it was found that tractors could not take guns into firing position, as their smoke and steam was visible to the enemy. The gradual improvement of the internal combustion engine promised a replacement for the horse, but it saw relatively little application until the middle of World War I—and then only for heavier types of artillery.

The type of carriage developed for very heavy weapons was exemplified by that used for the German

With screw-threaded breech, hydropneumatic recoil control, and metallic-cartridge ammunition, this was the archtypal quick-firing gun of the late 19th and early 20th centuries.

420-millimetre howitzers—collectively known as "Big Bertha"—that were used to reduce the fortresses of Liège, Belg., in 1914. The equipment was split into four units—barrel, mounting with recoil system, carriage, and ground platform—which were carried on four wagons pulled by Daimler-Benz tractors. A fifth wagon carried a simple hoist, which, erected over the gun position, was used to lift the components from their wagons and fit them together. As the Great War continued, heavier howitzers and longer-ranging guns were made so large that they could not be split into convenient loads for road movement. Thus, the railway mounting became a major type for guns and howitzers up to 520-millimetre calibre. The heaviest guns could be assembled on large mountings, which in turn could be carried on a number of wheels so as to distribute the load evenly onto a railway track. The most impressive railway gun built during the war was the German 210-millimetre "Paris Gun," which bombarded Paris from a range of 68 miles (109 kilometres) in 1918. Like many other railway guns, the Paris Gun was moved to its firing position by rail but, once in place, was lowered to a prepared ground platform.

Advances in carriage design after 1918 were relatively minor. The first was the general adoption of the split trail, in which two trail legs, opened to roughly 45°, were able to support a gun through a wider angle of traverse. Beginning in the 1960s came the gradual adoption of lightweight materials, culminating in the introduction by the British Vickers firm of a carriage built of titanium, which allowed a 155-millimetre howitzer to be helicopter-lifted. The 1960s also saw the introduction of auxiliary propulsion. Consisting of small motors that drove the wheels of towed guns, this permitted the gun to be moved from its firing position to a concealed or alternative position without calling up the towing vehicle. Propulsion motors also allowed the adoption of powered loading and ramming devices and powered assistance in opening trail legs and lowering platforms, thereby allowing the size of the crew to be reduced (see Figure 16).

Auxiliary
propulsion

Fire control. *Azimuth and range.* In the 1850s the tactics of artillery were simple: the gun was positioned well to the front and fired across open sights straight at the enemy. The general adoption after the 1880s of long-range rifles firing smokeless-powder rounds rendered this tactic hazardous, and the South African War and Russo-Japanese War (1904–05) brought about a change in policy. Guns had to be concealed from the enemy's view, and a system had to be found that allowed them to be aimed without a direct view of the target. The solution was the adoption of the "goniometric," or "panoramic," sight, which could be revolved in any direction and which was graduated in degrees relative to the axis of the gun bore. The gun's position and that of the target were marked on a map, and the azimuth (the number of degrees clockwise from due north) between the two was measured. A prominent local feature, or a marker placed some distance from the gun, was then selected as an aiming point, and the azimuth between this and the gun's position was also measured. Subtraction of one from the other produced the angle between a line to the aiming point and a line to the target. If this angle was then set on the goniometric sight and the gun shifted until the sight was laid on the aiming point, then the bore of the gun would be pointed at the target.

Once the azimuth was calculated, the range was arrived at by measuring off the map. This was then converted into an angle by consulting a table, calculated during development of the gun, on which ranges were tabulated against angles of elevation. The angle was then set on an adjustable spirit-level (a clinometer) attached to the elevating portion of the gun. Setting the elevation angle displaced a bubble from the level position, and elevating the gun until the bubble returned to the level position brought the gun bore to the correct elevation angle.

The combination of these two techniques was sufficient to fire a shell that would land close to the target. From there, a forward observer would instruct the gunner to change the azimuth and elevation until the shells struck the target. At this point the remaining guns of the battery, which would have followed the corrections and set

them on their own sights, would join in to carry out the
bombardment.

Predicted fire.   During World War I it became tactically
desirable to bombard an enemy position without alerting
him by ranging shots. This brought about the development
of "predicted fire."

While it is possible to determine azimuth and range from
a map with accuracy, it is difficult to predict the actual
Influences performance of a fired shell. The density and temperature
on the of the air through which the shell passes, the temperature
perfor- of the propelling charge, any variation in weight of the
mance of a shell from standard, any variation in the velocity of the
shell shell owing to gradual wear on the gun—these and similar
environmental changes can alter the performance of the
shell from its theoretical values. Beginning in the 1914–
18 period, these phenomena were studied and tables of
correction were developed, together with a meteorological
service that produced information upon which to base the
corrections. This technique of predicted fire was slowly
improved and was widely used during World War II, but
the corrections were an approximation at best, owing to
the simple tabular methods of applying the corrections. It
was not until the introduction of computers in the 1960s
that it became possible to apply corrections more accu-
rately and more rapidly.

Target acquisition.   Until the second half of the 20th
century, target acquisition—a vital part of fire control—
was almost entirely visual, relying upon ground observers.
This was augmented first by observation balloons and
then, in World War II, by light aircraft, the object of both
being to obtain better visual command over the battlefield.

In World War I two technical methods of targeting en-
emy gun positions were adopted—sound ranging and flash
spotting. In sound ranging, a number of microphones
were used to detect the sound waves of a gun being fired;
by measuring the time interval between the passing of
sound waves across different microphones, it was possible
to determine a number of rays of direction that, when
plotted on a map, would intersect at the position of the
enemy's gun. Flash spotting relied upon observers noting
the azimuth of gun flashes and plotting these so as to
obtain intersections. Both methods were highly effective,
and sound ranging remained a major means of target
acquisition for the rest of the century. Flash spotting fell
into disuse after 1945, owing to the general adoption of
flashless propellants, but in the late 1970s a new system
of flash spotting became possible, using infrared sensors
to detect the position of a fired gun.

Ammunition.   *Projectile, powder, and fuze.*   In 1850,
round solid shot and black powder were standard am-
munition for guns, while howitzers fired hollow powder-
filled shells ignited by wooden fuzes filled with slow-burn-
ing powder. The introduction of rifled ordnance allowed
the adoption of elongated projectiles, which, because of

their streamlined forms, were much less affected by wind
than round balls and, being decidedly heavier than balls
of like diameter, ranged much farther. Yet the changing
shape of projectiles did not at first affect their nature. For **Early**
example, the shrapnel shell, as introduced in the 1790s **shrapnel**
by the Englishman Henry Shrapnel, was a spherical shell
packed with a small charge of black powder and a number
of musket balls. The powder, ignited by a simple fuze,
opened the shell over concentrations of enemy troops, and
the balls, with velocity imparted by the flying shell, had
the effect of musket fire delivered at long range. When
rifled artillery came into use, the original Shrapnel design
was simply modified to suit the new elongated shells and
remained the standard field-artillery projectile, since it was
devastating against troops in the open.

Owing to the stabilizing spin imparted them by rifling
grooves, elongated projectiles flew much straighter than
balls, and they were virtually guaranteed to land point-
first. Utilizing this principle, elongated powder-filled shells
were fitted at the head with impact fuzes, which ignited
the powder charge on striking the target. This in turn led
to the adoption of powder-filled shells as antipersonnel
projectiles. In naval gunnery, elongated armour-piercing
projectiles initially were made of solid cast iron, with the
heads chilled during the casting process to make them
harder. Eventually, shells were made with a small charge
of powder, which exploded by friction at the sudden
deceleration of the shell upon impact. This was not an
entirely satisfactory arrangement, since the shells generally
exploded during their passage through the armour and not
after they had penetrated to the vulnerable workings of the
ship, but it was even less satisfactory to fit the shells with
impact fuzes, which were simply crushed upon impact.

Between 1870 and 1890 much work was done on the de-
velopment of propellants and explosives. Smokeless pow-
ders based on nitrocellulose (called ballistite in France and
cordite in Britain) became the standard propellant, and
compounds based on picric acid (under various names
such as lyddite in Britain, melinite in France, and shi-
mose in Japan) introduced modern high-explosive filling
for shells. These more stable compounds demanded the
development of fuzes adequate for armour-piercing shells,
since friction was no longer a reliable method of igniting
them. This was accomplished by fitting fuzes at the base
of the shells, where impact against armour would not
damage them but the shock of arrival would initiate them.

Time fuzes, designed to burst shrapnel shell over ground
forces at a particular point in the shell's trajectory, were
gradually refined. These usually consisted of a fixed ring
carrying a train of gunpowder, together with a similar but
moveable ring. The moveable ring allowed the time of
burning to be set by varying the point at which the fixed
ring ignited the moveable train and the point at which the
moveable train ignited the explosive.

During World War I these fuzes were fitted into antiaircraft shells, but it was discovered that they burned unpredictably at high altitudes. Powder-filled fuzes that worked under these conditions were eventually developed, but the Krupp firm set about developing clockwork fuzes that were not susceptible to atmospheric variations. These clockwork fuzes were also used for long-range shrapnel firing; inevitably, an undamaged specimen was recovered by the British, and the secret was out. By 1939 clockwork fuzes of various patterns, some using spring drive and some centrifugal drive, were in general use.

World War I also saw the development of specialized projectiles to meet various tactical demands. Smoke shells, filled with white phosphorus, were adopted for screening the activities of troops; illuminating shells, containing magnesium flares suspended by parachutes, illuminated the battlefield at night; gas shells, filled with various chemicals such as chlorine or mustard gas, were used against troops; incendiary shells were developed for setting fire to hydrogen-filled zeppelins. High explosives were improved, with TNT (trinitrotoluene) and amatol (a mixture of TNT and ammonium nitrate) becoming standard shell fillings.

World War II saw the general improvement of these shell types, though the same basic features were used and flashless propellants, using nitroguanidine and other organic compounds, gradually took over from the earlier simple nitrocellulose types. The proximity fuze was developed by joint British–American research and was adopted first for air defense and later for ground bombardment. Inside the proximity fuze was a small radio transmitter that sent out a continuous signal; when the signal struck a solid object, it was reflected and detected by the fuze, and the interaction between transmitted and received signals was used to trigger the detonation of the shell. This type of fuze increased the chances of inflicting damage on aircraft targets, and it also allowed field artillery to burst shells in the air at a lethal distance above ground targets without having to establish the exact range for the fuze setting.

The proximity fuze

After 1945 the proximity fuze was improved by the transistor and the integrated circuit. These allowed fuzes to be considerably reduced in size, and they also allowed the cost to be reduced, making it economically possible to have a combination proximity/impact fuze that would cater to almost all artillery requirements. Modern electronics also made possible the development of electronic time fuzes, which, replacing the mechanical clockwork type, could be more easily set and were much more accurate.

Nuclear shells, guided projectiles, and rocket assistance. Nuclear explosive was adapted to artillery by the United States' "Atomic Annie," a 280-millimetre gun introduced in 1953. This fired a 15-kiloton atomic projectile to a range of 17 miles, but, weighing 85 tons, it proved too cumbersome for use in the field and was soon obsolete. In its place, nuclear projectiles with yields ranging from 0.1 to 12 kilotons were developed for conventional 203-millimetre howitzers. Soviet major-calibre artillery was also provided with nuclear ammunition.

The 1970s saw the first moves toward "improved conventional munitions." These were artillery projectiles carrying a number of subprojectiles—antipersonnel bombs or mines or antitank mines—that could be fired from a gun and would be opened, by a time fuze, over the target area to distribute the submunitions. This increased the destructive power of an artillery shell by a large amount and allowed field artillery to place obstacles in the path of enemy tanks at a range of several miles. A further step was the development of guided projectiles. With the 155-millimetre Copperhead, a U.S. system, a forward observer could "illuminate" a target with laser light, a portion of which would be reflected and picked up by sensors in the approaching shell. The greater part of the shell's flight would be entirely ballistic, but in the last few hundred yards it would be controlled by fins or other means, which, guided by the laser detection system, would "home" the shell onto the target.

In order to improve the range of guns, rocket-assisted projectiles were developed, with moderate success, by the Germans during World War II, and they were the subject of further development in succeeding years. Rocket assis-

tance had certain drawbacks—notably, the loss of payload space in the shell to the rocket motor. A system designed to solve this problem was "base bleed," in which a small compartment in the base of the shell was filled with a piece of smokeless propellant. This would burn during flight, and the emergent gases would fill the vacuum left behind the shell in its passage through the air, reducing aerodynamic drag on the shell and improving the range by about 25 to 30 percent.

MORTARS

The mortar declined in importance during the 19th century but was restored by World War I, when short-range, high-trajectory weapons were developed to drop bombs into enemy trenches. Early designs in that conflict ranged from the 170-millimetre German Minenwerfer ("mine thrower"), which was almost a scaled-down howitzer, to primitive muzzle-loading devices manufactured from rejected artillery shells. The prototype of the modern mortar was a three-inch weapon developed by the Englishman Wilfred Stokes in 1915. This consisted of a smooth-bored tube, resting upon a baseplate and supported by a bipod, that had a fixed firing pin at its breech end. The bomb was a simple cylinder packed with explosive and fitted with a shotgun cartridge at the rear; its fuze was adapted from a hand grenade. When the bomb was dropped down the barrel of the mortar, it fired automatically as the shotgun cartridge struck the fixed firing pin. The bomb was unstable in flight but sufficiently accurate for its purpose, and it was soon replaced by a teardrop-shaped bomb with fins at the rear, which lent greater stability and accuracy. The Stokes mortar was rapidly adopted or copied by all belligerents.

The Stokes mortar

Some later mortars were built with rifled barrels, since these provided better sealing of the propellant gas and greater stability and accuracy owing to the spin imparted to the bomb. The difficulty here was to arrange for the bomb to be drop-loaded freely and yet engage the rifling once the propelling charge exploded. The U.S.-made M30, a 107-millimetre rifled mortar, used a saucer-shaped copper disk behind the bomb that flattened out into the rifling under gas pressure and provided obturation. In the 120-millimetre French Hotchkiss-Brandt type, a prerifled copper driving band, wrapped around the bomb, expanded under gas pressure and engaged the grooves in the barrel.

ANTIAIRCRAFT ARTILLERY

Heavy weapons and the problem of fire control. The development of antiaircraft guns began in 1909. The manufacture of suitable guns and mountings was not difficult at that time, but the fire-control problem, involving a target moving in three planes at high speed, was almost insoluble. The first fire-control system used complex gun sights that aimed the gun well in front of the target in order to give the shell time to reach it. The first projectiles were shrapnel, since scattered lead balls were sufficient to damage the aircraft of the day.

During World War I, attacks by German zeppelins led the British to produce incendiary shells. Forced to correct fire by visual methods, they fitted the shells with tracer devices, which, by leaving a trail of flame and smoke, indicated the shell's trajectory in the air. The French invented the "central post" system of fire control, in which an observing instrument in the centre of the battery calculated the aiming information, which was then passed on to the guns. This removed complex sights from the weapons and reduced the number of skilled operators required in a battery. Early warning of approaching aircraft was by visual means and acoustic devices.

In the 1920s work began on the design of "predictors," mechanical computers that could be given the course, height, and speed of the aircraft as well as the ballistic constants of the gun and could then calculate the gun data necessary to place the shell in the future position of the aircraft. These represented a significant advance in antiaircraft fire, but they still relied upon raw data provided by visual acquisition and tracking. In World War II, radar brought more accurate and timely acquisition and tracking, and the gradual adoption of electrical, rather

Predicting the position of aircraft

than mechanical, predictors produced more accurate fire control. Also, rapid-loading and fuze-setting devices were incorporated into gun mountings so that a high rate of fire could be achieved.

The proximity fuze removed the need for fuze setting and thus speeded up the rate of fire, until it was possible for guns of 90- to 100-millimetre calibre to fire at rates up to 60 rounds per minute. However, in the 1950s, when all these techniques were perfected, guided surface-to-air missiles became practical, and, in all major countries except for the Soviet Union, the use of medium and heavy air-defense guns ceased. (For a description of surface-to-air missiles, see below *Rockets and missile systems: Tactical guided missiles*.)

Light weapons. Light air-defense guns, of calibres from 20 to 40 millimetres, were developed in the 1930s for protection against dive bombers and low-level attack. The most famous of these was a 40-millimetre gun sold by the Swedish firm of Bofors. Virtually an enlarged machine gun, this fired small exploding shells at a rate of about 120 rounds per minute—fast enough to provide a dense screen of fragments through which the aircraft would have to fly. Fire control was largely visual, though some guns were equipped with predictors and power control.

The advent of lightweight missiles also threatened to render the light gun obsolete in the 1950s, but two decades later the development of electro-optical sights, using television and thermal-imaging technology and allied to computers and powered mountings, led to a resurgence of this class of weapon. In Egyptian hands in October 1973, the Soviet ZSU-23-4, consisting of four 23-millimetre guns mounted on a tracked vehicle, shot down many Israeli fighters over the Sinai Peninsula. The Bofors firm mounted its guns on wheeled vehicles, and the United States fielded a mobile system called Vulcan, which consisted of a six-barreled, Gatling-type gun firing 20-millimetre ammunition.

ANTITANK GUNS

The development of dedicated weapons for attacking tanks began in earnest in the 1930s. These were all in the 20- to 40-millimetre class, were mounted on light, two-wheeled, split-trail carriages, and were adequate against the tanks of the day. As tanks acquired heavier armour during World War II, so the guns became larger, eventually reaching 128 millimetres in calibre. The guns themselves did not generally demand new technology, but the development of ammunition had to break new ground.

The initial antitank projectile was a solid shot of hardened steel, and, in order to penetrate thicker armour, it was fired at higher and higher velocities. However, at a striking velocity of about 2,600 feet (800 metres) per second, steel shot shatters upon impact instead of penetrating. In order to overcome this, projectiles of tungsten carbide were used. The Germans designed a gun with a bore actually tapering in diameter from breech to muzzle, and for ammunition they constructed a projectile with a tungsten core and a soft metal body that would deform and squeeze in the reducing bore. The combination of reduced base area and constant gas pressure increased the projectile's velocity, and the "taper-bore" or "squeeze-bore" gun proved formidable. Guns with tapering calibres of 28/20, 41/29, and 75/55 millimetres were developed, but wartime shortages of tungsten led to their abandonment after 1942. In 1944 Britain perfected "discarding-sabot" projectiles, in which a tungsten core was supported in a conventional gun by a light metal sabot that split and fell free after leaving the muzzle, allowing the core to fly on at extremely high velocity.

An alternative method was to use high explosives in the form of shaped-charge or squash-head projectiles. The shaped charge was an explosive formed into a hollow cone and lined with heavy metal; upon detonation, the explosive gases and molten metal formed a high-velocity jet capable of punching through armour. The squash-head shell used a plastic explosive filling, which, deposited on the armour and then detonated, drove a shock wave through the plate. This resulted in the failure of the inner face and the ejection of a massive slab of metal into the tank.

Heavy antitank guns relying upon high-velocity projec-

High-velocity taper-bore guns

tiles largely fell into disuse after 1945, but the technology was perpetuated in the main armament mounted on tanks (see below *Tanks and armoured vehicles*). Explosive-energy projectiles were also used on tanks as well as on recoilless guns.

RECOILLESS GUNS

Military inventors were long attracted by the prospect of abolishing recoil, since achieving this meant doing away with the gun's heavy recoil system and lightening the carriage. The first to succeed was Commander Cleland Davis of the U.S. Navy, who in 1912 developed a gun with a single chamber and two opposite barrels. One barrel carried the projectile, the other an equal weight of grease and lead shot. The explosion of the central cartridge ejected both loads, and, since the recoils had the same weight and velocity, they canceled each other out and the gun remained stationary. Davis' idea was adopted in 1915 by the Royal Naval Air Service, which ordered guns of 40, 57, and 75 millimetres for arming aircraft against airships and submarines. Few were made, however, and there appears to be no record of their use in combat.

If the Davis principle were taken to its logical ends, the countershot could be half the weight and twice the velocity of the principal projectile or any other combination giving the same momentum; at its ultimate, the countershot could simply be a cloud of high-velocity gas. This was the system upon which recoilless guns of up to 105 millimetres were developed during World War II. The cartridge cases of these weapons had a weakened section that ruptured on firing, allowing about four-fifths of the propellant gas to be exhausted to the rear of the gun. There they passed through a venturi, a nozzle with a constricted portion that increased the gas velocity and so balanced the recoil generated by the projectile. The back-blast caused by the exhausted gases made these weapons difficult to emplace and conceal, but after 1945 they were universally adopted as light antitank weapons.   (I.V.H.)

The recoilless cartridge case

Rockets and missile systems

Rocket is a general term used broadly to describe a variety of jet-propelled missiles in which forward motion results from reaction to the rearward ejection of matter (usually hot gases) at high velocity. The propulsive jet of gases usually consists of the combustion products of solid or liquid propellants.

In a more restrictive sense, rocket propulsion is a unique member of the family of jet-propulsion engines that includes turbojet, pulse-jet, and ramjet systems. The rocket engine is different from these in that the elements of its propulsive jet (that is, the fuel and oxidizer) are self-contained within the vehicle. Therefore, the thrust produced is independent of the medium through which the vehicle travels, making the rocket engine capable of flight beyond the atmosphere or propulsion underwater. The turbojet, pulse-jet, and ramjet engines, on the other hand, carry only their fuel and depend on the oxygen content of the air for burning. For this reason, these varieties of jet engine are called air-breathing and are limited to operation within the Earth's atmosphere.

For the purposes of this article, a rocket engine is a self-contained (*i.e.*, non-air-breathing) propulsion system of the type described above, while the term rocket refers to any free-flight (unguided) missile of the types used since the beginning of rocketry. A guided missile is broadly any military missile that is capable of being guided or directed to a target after having been launched. Tactical guided missiles are shorter-ranged weapons designed for use in the immediate combat area. Long-range, or strategic, guided missiles are of two types, cruise and ballistic. Cruise missiles are powered by air-breathing engines that provide almost continuous propulsion along a low, level flight path. A ballistic missile is propelled by a rocket engine for only the first part of its flight; for the rest of the flight the unpowered missile follows an arcing trajectory, small adjustments being made by its guidance mechanism. Strategic missiles usually carry nuclear warheads, while tactical missiles usually carry high explosives.

MILITARY ROCKETS

Early history. There is no reliable early history of the "invention" of rockets. Most historians of rocketry trace the development to China, a land noted in ancient times for its fireworks displays. In 1232, when the Mongols laid siege to the city of K'ai-feng, capital of Honan province, the Chinese defenders used weapons that were described as "arrows of flying fire." There is no explicit statement that these arrows were rockets, but some students have concluded that they were because the record does not mention bows or other means of shooting the arrows. In the same battle, it is reported, the defenders dropped from the walls of the city a kind of bomb described as "heaven-shaking thunder." From these meagre references some students have concluded that by 1232 the Chinese had discovered black powder (gunpowder) and had learned to use it to make explosive bombs as well as propulsive charges for rockets. Drawings made in military documents much later show powder rockets tied to arrows and spears. The propulsive jet evidently added to the range of these weapons and acted as an incendiary agent against targets.

In the same century rockets appeared in Europe. There is indication that their first use was by the Mongols in the Battle of Legnica in 1241. The Arabs are reported to have used rockets on the Iberian Peninsula in 1249; and in 1288 Valencia was attacked by rockets. In Italy, rockets are said to have been used by the Paduans (1379) and by the Venetians (1380).

Construc-tion of early rockets

There are no details of the construction of these rockets, but they were presumably quite crude. The tubular rocket cases were probably many layers of tightly wrapped paper, coated with shellac. The propulsive charge was the basic black powder mixture of finely ground carbon (charcoal), potassium nitrate (saltpetre), and sulfur. The English scientist Roger Bacon wrote formulas for black powder about 1248 in his *Epistola*. In Germany a contemporary of Bacon, Albertus Magnus, described powder charge formulas for rockets in his book *De mirabilibus mundi*. The first firearms appeared about 1325; they used a closed tube and black powder (now referred to as gunpowder) to propel a ball, somewhat erratically, over varying distances. Military engineers then began to invent and refine designs for both guns and rockets.

By 1668, military rockets had increased in size and performance. In that year, a German colonel designed a rocket weighing 132 pounds (60 kilograms); it was constructed of wood and wrapped in glue-soaked sailcloth. It carried a gunpowder charge weighing 16 pounds. Nevertheless, the use of rockets seems to have waned, and for the next 100 years their employment in military campaigns appears to have been sporadic.

The 19th century. A revival commenced late in the 18th century in India. There Hyder Ali, prince of Mysore, developed war rockets with an important change: the use of metal cylinders to contain the combustion powder. Although the hammered soft iron he used was crude, the bursting strength of the container of black powder was much higher than the earlier paper construction. Thus a greater internal pressure was possible, with a resultant greater thrust of the propulsive jet. The rocket body was lashed with leather thongs to a long bamboo stick. Range was perhaps up to three-quarters of a mile (more than a kilometre). Although individually these rockets were not accurate, dispersion error became less important when large numbers were fired rapidly in mass attacks. They were particularly effective against cavalry and were hurled into the air, after lighting, or skimmed along the hard dry ground. Hyder Ali's son, Tippu Sultan, continued to develop and expand the use of rocket weapons, reportedly increasing the number of rocket troops from 1,200 to a corps of 5,000. In battles at Seringapatam in 1792 and 1799 these rockets were used with considerable effect against the British.

The news of the successful use of rockets spread through Europe. In England Sir William Congreve began to experiment privately. First, he experimented with a number of black-powder formulas and set down standard specifications of composition. He also standardized construction details and used improved production techniques. Also,

Congreve rockets

his designs made it possible to choose either an explosive (ball charge) or incendiary warhead. The explosive warhead was separately ignited and could be timed by trimming the fuse length before launching. Thus, air bursts of the warheads were feasible at different ranges.

Congreve's metal rocket bodies were equipped on one side with two or three thin metal loops into which a long guide stick was inserted and crimped firm. Weights of eight different sizes of these rockets ranged up to 60 pounds. Launching was from collapsible A-frame ladders. In addition to aerial bombardment, Congreve's rockets were often fired horizontally along the ground.

These side-stick-mounted rockets were employed in a successful naval bombardment of the French coastal city of Boulogne in 1806. The next year a massed attack, using hundreds of rockets, burned most of Copenhagen to the ground. During the War of 1812 between the United States and the British, rockets were employed on numerous occasions. The two best-known engagements occurred in 1814. At the Battle of Bladensburg (August 24) the use of rockets assisted British forces to turn the flank of the American troops defending Washington, D.C. As a result, the British were able to capture the city. In September the British forces attempted to capture Fort McHenry, which guarded Baltimore harbour. Rockets were fired from a specially designed ship, the Erebus, and from small boats. The British were unsuccessful in their bombardment, but on that occasion Francis Scott Key, inspired by the sight of the night engagement, wrote "The Star Spangled Banner," later adopted as the United States national anthem. "The rockets' red glare" has continued to memorialize Congreve's rockets ever since.

In 1815 Congreve further improved his designs by mounting his guide stick along the central axis. The rocket's propulsive jet issued through five equally spaced holes rather than a single orifice. The forward portion of the guide stick, which screwed into the rocket, was sheathed with brass to prevent burning. The centre-stick-mounted rockets were significantly more accurate. Also, their design permitted launching from thin copper tubes.

Maximum ranges of Congreve rockets were from one-half mile to two miles (0.8 to 3.2 kilometres), depending upon size. They were competitive in performance and cost with the ponderous 10-inch mortar and were vastly more mobile.

The next significant development in rocketry occurred about the middle of the 19th century. William Hale, a British engineer, invented a method of successfully eliminating the deadweight of the flight-stabilizing guide stick. By designing jet vents at an angle, he was able to spin the rocket. He developed various designs, including curved vanes that were acted upon by the rocket jet. These rockets, stabilized by means of spin, represented a major improvement in performance and ease of handling.

Hale rockets

Even the new rockets, however, could not compete with the greatly improved artillery with rifled bores. The rocket corps of most European armies were dissolved, though rockets were still used in swampy or mountainous areas that were difficult for the much heavier mortars and guns. The Austrian Rocket Corps, using Hale rockets, won a number of engagements in mountainous terrain in Hungary and Italy. Other successful uses were by the Dutch colonial services in Celebes and by Russia in a number of engagements in the Turkistan War.

Hale sold his patent rights to the United States in time for some 2,000 rockets to be made for the Mexican War, 1846–48. Although some were fired, they were not particularly successful. Rockets were used in a limited way in the American Civil War (1861–65), but reports are fragmentary, and apparently they were not decisive. The U.S. Ordnance Manual of 1862 lists 16-pound Hale rockets with a range of 1.25 miles.

In Sweden about the turn of the century, Wilhelm Unge invented a device described as an "aerial torpedo." Based upon the stickless Hale rocket, it incorporated a number of design improvements. One of these was a rocket motor nozzle that caused the gas flow to converge and then diverge. Another was the use of smokeless powder based on nitroglycerin. Unge believed that his aerial torpedoes would

be valuable as surface-to-air weapons against dirigibles. Velocity and range were increased, and about 1909 the Krupp armament firm of Germany purchased the patents and a number of rockets for further experimentation.

World War I and after. In the United States, meanwhile, Robert Hutchings Goddard was conducting theoretical and experimental research on rocket motors at Worcester, Mass. Using a steel motor with a tapered nozzle, he achieved greatly improved thrust and efficiency. During World War I Goddard developed a number of designs of small military rockets to be launched from a lightweight hand launcher. By switching from black powder to double-base powder (40 percent nitroglycerin, 60 percent nitrocellulose), a far more potent propulsion charge was obtained. These rockets were proving successful under tests by the U.S. Army when the Armistice was signed; they became the forerunners of the bazooka of World War II.

World War I actually saw little use of rocket weapons, despite successful French incendiary antiballoon rockets and a German trench-war technique by which a grappling hook was thrown over enemy barbed wire by a rocket with a line attached.

Many researchers besides Goddard used the wartime interest in rockets to push experimentation, the most noteworthy being Elmer Sperry and his son, Lawrence, in the United States. The Sperrys worked on a concept of an "aerial torpedo," a pilotless airplane, carrying an explosive charge, that would utilize gyroscopic, automatic control to fly to a preselected target. Numerous flight attempts were made in 1917, some successful. Because of early interest in military use, the U.S. Army Signal Corps organized a separate program under Charles F. Kettering in Dayton, Ohio, late in 1918. The Kettering design used a gyroscope for lateral control to a preset direction and an aneroid barometer for pitch (fore and aft) control to maintain a preset altitude. A high angle of dihedral (upward tilt) in the biplane wings provided stability about the roll axis. The aircraft was rail-launched. Distance to target was determined by the number of revolutions of a propeller. When the predetermined number of revolutions had occurred, the wings of the airplane were dropped off and the aircraft carrying the bomb load dropped on the target.

The limited time available to attack the formidable design problems of these systems doomed the programs, and they never became operational.

As World War II approached, minor and varied experimental and research activities on rockets and guided missiles were underway in a number of countries. But in Germany, under great secrecy, the effort was concentrated. Successful flights as high as one mile were made in 1931–32 with gasoline–oxygen-powered rockets by the German Rocket Society. Funds for such amateur activities were scarce, and the society sought support from the German army. The work of Wernher von Braun, a member of the society, attracted the attention of Captain Walter R. Dornberger. Von Braun became the technical leader of a small group developing liquid-propellant rockets for the German army. By 1937 the Dornberger–Braun team, expanded to hundreds of scientists, engineers, and technicians, moved its operations from Kummersdorf to Peenemünde, a deserted area on the Baltic coast. Here the technology for a long-range ballistic missile was developed and tested (see below *Strategic missiles*).

World War II. World War II saw the expenditure of immense resources and talent for the development of rocket-propelled weapons.

Barrage rockets. The Germans began the war with a lead in this category of weapon, and their 150-millimetre and 210-millimetre bombardment rockets were highly effective. These were fired from a variety of towed and vehicle-mounted multitube launchers, from launching rails on the sides of armoured personnel carriers, and, for massive bombardments, even from their packing crates. Mobile German rocket batteries were able to lay down heavy and unexpected concentrations of fire on Allied positions. The 150-millimetre Nebelwerfer, a towed, six-tube launcher, was particularly respected by U.S. and British troops, to whom it was known as the "Screaming

Pilotless airplanes (margin note)

The Nebelwerfer (margin note)

Figure 17: *Barrage rockets during the invasion of Mindoro, Phil., in December 1944.*
Launched in salvoes from landing craft, rockets smothered Japanese beach defenses as U.S. forces began the amphibious assault.
UPI/Bettmann Newsphotos

Meemie" or "Moaning Minnie" for the eerie sound made by the incoming rockets. Maximum range was more than 6,000 yards (5,500 metres).

A five-inch rocket with an explosive warhead was developed in Great Britain. Its range was two to three miles. These rockets, fired from specially equipped naval vessels, were used in heavy coastal bombardment prior to landings in the Mediterranean. Firing rates were 800–1,000 in less than 45 seconds from each ship.

A development of the U.S. Army was the Calliope, a 60-tube launching projector for 4.5-inch rockets mounted on a Sherman tank. The launcher was mounted on the tank's gun turret, and both azimuth (horizontal direction) and elevation were controllable. Rockets were fired in rapid succession (ripple-fired) to keep the rockets from interfering with one another as they would in salvo firing.

Other conventional rockets developed in the United States included a 4.5-inch barrage rocket with a range of 1,100 yards and a five-inch rocket of longer range. The latter was used extensively in the Pacific theatre of war, fired from launching barges against shore installations, particularly just before landing operations (see Figure 17). The firing rate of these flat-bottom boats was 500 per minute. Other rockets were used for smoke laying and demolition. The United States produced more than four million of the 4.5-inch rockets and 15 million of the smaller bazooka rockets during the war.

As far as is known, Soviet rocket development during World War II was limited. Extensive use was made of barrage, ripple-fired rockets. Both A-frame and truck-mounted launchers were used. The Soviets mass-produced a 130-millimetre rocket known as the Katyusha. From 16 to 48 Katyushas were fired from a boxlike launcher known as the Stalin Organ, mounted on a gun carriage.

The bazooka. Beginning in mid-1940, Clarence N. Hickman, who had worked with Robert Goddard during World War I, supervised the development of a refined design of the hand-launched rocket. The new rocket, about 20 inches (50 centimetres) long, 2.36 inches in diameter, and weighing 3.5 pounds, was fired from a steel tube that became popularly known as the bazooka. Designed chiefly for use against tanks and fortified positions at short ranges (up to 600 yards), the bazooka surprised the Germans when it was first used in the North African landings of 1942. Although the rocket traveled slowly, it carried a potent shaped-charge warhead that gave infantrymen the striking power of light artillery.

The German counterpart of the bazooka was a light 88-millimetre rocket launcher known as Panzerschreck ("Tank Terror") or Ofenrohr ("Stovepipe").

Antiaircraft rockets. During World War II high-altitude bombing above the range of antiaircraft guns necessitated the development of rocket-powered weapons.

In Great Britain, initial effort was aimed at achieving the equivalent destructive power of the three-inch and later the 3.7-inch antiaircraft gun. Two important innovations were introduced by the British in connection with the three-inch rocket. One was a rocket-propelled aerial-defense system. A parachute and wire device was rocketed aloft, trailing a wire that unwound at high speed from a bobbin on the ground with the object of snagging the aircraft's propellers or shearing off the wings. Altitudes as high as 20,000 feet were attained. The other device was a type of proximity fuze using a photoelectric cell and thermionic amplifier. A change in light intensity on the photocell caused by light reflected from a nearby airplane (projected on the cell by means of a lens) triggered the explosive shell.

Wire-trailing rockets

The only significant antiaircraft rocket development by the Germans was the Taifun. A slender, six-foot, liquid-propellant rocket of simple concept, the Taifun was intended for altitudes of 50,000 feet. The design embodied coaxial tankage of nitric acid and a mixture of organic fuels, but the weapon never became operational.

Aerial rockets. Britain, Germany, the Soviet Union, Japan, and the United States all developed airborne rockets for use against surface as well as aerial targets. These were almost invariably fin-stabilized because of the effective aerodynamic forces when launched at speeds of 250 miles per hour and more. Tube launchers were used at first, but later straight-rail or zero-length launchers, located under the wings of the airplane, were employed.

One of the most successful of the German rockets was the 50-millimetre R4M. The tail fins remained folded until launch, facilitating close loading arrangements.

The U.S. achieved great success with a 4.5-inch rocket, three or four of which were carried under each wing of Allied fighter planes. These rockets were highly effective against motor columns, tanks, troop and supply trains, fuel and ammunition depots, airfields, and barges.

A variation on the airborne rocket was the addition of rocket motors and fins to conventional bombs. This had the effect of flattening the trajectory, extending the range, and increasing velocity at impact, useful against concrete bunkers and hardened targets. These weapons were called glide bombs, and the Japanese had 100-kilogram and 370-kilogram (225-pound and 815-pound) versions. The Soviet Union employed 25- and 100-kilogram versions, launched from the IL-2 Stormovik attack aircraft.

Postwar. After World War II, unguided, folding-fin rockets fired from multiple-tube pods became a standard air-to-ground munition for ground-attack aircraft and helicopter gunships. Though not as accurate as guided missiles or gun systems, they could saturate concentrations of troops or vehicles with a lethal volume of fire. Many ground forces continued to field truck-mounted, tube-launched rockets that could be fired simultaneously in salvos or ripple-fired in rapid succession (see Figure 18). Such artillery rocket systems, or multiple-launch rocket systems, generally fired rockets of 100 to 150 millimetres in diameter and had ranges of 12 to 18 miles. The rockets carried a variety of warheads, including high explosive, antipersonnel, incendiary, smoke, and chemical.

Ballistic rockets

The Soviet Union and the United States built unguided ballistic rockets for about 30 years after the war. In 1955 the U.S. Army began deployment of the Honest John in western Europe, and from 1957 the Soviet Union built a series of large, spin-stabilized rockets, launched from mobile transporters, given the NATO designation FROG (free rocket over ground). These missiles, from 25 to 30 feet long and two to three feet in diameter, had ranges of 20 to 45 miles and could be nuclear-armed. Egypt and Syria fired many FROG missiles during the opening salvos of the Arab–Israeli War of October 1973, as did Iraq in its war with Iran in the 1980s, but in the 1970s large rockets were phased out of the superpowers' front line in favour

of inertially guided missiles such as the U.S. Lance and the Soviet SS-21 Scarab.   (F.C.D.III/Ed.)

TACTICAL GUIDED MISSILES

Guided missiles were a product of post-World War II developments in electronics, computers, sensors, avionics, and, to only a slightly lesser degree, rocket and turbojet propulsion and aerodynamics. Although tactical, or battle-field, guided missiles were designed to perform many different roles, they were bound together as a class of weapon by similarities in sensor, guidance, and control systems. Control over a missile's direction was most commonly achieved by the deflection of aerodynamic surfaces such as tail fins; reaction jets or rockets and thrust-vectoring were also employed. But it was in their guidance systems that these missiles gained their distinction, since the ability to make down-course corrections in order to seek or "home" onto a target separated guided missiles from purely ballistic weapons such as free-flight rockets and artillery shells.

Control methods

Guidance methods. The earliest guided missiles used simple command guidance, but within 20 years of World War II virtually all guidance systems contained autopilots or autostabilization systems, frequently in combination with memory circuits and sophisticated navigation sensors and computers. Five basic guidance methods came to be used, either alone or in combination: command, inertial, active, semiactive, and passive.

Command. Command guidance involved tracking the projectile from the launch site or platform and transmitting commands by radio, radar, or laser impulses or along thin wires or optical fibres. Tracking might be accomplished by radar or optical instruments from the launch site or by radar or television imagery relayed from the missile. The earliest command-guided air-to-surface and antitank munitions were tracked by eye and controlled by hand; later the naked eye gave way to enhanced optics and television tracking, which often operated in the infrared range and issued commands generated automatically by computerized fire-control systems. Another early command guidance method was beam riding, in which the missile sensed a radar beam pointed at the target and automatically corrected back to it. Laser beams were later used for the same purpose. Also using a form of command guidance were television-guided missiles, in which a small television camera mounted in the nose of the weapon beamed a picture of the target back to an operator who sent commands to keep the target centred in the tracking screen until impact. A form of command guidance used from the 1980s by the U.S. Patriot surface-to-air system was called track-via-missile. In this system a radar unit in the missile tracked the target and transmitted relative bearing and velocity information to the launch site, where control systems computed the optimal trajectory for intercepting the target and sent appropriate commands back to the missile.

Inertial. Inertial guidance was installed in long-range ballistic missiles in the 1950s but, with advances in miniaturized circuitry, microcomputers, and inertial sensors, it became common in tactical weapons after the 1970s. Inertial systems involved the use of small, highly accurate gyroscopic platforms to continuously determine the position of the missile in space. These provided inputs to guidance computers, which used the position information in addition to inputs from accelerometers or integrating circuits to calculate velocity and direction. The guidance computer, which was programmed with the desired flight path, then generated commands to maintain the course.

An advantage of inertial guidance was that it required no electronic emissions from the missile or launch platform that could be picked up by the enemy. Many antiship missiles and some long-range air-to-air missiles, therefore, used inertial guidance to reach the general vicinity of their targets and then active radar guidance for terminal homing. Passive-homing antiradiation missiles, designed to destroy radar installations, generally combined inertial guidance with memory-equipped autopilots to maintain their trajectory toward the target in case the radar stopped transmitting.

Tactical uses of inertial guidance

Active. With active guidance, the missile would track

its target by means of emissions that it generated itself. Active guidance was commonly used for terminal homing. Examples were antiship, surface-to-air, and air-to-air missiles that used self-contained radar systems to track their targets. Active guidance had the disadvantage of depending on emissions that could be tracked, jammed, or tricked by decoys.

Semiactive. Semiactive guidance involved illuminating or designating the target with energy emitted from a source other than the missile; a seeker in the projectile that was sensitive to the reflected energy then homed onto the target. Like active guidance, semiactive guidance was commonly used for terminal homing. In the U.S. Hawk and Soviet SA-6 Gainful antiaircraft systems, for example, the missile homed in on radar emissions transmitted from the launch site and reflected off the target, measuring the Doppler shift in the reflected emissions to assist in computing the intercept trajectory. (SA-6 Gainful is a designation given by NATO to the Soviet missile system. In this section, missile systems and aircraft of the former Soviet Union are referred to by their NATO designations.) The AIM-7 Sparrow air-to-air missile of the U.S. Air Force used a similar semiactive radar guidance method. Laser-guided missiles also could use semiactive methods by illuminating the target with a small spot of laser light and homing onto that precise light frequency through a seeker head in the missile.

With semiactive homing the designator or illuminator might be remote from the launch platform. The U.S. Hellfire antitank missile, for example, used laser designation by an air or ground observer who could be situated many miles from the launching helicopter.

Passive. Passive guidance systems neither emitted energy nor received commands from an external source; rather, they "locked" onto an electronic emission coming from the target itself. The earliest successful passive "Heat-homing munitions were "heat-seeking" air-to-air missiles seeking" that homed onto the infrared emissions of jet engine missiles exhausts. The first such missile to achieve wide success was the AIM-9 Sidewinder developed by the U.S. Navy in the 1950s. Many later passive homing air-to-air missiles homed onto ultraviolet radiation as well, using on-board guidance computers and accelerometers to compute optimal intercept trajectories. Among the most advanced passive homing systems were optically tracking munitions that could "see" a visual or infrared image in much the same way as the human eye does, memorize it by means of computer logic, and home onto it. Many passive homing systems required target identification and lock-on by a human operator prior to launch. With infrared antiaircraft missiles, a successful lock-on was indicated by an audible tone in the pilot's or operator's headset; with television or imaging infrared systems, the operator or pilot acquired the target on a screen, which relayed data from the missile's seeker head, and then locked on manually.

Passive guidance systems benefited enormously from a miniaturization of electronic components and from advances in seeker-head technology. Small, heat-seeking, shoulder-fired antiaircraft missiles first became a major factor in land warfare during the final stages of the Vietnam War, with the Soviet SA-7 Grail playing a major role in neutralizing the South Vietnamese Air Force in the final communist offensive in 1975. Ten years later the U.S. Stinger and British Blowpipe proved effective against Soviet aircraft and helicopters in Afghanistan, as did the U.S. Redeye in Central America.

Guided-missile systems. The principal categories of tactical guided missiles are antitank and assault, air-to-surface, air-to-air, antiship, and surface-to-air. Distinctions between these categories were not always clear, the launching of both antitank and infantry antiaircraft missiles from helicopters being a case in point.

Antitank and guided assault. One of the most important categories of guided missile to emerge after World War II was the antitank, or antiarmour, missile. The guided assault missile, for use against bunkers and structures, was closely related. A logical extension of unguided infantry antitank weapons carrying shaped-charge warheads for penetrating armour, guided antitank missiles

acquired considerably more range and power than their shoulder-fired predecessors. While originally intended for issue to infantry formations for self-protection, the tactical flexibility and utility of guided antitank missiles led to their installation on light trucks, on armoured personnel carriers, and, most important, on antitank helicopters.

The first guided antitank missiles were controlled by elec- Early wire-tronic commands transmitted along extremely thin wires guided played out from a spool on the rear of the missile. Pro- missiles pelled by solid-fuel sustainer rockets, these missiles used aerodynamic fins for lift and control. Tracking was visual, by means of a flare in the missile's tail, and guidance commands were generated by a hand-operated joystick. In operating these missiles, the gunner simply superimposed the tracking flare on the target and waited for impact. The missiles were typically designed to be fired from their carrying containers, with the total package small enough to be carried by one or two men. Germany was developing weapons of this kind at the end of World War II and may have fired some in battle.

After the war French engineers adapted the German technology and developed the SS-10/SS-11 family of missiles. The SS-11 was adopted by the United States as an interim helicopter-fired antitank missile pending the development of the TOW (for tube-launched, optically tracked, wire-guided) missile. Because it was designed for greater range and hitting power, TOW was mounted primarily on vehicles and, particularly, on attack helicopters. Helicopter-fired antitank missiles were first used in combat when the U.S. Army deployed several TOW-equipped UH-1 "Hueys" to Vietnam in response to the 1972 communist Easter offensive. TOW was the principal U.S. antiarmour munition until Hellfire, a more sophisticated helicopter-fired missile with semiactive laser and passive infrared homing, was mounted on the Hughes AH-64 Apache attack helicopter in the 1980s.

The British Swingfire and the French-designed, internationally marketed MILAN (*missile d'infanterie léger antichar,* or "light infantry antitank missile") and HOT (*haut subsonique optiquement téléguidé tiré d'un tube,* or "high-subsonic, optically teleguided, tube-fired") were similar in concept and capability to TOW.

The Soviets developed an entire family of antitank guided missiles beginning with the AT-1 Snapper, the AT-2 Swatter, and the AT-3 Sagger. The Sagger, a relatively small missile designed for infantry use on the lines of the original German concept, saw use in Vietnam and was used with conspicuous success by Egyptian infantry in the Suez Canal crossing of the 1973 Arab-Israeli War. The AT-6 Spiral, a Soviet version of TOW and Hellfire, became the principal antiarmour munition of Soviet attack helicopters.

Many antitank missile systems of later generations transmitted guidance commands by radio rather than by wire, and semiactive laser designation and passive infrared homing also became common. Guidance and control methods were more sophisticated than the original visual tracking and manual commands. TOW, for example, required the gunner simply to centre the reticle of his optical sight on the target, and the missile was tracked and guided automatically. Extremely thin optical fibres began to replace wires as a guidance link in the 1980s.

Air-to-surface. The United States began to deploy tactical air-to-surface guided missiles as a standard aerial munition in the late 1950s. The first of these was the AGM-12 (for aerial guided munition) Bullpup, a rocket-powered weapon that employed visual tracking and radio-transmitted command guidance. The pilot controlled the missile by means of a small side-mounted joystick and guided it toward the target by observing a small flare in its tail. Though Bullpup was simple and accurate, the delivery aircraft had to continue flying toward the target until the weapon struck—a vulnerable maneuver. The 250-pound (115-kilogram) warhead on the initial version of Bullpup proved inadequate for "hard" targets such as reinforced concrete bridges in Vietnam, and later versions had a 1,000-pound warhead. The rocket-powered AGM- Antiradar 45 Shrike antiradiation missile was used in Vietnam to missiles attack enemy radar and surface-to-air sites by passively

homing onto their radar emissions. The first missile of its kind used in combat, the Shrike had to be tuned to the desired radar frequency before flight. Because it had no memory circuits and required continuous emissions for homing, it could be defeated by simply turning off the target radar. Following the Shrike was the AGM-78 Standard ARM (antiradiation munition), a larger and more expensive weapon that incorporated memory circuits and could be tuned to any of several frequencies in flight. Also rocket-propelled, it had a range of about 35 miles (55 kilometres). Faster and more sophisticated still was the AGM-88 HARM (high-speed antiradiation missile), introduced into service in 1983.

Replacing the Bullpup as an optically tracked missile was the AGM-64/65 Maverick family of rocket-powered missiles. Early versions used television tracking, while later versions employed infrared, permitting the fixing of targets at longer ranges and at night. The self-contained guidance system incorporated computer logic that enabled the missile to lock onto an image of the target once the operator had identified it on his cockpit television monitor. Warheads varied from a 125-pound shaped charge for use against armour to high-explosive blast charges of 300 pounds.

Though less was known about them, the Soviets fielded an extensive array of air-to-surface missiles equivalent to the Bullpup and Maverick and to the Hellfire antitank missile. Notable among these was the radio-command-guided AS-7 Kerry, the antiradar AS-8 and AS-9, and the television-guided AS-10 Karen and AS-14 Kedge (the last with a range of about 25 miles). These missiles were fired from tactical fighters such as the MiG-27 Flogger and attack helicopters such as the Mi-24 Hind and Mi-28 Havoc.

Air-to-air. Developed in 1947, the radar-guided, subsonic Firebird was the first U.S. guided air-to-air missile. It was rendered obsolete within a few years by supersonic missiles such as the AIM-4 (for air-intercept missile) Falcon, the AIM-9 Sidewinder, and the AIM-7 Sparrow. The widely imitated Sidewinder was particularly influential. Early versions, which homed onto the infrared emissions from jet engine tailpipes, could approach only from the target's rear quadrants. Later versions, beginning with the AIM-9L, were fitted with more sophisticated seekers sensitive to a broader spectrum of radiation. These gave the missile the capability of sensing exhaust emissions from the side or front of the target aircraft (see Figure 41). Driven by the requirements of supersonic combat during the 1960s, the ranges of such missiles as the Sidewinder increased from about two miles to 10–15 miles. The AIM-54 Phoenix, a semiactive radar missile with active radar terminal homing introduced by the U.S. Navy in 1974, was capable of ranges in excess of 100 miles. Fired from the F-14 Tomcat, it was controlled by an acquisition, tracking, and guidance system that could engage up to six targets simultaneously. Combat experience in Southeast Asia and the Middle East produced increased tactical sophistication, so that fighter aircraft were routinely armed with several kinds of missile to deal with a variety of situations. U.S. carrier-based fighters, for instance, carried both heat-seeking Sidewinders and radar-homing Sparrows. Meanwhile, the Europeans developed such infrared-homing missiles as the British Red Top and the French Magic, the latter being a short-range (one-quarter to four miles) highly maneuverable equivalent of the Sidewinder.

The Soviets fielded an extended series of air-to-air missiles, beginning in the 1960s with the AA-1 Alkali, a relatively primitive semiactive radar missile, the AA-2 Atoll, an infrared missile closely modeled after the Sidewinder, and the AA-3 Anab, a long-range, semiactive radar-homing missile carried by air-defense fighters. The AA-5 Ash was a large, medium-range radar-guided missile, while the AA-6 Acrid was similar to the Anab but larger and with greater range. The AA-7 Apex, a Sparrow equivalent, and the AA-8 Aphid, a relatively small missile for close-in use, were introduced during the 1970s. Both used semiactive radar guidance, though the Aphid was apparently produced in an infrared-homing version as well. The long-range, semiactive radar-guided AA-9 Amos appeared in the mid-1980s; it was associated with the MiG-

31 Foxhound interceptor, much as the U.S. Phoenix was associated with the F-14. The Foxhound/Amos combination may have been fitted with a look-down/shoot-down capability, enabling it to engage low-flying targets while looking downward against a cluttered radar background. The AA-10 Alamo, a medium-range missile similar to the Amos, apparently had passive radar guidance designed to home onto carrier-wave emissions from U.S. aircraft firing the semiactive radar-homing Sparrow. The AA-11 Archer was a short-range missile used in combination with the Amos and Alamo.

Improvements in air-to-air missiles included the combined use of several methods of guidance for greater flexibility and lethality. Active radar or infrared terminal homing, for example, were often used with semiactive radar guidance in midcourse. Also, passive radar homing, which became an important means of air-to-air guidance, was backed up by inertial guidance for mid-course and by an alternate terminal homing method in case the target aircraft shut off its radar. Sophisticated optical and laser proximity fuzes became common; these were used with directional warheads that focused their blast effects toward the target. Tactical demands combined with advancing technology to channel the development of air-to-air missiles into three increasingly specialized categories: large, highly sophisticated long-range air-intercept missiles, such as the Phoenix and Amos, capable of ranges from 40 to 125 miles; short-range, highly maneuverable (and less expensive) "dogfighter" missiles with maximum ranges of six to nine miles; and medium-range missiles, mostly using semiactive radar homing, with maximum ranges of 20 to 25 miles. Representative of the third category was the AIM-120 AMRAAM (for advanced medium-range air-to-air missile), jointly developed by the U.S. Air Force and Navy for use with NATO aircraft. AMRAAM combined inertial mid-course guidance with active radar homing (see Figure 41).

Antiship. Despite their different methods of delivery, antiship missiles formed a coherent class largely because they were designed to penetrate the heavy defenses of warships.

The Hs-293 missiles developed by Germany during World War II were the first guided antiship missiles. Though accurate, they required the delivery aircraft to stay on the same line of sight as the weapon and target; the resultant flight paths were predictable and highly vulnerable, and the Allies quickly developed effective defenses.

Partly because Britain and the United States relied on carrier-based aircraft armed with conventional torpedoes, bombs, and unguided rockets to attack naval targets, antiship missiles at first received little emphasis in the West after the war. The Soviets, however, saw antiship missiles as a counter to Western naval superiority and developed an extensive range of air- and surface-launched antiship missiles, beginning with the AS-1 Kennel. The destruction of an Israeli destroyer by two SS-N-2 Styx missiles fired by Soviet-supplied Egyptian missile boats in October 1967 demonstrated the effectiveness of the Soviet systems, and the Western powers developed their own guided missiles. The resultant systems began entering service in the 1970s and first saw combat in 1982, during the Falkland Islands War. In that conflict the British Sea Skua, a small, rocket-powered, sea-skimming missile with semiactive radar homing, weighing about 325 pounds, was fired successfully from helicopters, while the Argentines sank a destroyer and a containership and damaged another destroyer with the solid-rocket-powered, active radar-homing French Exocet, fired from both aircraft and ground launchers. The Exocet weighed about 1,500 pounds and had an effective range of 35 to 40 miles.

The Exocet was one of a number of Western antiship missiles of the same general kind. Guidance was mostly by active radar, often supplemented in mid-course by inertial autopilots and in terminal flight by passive radar and infrared homing. Although designed for use from carrier-based attack aircraft, missiles of this sort were also carried by bombers and coastal patrol aircraft and were mounted on ship- and land-based launchers. The most important U.S. antiship missile was the turbojet-powered Harpoon,

Margin notes:
The Sidewinder

Increasing combat range

The Harpoon and Sea Eagle

which weighed about 1,200 pounds in its air-launched version and had a 420-pound warhead. Employing both active and passive radar homing, this missile could be programmed for sea-skimming attack or a "pop-up and dive" maneuver to evade a ship's close-in defense systems. The turbojet-powered British Sea Eagle weighed somewhat more than the Harpoon and employed active radar homing. The West German Kormoran was also an air-launched missile. The Norwegian Penguin, a rocket-powered missile weighing between 700 and 820 pounds and employing technology derived from the U.S. Maverick air-to-surface missile, had a range of about 17 miles and supplemented its active radar guidance with passive infrared homing. The Penguin was exported widely for fighter-bomber, attack boat, and helicopter use. The Israeli Gabriel, a 1,325-pound missile with a 330-pound warhead launched from both aircraft and ships, employed active radar homing and had a range of 20 miles.

The U.S. Navy Tomahawk defined a separate category of antiship missile: it was a long-range, turbofan-powered cruise missile first developed as a strategic nuclear delivery system (see below *Strategic missiles*). Tomahawk was carried by surface vessels and submarines in both ground-attack and antiship versions. The antiship version, equipped with a modified Harpoon guidance system, had a range of 275 miles. Only 20 feet long and 20.5 inches (53 centimetres) in diameter, the Tomahawk was fired from its launch tubes by a solid-fueled booster and cruised at subsonic speeds on flip-out wings.

For short-range antiship warfare, the Soviet Union deployed its AS series, 7, 8, 9, 10, and 14 air-to-surface missiles. Long-range antiship missiles designed for use from bomber and patrol aircraft included the 50-foot, swept-wing AS-3 Kangaroo, introduced in 1961 with a range exceeding 400 miles. The AS-4 Kitchen, a Mach-2 (twice the speed of sound) rocket-powered missile with a range of about 250 miles, also was introduced in 1961, and the liquid-fuel, rocket-powered Mach-1.5 AS-5 Kelt was first deployed in 1966. The Mach-3 AS-6 Kingfish, introduced in 1970, could travel 250 miles.

Ship-based Soviet systems included the SS-N-2 Styx, a subsonic aerodynamic missile first deployed in 1959–60 with a range of 25 miles, and the SS-N-3 Shaddock, a much larger system resembling a swept-wing fighter aircraft with a range of 280 miles. The SS-N-12 Sandbox, introduced in the 1970s on the Kiev-class antisubmarine carriers, was apparently an improved Shaddock. The SS-N-19 Shipwreck, a small, vertically launched, flip-out wing supersonic missile with a range of about 390 miles, appeared in the 1980s.

To defend against antiship missiles, navies employed towed or helicopter-borne decoys. Sometimes chaff (strips of foil or clusters of fine glass or wire) would be released in the air to create false radar targets. Defenses included long-range chaff rockets to mask a vessel from the radar of distant ships, close-in quick-blooming chaff flares to confuse active radar homers on missiles, and radar jamming to defeat acquisition and tracking radars and confuse missile seeker systems. For close-in defense, combatant ships were fitted with high-performance, short-range missiles such as the British Seawolf and automatic gun systems such as the U.S. 20-millimetre Phalanx. Advances in missile-defense systems had to keep up with the natural affinity of antiship missiles for stealth technology: the visual and infrared signatures and radar cross sections of Western antiship missiles became so small that relatively minor modifications in shape and modest applications of radar-absorptive materials could make them difficult to detect with radar and electro-optical systems, except at short ranges.

Antimissile defense

Surface-to-air. Guided surface-to-air missiles, or SAMs, were under development when World War II ended, notably by the Germans, but were not sufficiently perfected to be used in combat. This changed in the 1950s and '60s with the rapid development of sophisticated SAM systems

in the Soviet Union, the United States, Great Britain, and France. With other industrialized nations following suit, surface-to-air missiles of indigenous design, particularly in the smaller categories, were fielded by many armies and navies.

The Soviet Union committed more technical and fiscal resources to the development of guided-missile air-defense systems than any other nation. Beginning with the SA-1 Guild, developed in the immediate postwar period, the Soviets steadily fielded SAMs of growing sophistication. These fell into two categories: systems such as the Guild, the SA-3 Goa, the SA-5 Gammon, and the SA-10 Grumble, which were deployed in defense of fixed installations; and mobile tactical systems capable of accompanying land forces. Most of the tactical systems had naval versions. The SA-2 Guideline, introduced in 1958, was the most widely deployed of the early SAMs and was the first surface-to-air guided-missile system used in combat. This two-stage missile with a solid booster and a liquid-propellant (kerosene and nitric acid) sustainer, could engage targets at ranges of 28 miles and as high as 60,000 feet. Equipped with an array of van-mounted radars for target acquisition and tracking and for missile tracking and command guidance, Guideline proved effective in Vietnam. With adequate warning, U.S. fighters could outmaneuver the relatively large missiles, called "flying telephone poles" by pilots, and electronic countermeasures (ECM) reduced the effectiveness of the tracking radars; but, while these SAMs inflicted relatively few losses, they forced U.S. aircraft down to low altitudes, where antiaircraft artillery and small arms exacted a heavy toll. Later versions of the SA-2 were equipped with optical tracking to counter the effects of ECM; this became a standard feature on SAM systems. After retirement from first-line Soviet service, the SA-2 remained in use in the Third World.

The SA-3 Goa, derived from the Guideline but modified for use against low-altitude targets, was first deployed in 1963—primarily in defense of fixed installations. The SA-N-1 was a similar naval missile.

The SA-4 Ganef was a long-range mobile system first deployed in the mid-1960s; the missiles, carried in pairs on a tracked launcher, used drop-off solid-fuel boosters and a ramjet sustainer motor. Employing a combination of radar command guidance and active radar homing, and supported by an array of mobile radars for target acquisition, tracking, and guidance, they could engage targets over the horizon. (Because the SA-4 strongly resembled the earlier British Bloodhound, NATO assigned it the code name Ganef, meaning "Thief" in Hebrew.) Beginning in the late 1980s, the SA-4 was replaced by the SA-12 Gladiator, a more compact and capable system.

The SA-5 Gammon was a high- and medium-altitude strategic missile system with a range of 185 miles; it was exported to Syria and Libya. The SA-6 Gainful was a mobile tactical system with a range of two to 35 miles and a ceiling of 50,000 feet. Three 19-foot missiles were carried in canisters atop a tracked transporter-erector-launcher, or TEL (see Figure 18), and the radar and fire-control systems were mounted on a similar vehicle, each of which supported four TELs. The missiles used semiactive radar homing and were powered by a combination of solid-rocket and ramjet propulsion. (The SA-N-3 Goblet was a similar naval system.) Gainful, the first truly mobile land-based SAM system, was first used in combat during the 1973 Arab-Israeli War and was highly effective at first against Israeli fighters. The Mach-3 missile proved virtually impossible to outmaneuver, forcing the fighters to descend below effective radar coverage, where antiaircraft guns such as the ZSU 23-4 mobile system were particularly lethal. (Similar factors prevailed in the 1982 Falklands conflict, where long-range British Sea Dart missiles achieved relatively few kills but forced Argentine aircraft down to wave-top level.) The SA-6 was replaced by the SA-11 Gadfly beginning in the 1980s.

The SA-8 Gecko, first deployed in the mid-1970s, was a fully mobile system mounted on a novel six-wheeled amphibious vehicle. Each vehicle carried four canister-launched, semiactive radar homing missiles, with a range of about 7.5 miles, plus guidance and tracking equipment

in a rotating turret. It had excellent performance but, in Syrian hands during the 1982 conflict in Lebanon, proved vulnerable to Israeli electronic countermeasures. The equivalent naval system was the widely deployed SA-N-4 Goblet.

The SA-7 Grail shoulder-fired, infrared-homing missile was first deployed outside the Soviet Union in the final stages of the Vietnam War; it also saw extensive action in the Middle East. The SA-9 Gaskin carried four infrared-homing missiles on a turreted mount atop a four-wheeled vehicle. Its missiles were larger than the SA-7 and had more sophisticated seeker and guidance systems.

The first generation of American SAMs included the Army Nike Ajax, a two-stage, liquid-fueled missile that became operational in 1953, and the rocket-boosted, ramjet-powered Navy Talos. Both used radar tracking and target acquisition and radio command guidance. The later Nike Hercules, also command-guided, had a range of 85 miles. After 1956 the Talos was supplemented by the Terrier, a radar-beam rider, and the Tartar, a semiactive radar homing missile. These were replaced in the late 1960s by the Standard semiactive radar homing system. The solid-fueled, Mach-2 Standard missiles were deployed in medium-range (MR) and two-stage extended-range (ER) versions capable, respectively, of about 15 miles and 35 miles. Within 10 years a second generation of Standard missiles doubled the range of both versions. These newer missiles contained an inertial-guidance system that, by electronically communicating with the Aegis radar fire-control system, allowed corrections to be made in midcourse before the semiactive terminal homing took over (see Figure 32).

For 20 years, the most important land-based American SAM was the Hawk, a sophisticated system employing semiactive radar guidance. From the mid-1960s the Hawk provided the backbone of U.S. surface-based air defenses in Europe and South Korea and was exported to many allies. In Israeli use, Hawk missiles proved highly effective against low-flying aircraft. The longer-ranged Patriot missile system began entering service in 1985 as a partial replacement for the Hawk. Like the Hawk, the Patriot was semimobile; that is, the system components were not mounted permanently on vehicles and so had to be removed from their transport for firing. For target acquisition and identification, as well as for tracking and guidance, the Patriot system used a single phased-array radar, which controlled the direction of the beam by electronically varying the signals at several antennas rather than pivoting a single large antenna. The single-stage, solid-fueled Patriot missile was controlled by command guidance and employed track-via-missile homing, in which information from the radar in the missile itself was used by the launch site fire-control system.

The shoulder-fired Redeye, an infrared-homing missile that was also deployed on truck-mounted launchers, was fielded in the 1960s to provide U.S. Army units close-in protection against air attack. After 1980 the Redeye was replaced by the Stinger (see Figure 18), a lighter system whose missile accelerated faster and whose more advanced seeker head could detect the hot exhaust of approaching aircraft even four miles away and up to 5,000 feet in altitude.

Western European mobile SAM systems include the German-designed Roland, an SA-8 equivalent fired from a variety of tracked and wheeled vehicles, and the French Crotale, an SA-6 equivalent that used a combination of radar command guidance and infrared terminal homing. Both systems were widely exported. Less directly comparable to Soviet systems was the British Rapier, a short-range, semimobile system intended primarily for airfield defense. The Rapier missile was fired from a small, rotating launcher that was transported by trailer. In the initial version, deployed in the early 1970s and used with some success in 1982 in the Falklands conflict (see Figure 18), the target aircraft was tracked by a gunner using an optical sight. A television camera in the tracker measured differences between the missile's flight path and the path to the target, and microwave radio signals issued guidance corrections. The Rapier had a combat range of one-

The SA-6 Gainful (margin note)

The Standard (margin note)

The Rapier (margin note)

quarter to four miles and a ceiling of 10,000 feet. Later versions used radar tracking and guidance for all-weather engagements.

A new generation of Soviet SAM systems entered service in the 1980s. These included the SA-10 Grumble, a Mach-6 mobile system with a 60-mile range deployed in both strategic and tactical versions; the SA-11 Gadfly, a Mach-3 semiactive radar homing system with a range of 17 miles; the SA-12 Gladiator, a track-mobile replacement of Ganef; the SA-13 Gopher, a replacement for Gaskin; and the SA-14, a shoulder-fired Grail replacement. Both Grumble and Gadfly had naval equivalents, the SA-N-6 and SA-N-7. The Gladiator might have been designed with an antimissile capability, making it an element of the antiballistic missile defense around Moscow.   (J.F.G.)

STRATEGIC MISSILES

Strategic missiles represent a logical step in the attempt to attack enemy forces at a distance. As such, they can be seen as extensions of either artillery (in the case of ballistic missiles) or manned aircraft (in the case of cruise missiles). Ballistic missiles are rocket-propelled weapons that travel by momentum in a high, arcing trajectory after they have been launched into flight by a brief burst of power. Cruise missiles, on the other hand, are powered continuously by air-breathing jet engines and are sustained along a low, level flight path by aerodynamic lift.

Although experiments were undertaken before World War II on crude prototypes of the cruise and ballistic missiles, the modern weapons are generally considered to have their true origins in the V-1 and V-2 missiles launched by Germany in 1944–45. Both of those Vergeltungswaffen, or "Vengeance Weapons," defined the problems of propulsion and guidance that have continued ever since to shape cruise and ballistic missile development.

Long-range missiles and nuclear warheads

Given the extremely long ranges required of strategic weapons, even the most modern guidance systems cannot deliver a missile's warhead to the target with consistent, pinpoint accuracy. For this reason, strategic missiles have almost exclusively carried nuclear warheads, which need not strike a target directly in order to destroy it. By contrast, missiles of shorter range (often called tactical- or battlefield-range) have been fitted with both nuclear and conventional warheads. For example, the SS-1 Scud, a ballistic missile with ranges of up to 185 miles (300 kilometres), was fielded with nuclear warheads by Soviet troops in eastern Europe from the 1950s through the 1980s; but in the "war of the cities" during the Iran–Iraq conflict of the 1980s, many SS-1s armed with conventional warheads were launched by both sides, killing thousands of civilians. Other "dual-capable" short-range ballistic missiles are the U.S. Lance, with a range of about 80 miles, and the Soviet SS-21 Scarab, with a range of 75 miles. (In this section, missile systems of the former Soviet Union are referred to by their NATO designations.)

The exclusively nuclear capacity of strategic-range weapons confined serious development of cruise and ballistic missile technology to the world's nuclear powers—particularly the United States and the former Soviet Union. These two countries took different paths in exploiting missile technology. Soviet cruise missiles, for instance, were designed mostly for tactical antiship use rather than for threatening strategic land targets (as was the U.S. emphasis). Throughout the ballistic missile arms race, the United States tended to streamline its weapons, seeking greater accuracy and lower explosive power, or yield. Meanwhile, the Soviet Union, perhaps to make up for its difficulties in solving guidance problems, concentrated on larger missiles and higher yields. Most U.S. systems carried warheads of less than one megaton, with the largest being the nine-megaton Titan II, in service from 1963 through 1987. The Soviet warheads often exceeded five megatons, with the largest being a 20- to 25-megaton warhead deployed on the SS-7 Saddler from 1961 to 1980 and a 25-megaton warhead on the SS-9 Scarp, deployed from 1967 to 1982. (For the development of nuclear weapons, see below *Nuclear weapons*.)

Most other countries pursuing missile technology have not developed strategic weapons to the extent of the United States and the former Soviet Union. Nonetheless, several other nations have produced them; their emphasis, however, has been on ballistic rather than cruise missiles because of the extremely sophisticated guidance systems required of cruise missiles. Also, as with any technology, there has occurred a transfer of ballistic missile technology to less-developed countries. Combined with the widespread capacity to produce chemical warheads, such weapons represent a potent addition to the arsenals of emerging powers of the Third World.

Ballistic missiles. Strategic ballistic missiles can be divided into two general categories according to their basing mode: those that are launched from land and those launched at sea (from submarines beneath the surface). They also can be divided according to their range into intermediate-range ballistic missiles (IRBMs) and intercontinental ballistic missiles (ICBMs). IRBMs have ranges of about 600 to 3,500 miles, while ICBMs have ranges exceeding 3,500 miles. Modern land-based strategic missiles are almost all of ICBM range, whereas all but the most modern submarine-launched ballistic missiles (SLBMs) have been of intermediate range.

IRBMs and ICBMs

Prelaunch survivability (that is, the ability to survive an enemy attack) has been a long-standing problem with land-based ICBMs. (SLBMs achieve survivability by being based on relatively undetectable submarines.) At first, they were considered safe from attack because neither U.S. nor Soviet missiles were sufficiently accurate to strike the other's launch sites; hence, early systems were launched from above ground. However, as missile accuracies improved, above-ground missiles became vulnerable, and in the 1960s both countries began to base their ICBMs below ground in concrete tubes called silos, some of which were hardened against nuclear blast. Later, even greater improvements in accuracy brought ICBM basing strategy back to above-ground systems. This time, prelaunch survivability was to be achieved by mobile ICBMs that would confound an attacker with multiple moving targets.

Most U.S. silos are designed for one-time "hot-launch" use, the rocket engines igniting within the silo and essentially destroying it as the missile departs. The Soviets pioneered the "cold-launch" method, in which the missile is expelled by gas and the rocket engine ignited after the missile clears the silo. This method, essentially the same system used with SLBMs, allows silos to be reused after minor repair.

In order to increase their range and throw weight, ballistic missiles are usually multistaged. By shedding weight as the flight progresses (that is, by burning the fuel and then discarding the pumps, flight controls, and associated equipment of the previous stage), each successive stage has less mass to accelerate. This permits a missile to fly farther and carry a larger payload.

The flight path of a ballistic missile has three successive phases. In the first, called the boost phase, the rocket engine (or engines, if the missile contains two or three stages) provides the precise amount of propulsion required to place the missile on a specific ballistic trajectory. Then the engine quits, and the final stage of the missile (called the payload) coasts in the midcourse phase, usually beyond the Earth's atmosphere. The payload contains the warhead (or warheads), the guidance system, and such penetration aids as decoys, electronic jammers, and chaff to help elude enemy defenses. The weight of this payload constitutes the missile's throw weight—that is, the total weight that the missile is capable of placing on a ballistic trajectory toward a target. By midcourse the warheads have detached from the remainder of the payload, and all elements are on a ballistic path. The terminal phase of flight occurs when gravity pulls the warheads (now referred to as the reentry vehicles, or RVs) back into the atmosphere and down to the target area.

Boost, midcourse, and reentry phases

Most ballistic missiles use inertial guidance to arrive at the vicinity of their targets. This technology, based on Newtonian physics, involves measuring disturbances to the missile in three axes. The device used to measure these disturbances is usually composed of three gyroscopically stabilized accelerometers mounted at right angles to one another. By calculating the acceleration imparted by ex-
Figure 19: *Flight path of an intercontinental ballistic missile (ICBM).*
While being boosted into a ballistic trajectory beyond the Earth's atmosphere, the missile's final stage, called the bus, would dispense its nuclear warheads, or reentry vehicles. Decoys and a cloud of reflective chaff would confuse the enemy's radar-guided defenses, and the reentry vehicles would strike their targets within 30 minutes of launch. By that time, retaliatory ICBMs would probably be on their way.

From L. Freedman, *Atlas of Global Strategy,* copyright © Equinox (Oxford) Ltd 1985

ternal forces (including the rocket engine's thrust), and by comparing these forces to the launch position, the guidance system can determine the missile's position, velocity, and heading. Then the guidance computer, predicting the gravitational forces that will act on the reentry vehicle, can calculate the velocity and heading required to reach a predetermined point on the ground. Given these calculations, the guidance system can issue a command to the missile thrust system during boost phase to place the payload at a specific point in space, on a specific heading, and at a specific velocity—at which point thrust is shut off and a purely ballistic flight path begins.

Ballistic missile guidance is complicated by two factors. First, during the latter stages of the powered boost phase, the atmosphere is so thin that aerodynamic flight controls such as fins cannot work and the only corrections that can be made to the flight path must come from the rocket engines themselves. But, because the engines only provide a force vector roughly parallel to the missile's fuselage, they cannot be used to provide major course corrections; making major corrections would create large gravitational forces perpendicular to the fuselage that could destroy the missile. Nevertheless, small corrections can be made by slightly gimballing the main engines so that they swivel, by placing deflective surfaces called vanes within the rocket exhaust, or, in some instances, by fitting small rocket engines known as thrust-vector motors or thrusters. This technique of introducing small corrections into a missile's flight path by slightly altering the force vector of its engines is known as thrust-vector control.

A second complication occurs during reentry to the atmosphere, when the unpowered RV is subject to relatively unpredictable forces such as wind. Guidance systems have had to be designed to accommodate these difficulties.

Errors in accuracy for ballistic missiles (and for cruise missiles as well) are generally expressed as launch-point errors, guidance/en-route errors, or aim-point errors. Both launch- and aim-point errors can be corrected by surveying

the launch and target areas more accurately. Guidance/ en-route errors, on the other hand, must be corrected by improving the missile's design—particularly its guidance. Guidance/en-route errors are usually measured by a missile's circular error of probability (CEP) and bias. CEP uses the mean point of impact of missile test firings, usually taken at maximum range, to calculate the radius of a circle that would take in 50 percent of the impact points. Bias measures the deviation of the mean impact point from the actual aim point. An accurate missile has both a low CEP and low bias.

The V-2. The precursor of modern ballistic missiles was the German V-2, a single-stage, fin-stabilized missile propelled by liquid oxygen and ethyl alcohol to a maximum range of about 200 miles (see Figure 20). The V-2 was officially designated the A-4, being derived from the fourth of the *Aggregat* series of experiments conducted at Kummersdorf and Peenemunde under General Walter Dornberger and the civilian scientist Wernher von Braun.

The most difficult technical problem facing the V-2 was achieving maximum range. An inclined launch ramp was normally used to give missiles maximum range, but this could not be used with the V-2 because the missile was quite heavy at lift-off (more than 12 tons) and would not be traveling fast enough to sustain anything approaching horizontal flight. Also, as the rocket used up its fuel its weight (and velocity) would change, and this had to be allowed for in the aiming. For these reasons the V-2 had to be launched straight up and then had to change to the flight angle that would give it maximum range. The Germans calculated this angle to be slightly less than 50°.

The change in direction mandated some sort of pitch control during flight, and, because a change in pitch would induce yaw, control was needed on the yaw axis too. Added to these problems was the natural tendency of a cylinder to rotate. Thus, the V-2 (and every ballistic missile afterward) needed a guidance and control system to deal with in-flight rolling, pitching, and yawing. Using

Thrust-vector control

Early problems in flight control

Bilderdienst im Süddeutschen Verlag

three-axis autopilots adapted from German aircraft, the V-2 was controlled by large vertical fins and smaller stabilizing surfaces to dampen roll and by vanes attached to the horizontal fins to modify pitch and yaw. Vanes were also installed in the exhaust nozzle for thrust vector control.

A combination of in-flight weight changes and changes in atmospheric conditions presented additional problems. Even over the fairly limited course of a V-2 trajectory (with a range of approximately 200 miles and an altitude of roughly 50 miles), changes in missile velocity and air density produced drastic shifts in the distance between the centre of gravity and the centre of aerodynamic pressure. This meant the guidance system had to adjust its input to the control surfaces as the flight proceeded. As a result, V-2 accuracy never ceased to be a problem for the Germans.

Still, the missile caused a great deal of damage. The first V-2 used in combat was fired against Paris on Sept. 6, 1944. Two days later the first of more than 1,000 missiles was fired against London. By the end of the war 4,000 of these missiles had been launched from mobile bases against Allied targets. During February and March 1945, only weeks before the war in Europe ended, an average of 60 missiles was launched weekly. The V-2 killed an estimated five persons per launch (versus slightly more than two per launch for the V-1). Three major factors contributed to this difference. First, the V-2 warhead weighed more than 1,600 pounds (725 kilograms). Second, several V-2 attacks killed more than 100 people. Finally, there was no known defense against the V-2; it could not be intercepted and, traveling faster than sound, it arrived unexpectedly. The V-2 threat was eliminated only by bombing the launch sites and forcing the German army to retreat beyond missile range.

The V-2 obviously ushered in a new age of military technology. After the war there was intense competition between the United States and the Soviet Union to obtain these new missiles, as well as to obtain the German scientists who had developed them. The United States succeeded in capturing both Dornberger and von Braun as well as more than 60 V-2s; it was not revealed precisely what (or whom) the Soviets captured. However, given the relative immaturity of ballistic missile technology at that time, neither country achieved usable ballistic missiles for some time. During the late 1940s and early 1950s most of the nuclear competition between the two countries dealt with strategic bombers. Events in 1957 reshaped this contest.

The first ICBMs. In 1957 the Soviets launched a multistage ballistic missile (later given the NATO designation SS-6 Sapwood) as well as the first man-made satellite, Sputnik. This prompted the "missile gap" debate in the United States and resulted in higher priorities for the U.S. Thor and Jupiter IRBMs. Although originally scheduled for deployment in the early 1960s, these programs were

Thor and
Jupiter

accelerated, with Thor being deployed to England and Jupiter to Italy and Turkey in 1958. Thor and Jupiter were both single-stage, liquid-fueled missiles with inertial guidance systems and warheads of 1.5 megatons. Political difficulties in deploying these missiles on foreign soil prompted the United States to develop ICBMs, so that by late 1963 Thor and Jupiter had been terminated. (The missiles themselves were used extensively in the space program.)

The Soviet SS-6 system was an apparent failure. Given its limited range (less than 3,500 miles), it had to be launched from northern latitudes in order to reach the United States. The severe weather conditions at these launch facilities (Novaya Zemlya and the Arctic mainland bases of Norilsk and Vorkuta) seriously degraded operational effectiveness; pumps for liquid propellants froze, metal fatigue was extreme, and lubrication of moving parts was nearly impossible. In 1960 a missile engine exploded during a test, killing Mitrofan Ivanovich Nedelin, chief of the Strategic Rocket Forces, and several hundred observers.

Possibly as a result of these technical failures (and possibly in response to the deployment of Thor and Jupiter), the Soviets attempted to base the SS-4 Sandal, an IRBM with a one-megaton warhead and a range of 900–1,000 miles, closer to the United States and in a warmer climate. This precipitated the Cuban missile crisis of 1962, after which the SS-4 was withdrawn to Central Asia. (It was unclear whether the United States' deactivation of Thor and Jupiter was a condition of this withdrawal.)

In the meantime, the United States was developing operational ICBMs to be based on U.S. territory. The first versions were the Atlas and the Titan I. The Atlas-D (the first version deployed) had a liquid-fueled engine that generated 360,000 pounds of thrust. The missile was radio-inertial guided, launched above ground, and had a range of 7,500 miles. The follow-on Atlas-E/F increased thrust to 390,000 pounds, used all-inertial guidance, and moved from an aboveground to horizontal canister launch in the E and, finally, to silo-stored vertical launch in the F. The Atlas E carried a two-megaton, and the Atlas F a four-megaton, warhead. The Titan I was a two-stage, liquid-fueled, radio-inertial guided, silo-launched ICBM carrying a four-megaton warhead and capable of traveling 6,300 miles. Both systems became operational in 1959.

From liquid to solid fuel. This first generation of missiles was typified by its liquid fuel, which required both a propellant and an oxidizer for ignition as well as a complex (and heavy) system of pumps. The early liquid fuels were quite dangerous, difficult to store, and time-consuming to load. For example, Atlas and Titan used so-called cryogenic (hypercold) fuels that had to be stored and handled at very low temperatures (−422° F [−252° C] for liquid hydrogen). These propellants had to be stored outside the rocket and pumped aboard just before launch, consuming more than an hour.

As each superpower produced, or was thought to produce, more ICBMs, military commanders became concerned about the relatively slow reaction times of their own ICBMs. The first step toward "rapid reaction" was the rapid loading of liquid fuels. Using improved pumps, the reaction time of the Titan I was reduced from over one hour to less than 20 minutes. Then, with a second generation of storable liquids that could be kept loaded in the missile, reaction time was reduced to approximately one minute. Examples of second-generation storable-liquid missiles were the Soviet SS-7 Saddler and SS-8 Sasin (the latter deployed in 1963) and the U.S. Titan II. The Titan II was the largest ballistic missile ever developed by the United States. This two-stage ICBM was more than 100 feet long and 10 feet in diameter. Weighing more than 325,000 pounds at launch, it delivered its single warhead (with a throw weight of about 8,000 pounds) to a range of 9,000 miles and with a CEP of about one mile.

Storable
liquids

In about 1964 China began developing a series of liquid-fueled IRBMs given the NATO designation CSS, for Chinese surface-to-surface missile. (The Chinese named the series Dong Feng, meaning "East Wind.") The CSS-1 carried a 20-kiloton warhead to a range of 600 miles. The CSS-2, entering service in 1970, was fueled by storable

liquids; it had a range of 1,500 miles and carried a one- to two-megaton warhead. With the two-stage CSS-3 (active from 1978) and the CSS-4 (active from 1980), the Chinese reached ICBM ranges of over 4,000 and 7,000 miles, respectively. The CSS-4 carried a warhead of four to five megatons.

Because storable liquids did not alleviate the dangers inherent in liquid fuels, and because the flight times of missiles flying between the United States and the Soviet Union shrank to less than 35 minutes from launch to impact, still faster reactions were sought with even safer fuels. This led to a third generation of missiles, powered by solid propellants. Solid propellants were, eventually, easier to make, safer to store, lighter in weight (because they did not require on-board pumps), and more reliable than their liquid predecessors. Here the oxidizer and propellant were mixed into a canister and kept loaded aboard the missile, so that reaction times were reduced to seconds. However, solid fuels were not without their complications. First, while it was possible with liquid fuels to adjust in flight the amount of thrust provided by the engine, rocket engines using solid fuel could not be throttled. Also, some early solid fuels had uneven ignition, producing surges or abrupt velocity changes that could disrupt or severely confound guidance systems.

The first solid-fueled U.S. system was the Minuteman I. This ICBM, conceived originally as a rail-mobile system, was deployed in silos in 1962, became operational the following year, and was phased out by 1973. The first Soviet solid-fueled ICBM was the SS-13 Savage, which became operational in 1969. This missile could carry a 750-kiloton warhead more than 5,000 miles. Because the Soviet Union deployed several other liquid-fueled ICBMs between 1962 and 1969, Western specialists speculated that the Soviets experienced engineering difficulties in producing solid propellants.

The French deployed the first of their solid-fueled S-2 missiles in 1971. These two-stage IRBMs carried a 150-kiloton warhead and had a range of 1,800 miles. The S-3, deployed in 1980, could carry a one-megaton warhead to a range of 2,100 miles.

The first SLBMs. Simultaneous with the early Soviet and U.S. efforts to produce land-based ICBMs, both countries were developing SLBMs. In 1955 the Soviets launched the first SLBM, the one- to two-megaton SS-N-4 Sark. This missile, deployed in 1958 aboard diesel-electric submarines and later aboard nuclear-powered vessels, had to be launched from the surface and had a range of only 350 miles. Partly in response to this deployment, the United States gave priority to its Polaris program, which became operational in 1960. Each Polaris A-1 carried a warhead of one megaton and had a range of 1,400 miles. The Polaris A-2, deployed in 1962, had a range of 1,700 miles and also carried a one-megaton warhead. The U.S. systems were solid-fueled, whereas the Soviets initially used storable liquids. The first Soviet solid-fueled SLBM was the SS-N-17 Snipe, deployed in 1978 with a range of 2,400 miles and a 500-kiloton warhead.

Beginning in 1971, France deployed a series of solid-fueled SLBMs comprising the M-1, M-2 (1974), and M-20 (1977). The M-20, with a range of 1,800 miles, carried a one-megaton warhead. In the 1980s the Chinese fielded the two-stage, solid-fueled CSS-N-3 SLBM, which had a range of 1,700 miles and carried a two-megaton warhead.

Multiple warheads. By the early 1970s, several technologies were maturing that would produce a new wave of ICBMs. First, thermonuclear warheads, much lighter than the earlier atomic devices, had been incorporated into ICBMs by 1970. Second, the ability to launch larger throw weights, achieved especially by the Soviets, allowed designers to contemplate adding multiple warheads to each ballistic missile. Finally, improved and much lighter electronics translated into more accurate guidance.

The first steps toward incorporating these technologies came with multiple warheads, or multiple reentry vehicles (MRVs), and the Fractional Orbital Bombardment System (FOBS). The Soviets introduced both of these capabilities with the SS-9 Scarp, the first "heavy" missile, beginning in 1967. FOBS was based on a low-trajectory launch that

would be fired in the opposite direction from the target and would achieve only partial earth orbit. With this method of delivery, it would be quite difficult to determine which target was being threatened. However, given the shallow reentry angles associated with a low trajectory and partial earth orbit, the accuracy of FOBS missiles was questionable. A missile carrying MRVs, on the other hand, would be launched toward the target in a high ballistic trajectory. Several warheads from the same missile would strike the same target, increasing the probability of killing that target, or individual warheads would strike separate targets within a very narrow ballistic "footprint." (The footprint of a missile is that area which is feasible for targeting, given the characteristics of the reentry vehicle.) The SS-9, model 4, and the SS-11 Sego, model 3, both had three MRVs and ballistic footprints equal to the dimensions of a U.S. Minuteman complex. The only instance in which the United States incorporated MRVs was with the Polaris A-3, which, after deployment in 1964, carried three 200-kiloton warheads a distance of 2,800 miles. In 1967 the British adapted their own warheads to the A-3, and beginning in 1982 they upgraded the system to the A3TK, which contained penetration aids (chaff, decoys, and jammers) designed to foil ballistic missile defenses around Moscow.

Soon after adopting MRVs the United States took the next technological step, introducing multiple independently targetable reentry vehicles (MIRVs). Unlike MRVs, independently targeted RVs could be released to strike widely separated targets, essentially expanding the footprint established by a missile's original ballistic trajectory. This demanded the capacity to maneuver before releasing the warheads, and maneuvering was provided by a structure in the front end of the missile called the "bus," which contained the RVs. The bus was essentially a final, guided stage of the missile (usually the fourth), that now had to be considered part of the missile's payload. Since any bus capable of maneuvering would take up weight, MIRVed systems would have to carry warheads of lower yield. This in turn meant that the RVs would have to be released on their ballistic paths with great accuracy. As stated above, solid-fueled motors could be neither throttled nor shut down and restarted; for this reason, liquid-fueled buses were developed for making the necessary course corrections. The typical flight profile for a MIRVed ICBM then became approximately 300 seconds of solid-rocket boost and 200 seconds of bus maneuvering to place the warheads on independent ballistic trajectories.

The first MIRVed system was the U.S. Minuteman III. Deployed in 1970, this three-stage, solid-fueled ICBM carried three MIRVs of an estimated 170 to 335 kilotons. The warheads had a range of 8,000 miles with CEPs of 725–925 feet. Beginning in 1970 the United States also MIRVed its SLBM force with the Poseidon C-3, which could deliver up to 14 50-kiloton RVs to a range of 2,800 miles and with a CEP of about 1,450 feet. After 1979 this force was upgraded with the Trident C-4, or Trident I, which could deliver eight 100-kiloton MIRVs with the same accuracy as the Poseidon, but to a distance of 4,600 miles. Much longer range was made possible in the Trident by adding a third stage, by replacing aluminum with lighter graphite epoxies, and by adding an "aerospike" to the nose cone that, extending after launch, produced the streamlining effect of a pointed design while allowing the larger volume of a blunt design. Accuracy was maintained by updating the missile's inertial guidance during bus maneuvering with stellar navigation.

By 1978 the Soviet Union had fielded its first MIRVed SLBM, the SS-N-18 Stingray. This liquid-fueled missile could deliver three or five 500-kiloton warheads to a distance of 4,000 miles, with a CEP of about 3,000 feet. On land in the mid-1970s, the Soviets deployed three MIRVed, liquid-fueled ICBM systems, all with ranges exceeding 6,000 miles and with CEPs of 1,000 to 1,500 feet: the SS-17 Spanker, with four 750-kiloton warheads; the SS-18 Satan, with up to 10 500-kiloton warheads; and the SS-19 Stiletto, with six 550-kiloton warheads. Each of these Soviet systems had several versions that traded multiple warheads for higher yield. For instance, the SS-18,

model 3, carried a single 20-megaton warhead. This giant missile, which replaced the SS-9 in the latter's silos, had about the same dimensions as the Titan II, but its throw weight of more than 16,000 pounds was twice that of the U.S. system.

Beginning in 1985, France upgraded its SLBM force with the M-4, a three-stage MIRVed missile capable of carrying six 150-kiloton warheads to ranges of 3,600 miles.

MX Peace-keeper
A second generation of MIRVed U.S. systems was represented by the Peacekeeper. Known as the MX during its 15-year development phase before entering service in 1986, this three-stage ICBM carried 10 300-kiloton warheads and had a range of 7,000 miles. Originally designed to be based on mobile railroad or wheeled launchers, the Peacekeeper was eventually housed in Minuteman silos. A second-generation MIRVed SLBM of the 1990s was the Trident D-5, or Trident II. Even though it was one-third again as long as its predecessor and had twice the throw weight, the D-5 could deliver 10 475-kiloton warheads to a range of 7,000 miles. Both the Trident D-5 and Peacekeeper represented a radical advance in accuracy, having CEPs of only 400 feet. The improved accuracy of the Peacekeeper was due to a refinement in the inertial guidance system, which housed the gyros and accelerometers in a floating-ball device, and to the use of an exterior celestial navigation system that updated the missile's position by reference to stars or satellites. The Trident D-5 also contained a star sensor and satellite navigator. This gave it several times the accuracy of the C-4 at more than twice the range.

Within the generally less-advanced guidance technology of the Soviet Union, an equally radical advance came with the solid-fueled SS-24 Scalpel and SS-25 Sickle ICBMs, deployed in 1987 and 1985, respectively. The SS-24 could carry eight or 10 MIRVed warheads of 100 kilotons, and the SS-25 was fitted with a single 550-kiloton RV. Both missiles had a CEP of 650 feet. In addition to their accuracy, these ICBMs represented a new generation in basing mode. The SS-24 was launched from railroad cars, while the SS-25 was carried on wheeled launchers that shuttled between concealed launch sites. As mobile-based systems, they were long-range descendants of the SS-20 Saber, an IRBM carried on mobile launchers that entered service in 1977, partly along the border with China and partly facing western Europe. That two-stage, solid-fueled missile could deliver three 150-kiloton warheads a distance of 3,000 miles with a CEP of 1,300 feet. It was phased out after the signing of the Intermediate-Range Nuclear Forces (INF) Treaty in 1987.

Ballistic missile defense. Although ballistic missiles followed a predictable flight path, defense against them was long thought to be technically impossible because their RVs were small and traveled at great speeds. Nevertheless, in the late 1960s the United States and Soviet Union pursued layered antiballistic missile (ABM) systems that combined a high-altitude interceptor missile (the U.S. Spartan and Soviet Galosh) with a terminal-phase interceptor (the U.S. Sprint and Soviet Gazelle). All systems were nuclear-armed. Such systems were subsequently limited by the Treaty on Anti-Ballistic Missile Systems of 1972, under a protocol in which each side was allowed one ABM location with 100 interceptor missiles each. The Soviet system, around Moscow, remained active and was upgraded in the 1980s, whereas the U.S. system was deactivated in 1976. Still, given the potential for renewed or surreptitious ballistic missile defenses, all countries incorporated penetration aids along with warheads in their missiles' payloads. MIRVs also were used to overcome missile defenses.

Maneuverable warheads. Even after a missile's guidance has been updated with stellar or satellite references, disturbances in final descent could throw a warhead off course. Also, given the advances in ballistic missile defenses that were achieved even after the ABM treaty was signed, RVs remained vulnerable. Two technologies offered possible means of overcoming these difficulties. Maneuvering warheads, or MaRVs, were first integrated into the U.S. Pershing II IRBMs deployed in Europe from 1984 until they were dismantled under the terms of the

INF Treaty. The warhead of the Pershing II contained a radar area guidance (Radag) system that compared the terrain toward which it descended with information stored in a self-contained computer. The Radag system then issued commands to control fins that adjusted the glide of the warhead. Such terminal-phase corrections gave the Pershing II, with a range of 1,100 miles, a CEP of 150 feet. The improved accuracy allowed the missile to carry a low-yield 15-kiloton warhead.

Pershing II and Radag guidance

MaRVs would present ABM systems with a shifting, rather than ballistic, path, making interception quite difficult. Another technology, precision-guided warheads, or PGRVs, would actively seek a target, then, using flight controls, actually "fly out" reentry errors. This could yield such accuracy that nuclear warheads could be replaced by conventional explosives.

Cruise missiles. The single most important difference between ballistic missiles and cruise missiles is that the latter operate within the atmosphere. This presents both advantages and disadvantages. One advantage of atmospheric flight is that traditional methods of flight control (*e.g.*, airfoil wings for aerodynamic lift, rudder and elevator flaps for directional and vertical control) are readily available from the technologies of manned aircraft. Also, while strategic early-warning systems can immediately detect the launch of ballistic missiles, low-flying cruise missiles presenting small radar and infrared cross sections offer a means of slipping past these air-defense screens.

The principal disadvantage of atmospheric flight centres around the fuel requirements of a missile that must be powered continuously for strategic distances. Some tactical-range antiship cruise missiles such as the U.S. Harpoon have been powered by turbojet engines, and even some non-cruise missiles such as the Soviet SA-6 Gainful surface-to-air missile employed ramjets to reach supersonic speed, but at ranges of 1,000 miles or more these engines would require enormous amounts of fuel. This in turn would necessitate a larger missile, which would approach a manned jet aircraft in size and would thereby lose the unique ability to evade enemy defenses. This problem of maintaining balance between range, size, and fuel consumption was not solved until reliable, fuel-efficient turbofan engines were made small enough to propel a missile of radar-evading size.

As with ballistic missiles, guidance has been a long-standing problem in cruise missile development. Tactical cruise missiles generally use radio or inertial guidance to reach the general vicinity of their targets and then home onto the targets with various radar or infrared mechanisms. Radio guidance, however, is subject to line-of-sight range limitations, and inaccuracies tend to arise in inertial systems over the long flight times required of strategic cruise missiles. Radar and infrared homing devices, moreover, can be jammed or spoofed. Adequate long-range guidance for cruise missiles was not available until inertial systems were designed that could be updated periodically by self-contained electronic map-matching devices.

The problem of guidance

Beginning in the 1950s, the Soviet Union pioneered the development of tactical air- and sea-launched cruise missiles, and in 1984 a strategic cruise missile given the NATO designation AS-15 Kent became operational aboard Tu-95 bombers. But Soviet programs were so cloaked in secrecy that the following account of the development of cruise missiles focuses by necessity on U.S. programs.

The V-1. The first practical cruise missile was the German V-1 of World War II, which was powered by a pulse jet that used a cycling flutter valve to regulate the air and fuel mixture. Because the pulse jet required airflow for ignition, it could not operate below 150 miles per hour. Therefore, a ground catapult boosted the V-1 to 200 miles per hour, at which time the pulse-jet engine was ignited. Once ignited, it could attain speeds of 400 miles per hour and ranges exceeding 150 miles. Course control was accomplished by a combined air-driven gyroscope and magnetic compass, and altitude was controlled by a simple barometric altimeter; as a consequence, the V-1 was subject to heading, or azimuth, errors resulting from gyro drift, and it had to be operated at fairly high altitudes (usually above 2,000 feet) to compensate for altitude er-

rors caused by differences in atmospheric pressure along the route of flight.

The missile was armed in flight by a small propeller that, after a specified number of turns, activated the warhead at a safe distance from the launch. As the V-1 approached its target, the control vanes were inactivated and a rear-mounted spoiler, or drag device, deployed, pitching the missile nose-down toward the target. This usually interrupted the fuel supply, causing the engine to quit, and the weapon detonated upon impact.

Because of the rather crude method of calculating the impact point by the number of revolutions of a small propeller, the Germans could not use the V-1 as a precision weapon, nor could they determine the actual impact point in order to make course corrections for subsequent flights. In fact, the British publicized inaccurate information on impact points, causing the Germans to adjust their preflight calculations erroneously. As a result, V-1s often fell well short of their intended targets.

Following the war there was considerable interest in cruise missiles. Between 1945 and 1948, the United States began approximately 50 independent cruise missile projects, but lack of funding gradually reduced that number to three by 1948. These three—Snark, Navaho, and Matador—provided the necessary technical groundwork for the first truly successful strategic cruise missiles, which entered service in the 1980s.

Snark. The Snark was an air force program begun in 1945 to produce a subsonic (600-mile-per-hour) cruise missile capable of delivering a 2,000-pound atomic or conventional warhead to a range of 5,000 miles, with a CEP of less than 1.75 miles. Initially, the Snark used a turbojet engine and an inertial navigation system, with a complementary stellar navigation monitor to provide intercontinental range. By 1950, due to the yield requirements of atomic warheads, the design payload had changed to 5,000 pounds, accuracy requirements shrank the CEP to 1,500 feet, and range increased to more than 6,200 miles. These design changes forced the military to cancel the first Snark program in favour of a "Super Snark," or Snark II.

The Snark II incorporated a new jet engine that was later used in the B-52 Stratofortress and KC-135A aerial tanker operated by the Strategic Air Command. Although this engine design was to prove quite reliable in manned aircraft, other problems—in particular, those associated with flight dynamics—continued to plague the missile. The Snark lacked a horizontal tail surface, it used elevons instead of ailerons and elevators for attitude and directional control, and it had an extremely small vertical tail surface. These inadequate control surfaces, and the relatively slow (or sometimes nonexistent) ignition of the jet engine, contributed significantly to the missile's difficulties in flight tests—to a point where the coastal waters off the test site at Cape Canaveral, Fla., were often referred to as "Snark-infested waters." Flight control was not the least of the Snark's problems: unpredictable fuel consumption also resulted in embarrassing moments. One 1956 flight test appeared amazingly successful at the outset, but the engine failed to shut off and the missile was last seen "heading toward the Amazon." (The vehicle was found in 1982 by a Brazilian farmer.)

Considering the less than dramatic successes in the test program, the Snark, as well as other cruise missile programs, probably would have been destined for cancellation had it not been for two developments. First, antiaircraft defenses had improved to a point where bombers could no longer reach their targets with the usual high-altitude flight paths. Second, thermonuclear weapons were beginning to arrive in military inventories, and these lighter, higher-yield devices allowed designers to relax CEP constraints. As a result, an improved Snark was deployed in the late 1950s at two bases in Maine and Florida.

The new missile, however, continued to exhibit the unreliabilities and inaccuracies typical of earlier models. On a series of flight tests, the Snark's CEP was estimated to average 20 miles, with the most accurate flight striking 4.2 miles left and 1,600 feet short. This "successful" flight was the only one to reach the target area at all and was one of only two to go beyond 4,400 miles. Accumulated

test data showed that the Snark had a 33-percent chance of successful launch and a 10-percent chance of achieving the required distance. As a consequence, the two Snark units were deactivated in 1961.

Navaho. The second postwar U.S. cruise missile effort was the Navaho, an intercontinental supersonic design. Unlike earlier efforts, which were extrapolated from V-1 engineering, the Navaho was based on the V-2; the basic V-2 structure was fitted with new control surfaces, and the rocket engine was replaced by a turbojet/ramjet combination. Known by a variety of names, the Navaho emerged into a missile more than 70 feet long, with canard fins (*i.e.,* control surfaces set forward of the wing), a V tail, and a large delta wing. (These flight control designs would eventually make their way onto other supersonic aircraft, such as the experimental XB-70 Valkyrie bomber, several fighter planes, and the supersonic transport.)

With the exception of technologies associated with supersonic lift and control, few other aspects of the Navaho met designers' expectations. Most frustrating were difficulties with the ramjet engine, which was necessary for sustained supersonic flight. For a variety of reasons, including interrupted fuel flow, turbulence in the ramjet cavity, and clogging of the ramjet fire-ring, few of the engines ignited. This led engineers to label the project "Never Go, Navaho"—a name that stuck until the program was cancelled in 1958 after achieving only 1½ hours airborne. No missile was ever deployed.

Technologies explored in the Navaho program, besides those of flight dynamics, were used in other areas. Derivatives of the missile's titanium alloys, which were developed to accommodate surface temperatures at supersonic speed, came to be used on most high-performance aircraft. The rocket booster (which launched the missile until the ramjet ignited) eventually became the Redstone engine, which powered the Mercury manned spacecraft series, and the same basic design was used in the Thor and Atlas ballistic missiles. The guidance system, an inertial autonavigation design, was incorporated into a later cruise missile (Hound Dog) and was used by the nuclear submarine USS *Nautilus* for its under-the-ice passage of the North Pole in 1958.

Matador and other programs. The third postwar U.S. cruise missile effort was the Matador, a ground-launched, subsonic missile designed to carry a 3,000-pound warhead to a range of more than 600 miles. In its early development, Matador's radio-controlled guidance, which was limited essentially to the line of sight between the ground controller and the missile, covered less than the missile's potential range. However, in 1954 an automatic terrain recognition and guidance (Atran) system was added (and the missile system was subsequently designated Mace). Atran, which used radar map-matching for both en-route and terminal guidance, represented a major breakthrough in accuracy, a problem long associated with cruise missiles. The low availability of radar maps, especially of areas in the Soviet Union (the logical target area), limited operational use, however. Nonetheless, operational deployments began in 1954 to Europe and in 1959 to Korea. The missile was phased out in 1962, its most serious problems being associated with guidance.

While the U.S. Air Force was exploring the Snark, Navaho, and Matador programs, the navy was pursuing related technologies. The Regulus, which was closely akin to the Matador (having the same engine and roughly the same configuration), became operational in 1955 as a subsonic missile launched from both submarines and surface vessels, carrying a 3.8-megaton warhead. Decommissioned in 1959, the Regulus did not represent much of an improvement over the V-1.

A follow-on design, Regulus II, was pursued briefly, striving for supersonic speed. However, the navy's preference for the new larger, angle-deck nuclear aircraft carriers and for ballistic missile submarines relegated sea-launched cruise missiles to relative obscurity. Another project, the Triton, was similarly bypassed due to design difficulties and lack of funding. The Triton was to have had a range of 12,000 miles and a payload of 1,500 pounds. Radar map-matching guidance was to have given it a CEP of 1,800 feet.

In the early 1960s the Air Force produced and deployed the Hound Dog cruise missile on B-52 bombers. This supersonic missile was powered by a turbojet engine to a range of 400–450 miles. It used the guidance system of the earlier Navaho. The missile was so large, however, that only two could be carried on the outside of the aircraft. This external carriage allowed B-52 crew members to use the Hound Dog engines for extra thrust on takeoff, but the extra drag associated with the carriage, as well as the additional weight (20,000 pounds), meant a net loss of range for the aircraft. By 1976 the Hound Dog had given way to the short-range attack missile, or SRAM, essentially an internally carried, air-launched ballistic missile.

ALCM, SLCM, and GLCM. By 1972, constraints placed on ballistic missiles by the SALT I treaty prompted U.S. nuclear strategists to think again about using cruise missiles. There was also concern over Soviet advances in antiship cruise missile technology, and in Vietnam remotely piloted vehicles had demonstrated considerable reliability in gathering intelligence information over previously inaccessible, highly defended areas. Improvements in electronics—in particular, microcircuits, solid-state memory, and computer processing—presented inexpensive, lightweight, and highly reliable methods of solving the persistent problems of guidance and control. Perhaps most important, terrain contour mapping, or Tercom, techniques, derived from the earlier Atran, offered excellent en route and terminal-area accuracy.

Tercom used a radar or photographic image from which a digitalized contour map was produced. At selected points in the flight known as Tercom checkpoints, the guidance system would match a radar image of the missile's current position with the programmed digital image, making corrections to the missile's flight path in order to place it on the correct course. Between Tercom checkpoints, the missile would be guided by an advanced inertial system; this would eliminate the need for constant radar emissions, which would make electronic detection extremely difficult. As the flight progressed, the size of the radar map would be reduced, improving accuracy. In practice, Tercom brought the CEP of modern cruise missiles down to less than 150 feet (see Figure 21).

Improvements in engine design also made cruise missiles more practical. In 1967 the Williams International Corporation produced a small turbofan engine (12 inches in diameter, 24 inches long) that weighed less than 70 pounds and produced more than 400 pounds of thrust. New fuel

(margin note) Tercom guidance: the problem solved

mixtures offered more than 30-percent increases in fuel energy, which translated directly into extended range.

By the end of the Vietnam War, both the U.S. Navy and Air Force had cruise missile projects under way. At 19 feet three inches, the navy's sea-launched cruise missile (SLCM; eventually designated the Tomahawk) was 30 inches shorter than the air force's air-launched cruise missile (ALCM), but system components were quite similar and often from the same manufacturer (both missiles used the Williams engine and the McDonnell Douglas Corporation's Tercom). The Boeing Company produced the ALCM, while the General Dynamics Corporation produced the SLCM as well as the ground-launched cruise missile, or GLCM. The SLCM and GLCM were essentially the same configuration, differing only in their basing mode. The GLCM was designed to be launched from wheeled transporter-erector-launchers, while the SLCM was expelled from submarine tubes to the ocean surface in steel canisters or launched directly from armoured box launchers aboard surface ships. Both the SLCM and GLCM were propelled from their launchers or canisters by a solid-rocket booster, which dropped off after the wings and tail fins flipped out and the jet engine ignited. The ALCM, being dropped from a bomb-bay dispenser or wing pylon of a flying B-52 or B-1 bomber, did not require rocket boosting.

As finally deployed, the U.S. cruise missiles were intermediate-range weapons that flew at an altitude of 100 feet to a range of 1,500 miles. The SLCM was produced in three versions: a tactical-range (275-mile) antiship missile, with a combination of inertial guidance and active radar homing and with a high-explosive warhead; and two intermediate-range land-attack versions, with combined inertial and Tercom guidance and with either a high-explosive or a 200-kiloton nuclear warhead. The ALCM carried the same nuclear warhead as the SLCM, while the GLCM carried a low-yield warhead of 10 to 50 kilotons.

The ALCM entered service in 1982 and the SLCM in 1984. The GLCM was first deployed to Europe in 1983, but all GLCMs were dismantled after the signing of the INF Treaty.

Although their small size and low flight paths made the ALCM and SLCM difficult to detect by radar (the ALCM presented a radar cross section only one one-thousandth that of the B-52 bomber), their subsonic speed of about 500 miles per hour made them vulnerable to air defenses once they were detected. For this reason, the U.S.

Figure 21: *Flight path of a cruise missile.*
Limited to subsonic speeds, the missile would rely on its small size and ground-hugging flight profile to evade detection. U.S. cruise missiles, guided by a digitalized map of the terrain along their routes, could strike their targets with a nuclear warhead after being launched from 1,500 miles away.

Air Force began production of an advanced cruise missile, which would incorporate stealth technologies such as radar-absorbent materials and smooth, nonreflective surface shapes. The advanced cruise missile would have a range of over 1,800 miles.   (S.O.F.)

Nuclear weapons

Nuclear weapons derive their enormous explosive force from either the fission or fusion of atomic nuclei. Their significance may best be appreciated by the coining of the words kiloton (1,000 tons) and megaton (one million tons) to describe their blast effect in equivalent weights of TNT. For example, the first nuclear fission bomb, the one dropped on Hiroshima, Japan, in 1945, released energy equaling 15,000 tons (15 kilotons) of chemical explosive from less than 130 pounds (60 kilograms) of uranium. Fusion bombs, on the other hand, have given yields up to almost 60 megatons. The first nuclear weapons were bombs delivered by aircraft; warheads for strategic ballistic missiles, however, have become by far the most important nuclear weapons (see above *Strategic missiles*). There are also smaller tactical nuclear weapons that include artillery projectiles, demolition munitions (land mines), antisubmarine depth bombs, torpedoes, and short-range ballistic and cruise missiles. The U.S. stockpile of nuclear weapons reached its peak in 1967 with more than 32,000 warheads of 30 different types; the Soviet stockpile reached its peak of about 33,000 warheads in 1988.

Principles of fission and fusion

The basic principle of nuclear fission weapons (also called atomic bombs) involves the assembly of a sufficient amount of fissile material (*e.g.,* the uranium isotope uranium-235 or the plutonium isotope plutonium-239) to "go supercritical"—that is, for neutrons (which cause fission and are in turn released during fission) to be produced at a much faster rate than they can escape from the assembly. There are two ways in which a subcritical assembly of fissionable material can be rendered supercritical and made to explode. The subcritical assembly may consist of two parts, each of which is too small to have a positive multiplication rate; the two parts can be shot together by a gun-type device. Alternatively, a subcritical assembly surrounded by a chemical high explosive may be compressed into a supercritical one by detonating the explosive.

The basic principle of the fusion weapon (also called the thermonuclear or hydrogen bomb) is to produce ignition conditions in a thermonuclear fuel such as deuterium, an isotope of hydrogen with double the weight of normal hydrogen, or lithium deuteride. The Sun may be considered a thermonuclear device; its main fuel is deuterium, which it consumes in its core at temperatures of 18,000,000° to 36,000,000° F (10,000,000° to 20,000,000° C). To achieve comparable temperatures in a weapon, a fission triggering device is used.

THE DEVELOPMENT OF FISSION WEAPONS

Following the discovery of artificial radioactivity in the 1930s, the Italian physicist Enrico Fermi performed a series of experiments in which he exposed many elements to low-velocity neutrons. When he exposed thorium and uranium, chemically different radioactive products resulted, indicating that new elements had been formed, rather than merely isotopes of the original elements. Fermi concluded that he had produced elements beyond uranium (element 92), then the last element in the periodic table; he called them transuranic elements and named two of them ausenium (element 93) and hesperium (element 94). During the autumn of 1938, however, when Fermi was receiving the Nobel Prize for his work, Otto Hahn and Fritz Strassmann of Germany discovered that one of the "new" elements was actually barium (element 56).

Discovery of uranium fission

The Danish scientist Niels Bohr visited the United States in January 1939, carrying with him an explanation, devised by the Austrian refugee scientist Lise Meitner and her nephew Otto Frisch, of the process behind Hahn's surprising data. Low-velocity neutrons caused the uranium nucleus to fission, or break apart, into two smaller pieces; the combined atomic numbers of the two pieces—for example, barium and krypton—equalled that of the uranium nucleus. Much energy was released in the process. This news set off experiments at many laboratories. Bohr worked with John Wheeler at Princeton; they postulated that the uranium isotope uranium-235 was the one undergoing fission; the other isotope, uranium-238, merely absorbed the neutrons. It was discovered that neutrons were produced during the fission process; on the average, each fissioning atom produced more than two neutrons. If the proper amount of material were assembled, these free neutrons might create a chain reaction. Under special conditions, a very fast chain reaction might produce a very large release of energy; in short, a weapon of fantastic power might be feasible.

The first atomic bomb. The possibility that such a weapon might first be developed by Nazi Germany alarmed many scientists and was drawn to the attention of President Franklin D. Roosevelt by Albert Einstein, then living in the United States. The president appointed an Advisory Committee on Uranium; it reported that a chain reaction in uranium was possible, though unproved. Chain-reaction experiments with carbon and uranium were started in New York City at Columbia University, and in March 1940 it was confirmed that the isotope uranium-235 was responsible for low-velocity neutron fission in uranium. The Advisory Committee on Uranium increased its support of the Columbia experiments and arranged for a study of possible methods for separating the uranium-235 isotope from the much more abundant uranium-238. (Normal uranium contains approximately 0.7 percent uranium-235, most of the remainder being uranium-238.) The centrifuge process, in which the heavier isotope is spun to the outside, as in a cream separator, at first seemed the most useful, but at Columbia a rival process was proposed. In that process, gaseous uranium hexafluoride is diffused through barriers, or filters; more molecules containing the lighter isotope, uranium-235, would pass through the filter than those containing the heavier isotope, slightly enriching the mixture on the far side. A sequence of several thousand stages would be needed to enrich the mixture to 90 percent uranium-235; the total barrier area would be many acres.

During the summer of 1940, Edwin McMillan and Philip Abelson of the University of California at Berkeley discovered element 93, named neptunium; they inferred that this element would decay into element 94. The Bohr and Wheeler fission theory suggested that one of the isotopes, mass number 239, of this new element might also fission under low-velocity neutron bombardment. The cyclotron at the University of California at Berkeley was put to work to make enough element 94 for experiments; by mid-1941, element 94 had been firmly identified and named plutonium, and its fission characteristics had been established. Low-velocity neutrons did indeed cause it to undergo fission, and at a rate much higher than that of uranium-235. The Berkeley group, under Ernest Lawrence, was also considering producing large quantities of uranium-235 by turning one of their cyclotrons into a super mass spectrograph. A mass spectrograph employs a magnetic field to bend a current of uranium ions; the heavier ions (uranium-238) bend at a larger radius than the lighter ions (uranium-235), allowing the two separated currents to be collected in separate receivers.

Discovery of plutonium fission

In May 1941 a review committee reported that a nuclear explosive probably could not be available before 1945, that a chain reaction in natural uranium was probably 18 months off, and that it would take at least an additional year to produce enough plutonium for a bomb and three to five years to separate enough uranium-235. Further, it was held that all of these estimates were optimistic. In late June 1941 President Roosevelt established the Office of Scientific Research and Development under the direction of the scientist Vannevar Bush.

In the fall of 1941 the Columbia chain-reaction experiment with natural uranium and carbon yielded negative results. A review committee concluded that boron impurities might be poisoning it by absorbing neutrons. It was decided to transfer all such work to the University of Chicago and repeat the experiment there with high-purity

carbon. At Berkeley, the cyclotron, converted into a mass spectrograph (later called a calutron), was exceeding expectations in separating uranium-235, and it was enlarged to a 10-calutron system capable of producing one-tenth of an ounce (about three grams) of uranium-235 per day.

The U.S. entry into World War II in December 1941 was decisive in providing funds for a massive research and production effort for obtaining fissionable materials, and in May 1942 the momentous decision was made to proceed simultaneously on all promising production methods. Bush decided that the army should be brought into the production plant construction activities. The Corps of Engineers opened an office in New York City and named it the Manhattan Engineer District Office. After considerable argument over priorities, a workable arrangement was achieved with the formation of a three-man policy board chaired by Bush and the appointment on September 17 of Colonel Leslie Groves as head of the Manhattan Engineer District. Groves arranged contracts for a gaseous diffusion separation plant, a plutonium production facility, and a calutron pilot plant, which might be expanded later. The day before the success of Fermi's chain-reaction experiment at the University of Chicago on Dec. 2, 1942, Groves (now a brigadier general) signed the construction contract for the plutonium production reactors. Many problems were still unsolved, however. First, the gaseous diffusion barrier had not yet been demonstrated as practical. Second, Berkeley had been successful with its empirically designed calutron, but the Oak Ridge pilot plant contractors were understandably uneasy about the rough specifications available for the massive apparatus of uranium-235, which was designated the Y-12 effort. Third, plutonium chemistry was almost unknown; in fact, it was not known whether or not plutonium gave off neutrons during fission, or, if so, how many.

Meantime, as part of the June 1942 reorganization, J. Robert Oppenheimer became, in October, the director of Project Y, the group that was to design the actual weapon. This effort was spread over several locations. On November 16 Groves and Oppenheimer visited the former Los Alamos Ranch School, some 60 miles (100 kilometres) north of Albuquerque, N.M., and on November 25 Groves approved it as the site for the Los Alamos Scientific Laboratory. By July two essential and encouraging pieces of experimental data had been obtained—plutonium did give off neutrons in fission, more than uranium-235; and the neutrons were emitted in a short time compared to that needed to bring the weapon materials into a supercritical assembly. The theorists contributed one discouraging note: their estimate of the critical mass for uranium-235 had risen over threefold, to something between 50 and 100 pounds.

The emphasis during the summer and fall of 1943 was on the gun method of assembly, in which the projectile, a subcritical piece of uranium-235 (or plutonium-239), would be placed in a gun barrel and fired into the target, another subcritical piece of uranium-235. After the mass was joined (and now supercritical), a neutron source would be used to start the chain reaction. A problem developed with applying the gun method to plutonium, however. In manufacturing plutonium-239 from uranium-238 in a reactor, some of the plutonium-239 absorbs a neutron and becomes plutonium-240. This material undergoes spontaneous fission, producing neutrons. Some neutrons will always be present in a plutonium assembly and cause it to begin multiplying as soon as it goes critical, before it reaches supercriticality; it will then explode prematurely and produce comparatively little energy. The gun designers tried to beat this problem by achieving higher projectile speeds, but they lost out in the end to a better idea—the implosion method.

In April 1943 a Project Y physicist, Seth Neddermeyer, proposed to assemble a supercritical mass from many directions, instead of just two as in the gun. In particular, a number of shaped charges placed on the surface of a sphere would fire many subcritical pieces into one common ball at the centre of the sphere. John von Neumann, a mathematician who had had experience in shaped-charge, armour-piercing work, supported the implosion method

enthusiastically and pointed out that the greater speed of assembly might solve the plutonium-240 problem. The physicist Edward Teller suggested that the converging material might also become compressed, offering the possibility that less material would be needed. By late 1943 the implosion method was being given an increasingly higher priority; by July 1944 it had become clear that the plutonium gun could not be built. The only way to use plutonium in a weapon was by the implosion method.

By 1944 the Manhattan Project was spending money at a rate of more than $1 billion per year. The situation was likened to a nightmarish horse race; no one could say which of the horses (the calutron plant, the diffusion plant, or the plutonium reactors) was likely to win or whether any of them would even finish the race. In July 1944 the first Y-12 calutrons had been running for three months but were operating at less than 50 percent efficiency; the main problem was in recovering the large amounts of material that reached neither the uranium-235 nor uranium-238 boxes and, thus, had to be rerun through the system. The gaseous diffusion plant was far from completion, the production of satisfactory barriers remaining the major problem. And the first plutonium reactor at Hanford, Wash., had been turned on in September, but it had promptly turned itself off. Solving this problem, which proved to be caused by absorption of neutrons by one of the fission products, took several months. These delays meant almost certainly that the war in Europe would be over before the weapon could be ready. The ultimate target was slowly changing from Germany to Japan.

Within 24 hours of Roosevelt's death on April 12, 1945, President Harry S. Truman was told briefly about the atomic bomb by Secretary of War Henry Stimson. On April 25 Stimson, with Groves's assistance, gave Truman a more extensive briefing on the status of the project: the uranium-235 gun design had been frozen, but sufficient uranium-235 would not be accumulated until around August 1. Enough plutonium-239 would be available for an implosion assembly to be tested in early July; a second would be ready in August. Several B-29s had been modified to carry the weapons, and support construction was under way at Tinian, in the Mariana Islands, 1,500 miles south of Japan.

The test of the plutonium weapon was named Trinity; it was fired at 5:29:45 AM (local time) on July 16, 1945, at the Alamogordo Bombing Range in south central New Mexico. The theorists' predictions of the energy release ranged from the equivalent of less than 1,000 tons of TNT to 45,000 tons. The test produced an energy, or yield, equivalent to 21,000 tons of TNT.

A single B-29 bomber, named the *Enola Gay*, flew over Hiroshima, Japan, on Monday, Aug. 6, 1945, at 8:15 in the morning, local time. The untested uranium-235 gun-assembly bomb, nicknamed Little Boy, was air-burst 1,900 feet (680 metres) above the city to maximize destruction. Two-thirds of the city area was destroyed. The population actually present at the time was estimated at 350,000; of these, 140,000 died by the end of the year. The second weapon, a duplicate of the plutonium-239 implosion assembly tested in Trinity and nicknamed Fat Man, was to be dropped on Kokura on August 11; a third was being prepared in the United States for possible use in late August or early September. To avoid bad weather, the schedule was moved up two days to August 9. The B-29, named *Bock's Car*, spent 10 minutes over Kokura without sighting its aim point; it then proceeded to the secondary target of Nagasaki, where, at 11:02 AM local time, the weapon was air-burst at 1,650 feet with a force later estimated at 21 kilotons. About half the city was destroyed, and, of the estimated 270,000 people present at the time, about 70,000 died by the end of the year.

The spread of atomic weapons. Scientists in several countries performed experiments in connection with nuclear reactors and fission weapons during World War II, but no country other than the United States carried its projects as far as separating uranium-235 or manufacturing plutonium-239.

The Axis powers. By the time the war began on Sept. 1, 1939, Germany had a special office for the military

(margin notes, left column:) The Manhattan Project

(margin notes, left column:) The triggering methods

(margin notes, right column:) The dropping of the bomb

application of nuclear fission: chain-reaction experiments with uranium and carbon were being planned, and ways of separating the uranium isotopes were under study. Some measurements on carbon, later shown to be in error, led the physicist Werner Heisenberg to recommend that heavy water be used, instead, for the moderator. This dependence on scarce heavy water was a major reason the German experiments never reached a successful conclusion. The isotope separation studies were oriented toward low enrichments (about 1 percent uranium-235) for the chain reaction experiments; they never got past the laboratory apparatus stage, and several times these prototypes were destroyed in bombing attacks. As for the fission weapon itself, it was a rather distant goal, and practically nothing but "back-of-the-envelope" studies were done on it.

German difficulties *(margin)*

Like their counterparts elsewhere, Japanese scientists initiated research on an atomic bomb. In December 1940, Japan's leading scientist, Nishina Yoshio, undertook a small-scale research effort supported by the armed forces. It did not progress beyond the laboratory owing to lack of government support, resources, and uranium.

Great Britain. The British weapon project started informally, as in the United States, among university physicists. In April 1940 a short paper by Otto Frisch and Rudolf Peierls, expanding on the idea of critical mass, estimated that a superweapon could be built using several pounds of pure uranium-235 and that this amount of material might be obtainable from a chain of diffusion tubes. This three-page memorandum was the first report to foretell with scientific conviction the practical possibility of making a bomb and the horrors it would bring. A group of scientists known as the MAUD committee was set up in the Ministry of Aircraft Production in April 1940 to decide if a uranium bomb could be made. The committee approved a report on July 15, 1941, concluding that the scheme for a uranium bomb was practicable, that work should continue on the highest priority, and that collaboration with the Americans should be continued and expanded. As the war took its toll on the economy, the British position evolved through 1942 and 1943 to one of full support for the American project with the realization that Britain's major effort would come after the war. While the British program was sharply reduced at home, approximately 50 scientists and engineers went to the United States at the end of 1943 and during 1944 to work on various aspects of the Manhattan Project. The valuable knowledge and experience they acquired sped the development of the British bomb after 1945.

The formal postwar decision to manufacture a British atomic bomb was made by Prime Minister Clement Attlee's government during a meeting of the Defence Subcommittee of the Cabinet in early January 1947. The construction of a first reactor to produce fissile material and associated facilities had gotten under way the year before. William Penney, a member of the British team at Los Alamos during the war, was placed in charge of fabricating and testing the bomb, which was to be of a plutonium type similar to the one dropped on Nagasaki. That Britain was developing nuclear weapons was not made public until Prime Minister Winston Churchill announced on Feb. 17, 1952, plans to test the first British-made atomic bomb at the Monte Bello Islands off the northwest coast of Australia. There, on Oct. 3, 1952, the first British atomic weapons test, called Hurricane, was successfully conducted aboard the frigate HMS *Plym.* By early 1954 Royal Air Force Canberra bombers were armed with atomic bombs.

The British test *(margin)*

The Soviet Union. In the decade before the war, Soviet physicists were actively engaged in nuclear and atomic research. By 1939 they had established that, once uranium has been fissioned, each nucleus emits neutrons and can therefore, at least in theory, begin a chain reaction. The following year, physicists concluded that such a chain reaction could be ignited in either natural uranium or its isotope, uranium-235, and that this reaction could be sustained and controlled with a moderator such as heavy water. In June 1940 the Soviet Academy of Sciences established the Uranium Commission to study the "uranium problem."

In February 1939, news had reached Soviet physicists of the discovery of nuclear fission in the West. The military implications of such a discovery were immediately apparent, but Soviet research was brought to a halt by the German invasion in June 1941. In early 1942 the physicist Georgy N. Flerov noticed that articles on nuclear fission were no longer appearing in western journals; this indicated that research on the subject had become secret. In response, Flerov wrote to, among others, Premier Joseph Stalin, insisting that "we must build the uranium bomb without delay." In 1943 Stalin ordered the commencement of a research project under the supervision of Igor V. Kurchatov, who had been director of the nuclear physics laboratory at the Physico-Technical Institute in Leningrad. Kurchatov initiated work on three fronts: achieving a chain reaction in a uranium pile, designing both uranium-235 and plutonium bombs, and separating isotopes from these materials.

By the end of 1944, 100 scientists were working under Kurchatov, and by the time of the Potsdam Conference, which brought the Allied leaders together the day after the Trinity test, the project on the atomic bomb was seriously under way. During one session at the conference, Truman remarked to Stalin that the United States had built a "new weapon of unusual destructive force." Stalin replied that he would like to see the United States make "good use of it against the Japanese."

Upon his return from Potsdam, Stalin ordered that work on the fission bomb proceed at a faster pace. On Aug. 7, 1945, the day after the bombing of Hiroshima, he placed Lavrenty P. Beria, the chief of secret police, in charge of the Soviet version of the Manhattan Project. The first Soviet chain reaction took place in Moscow on Dec. 25, 1946, using an experimental graphite-moderated natural uranium pile, and the first plutonium production reactor became operational at Kyshtym, in the Ural Mountains, on June 19, 1948. The first Soviet weapon test occurred on Aug. 29, 1949, using plutonium; it had a yield of 10 to 20 kilotons.

The first Soviet device *(margin)*

France. French scientists, such as Henri Becquerel, Marie and Pierre Curie, and Frédéric and Irène Joliot-Curie, made important contributions to 20th-century atomic physics. During World War II several French scientists participated in an Anglo-Canadian project in Canada, where eventually a heavy water reactor was built at Chalk River, Ont., in 1945.

On Oct. 18, 1945, the Atomic Energy Commission (Commissariat à l'Énergie Atomique; CEA) was established by General Charles de Gaulle with the objective of exploiting the scientific, industrial, and military potential of atomic energy. The military application of atomic energy did not begin until 1951. In July 1952 the National Assembly adopted a five-year plan, a primary goal of which was to build plutonium production reactors. Work began on a reactor at Marcoule in the summer of 1954 and on a plutonium separating plant the following year.

On Dec. 26, 1954, the issue of proceeding with a French bomb was raised at Cabinet level. The outcome was that Prime Minister Pierre Mendès-France launched a secret program to develop a bomb. On Nov. 30, 1956, a protocol was signed specifying tasks the CEA and the Defense Ministry would perform. These included providing the plutonium, assembling a device, and preparing a test site. On July 22, 1958, de Gaulle, who had resumed power as prime minister, set the date for the first atomic explosion to occur within the first three months of 1960. On Feb. 13, 1960, the French detonated their first atomic bomb from a 330-foot tower in the Sahara in what was then French Algeria.

China. On Jan. 15, 1955, Mao Zedong (Mao Tse-tung) and the Chinese leadership decided to obtain their own nuclear arsenal. From 1955 to 1958 the Chinese were partially dependent upon the Soviet Union for scientific and technological assistance, but from 1958 until the break in relations in 1960 they became more and more self-sufficient. Facilities were built to produce and process uranium and plutonium at the Lan-chou Gaseous Diffusion Plant and the Chiu-ch'üan Atomic Energy Complex, both in the northwestern province of Kansu. A design laboratory

(called the Ninth Academy) was established at Hai-yen, east of the Koko Nor in Tsinghai province. A test site at Lop Nor, in far northwestern China, was established in October 1959. Overall leadership and direction was provided by Nie Rongzhen (Nieh Jung-chen), director of the Defense Science and Technology Commission.

Unlike the initial U.S. or Soviet tests, the first Chinese detonation—on Oct. 16, 1964—used uranium-235 in an implosion-type configuration. Plutonium was not used until the eighth explosion, on Dec. 27, 1968.

Other countries. On May 18, 1974, India detonated a nuclear device in the Rājasthān desert near Pokaran with a reported yield of 15 kilotons. India characterized the test as being for peaceful purposes and apparently did not stockpile weapons. Pakistan declared its nuclear program to be solely for peaceful purposes, but it acquired the necessary infrastructure of facilities to produce weapons and was generally believed to possess them.

Nuclear proliferation

Several other countries were believed to have built nuclear weapons or to have acquired the capability of assembling them on short notice. Israel was believed to have built an arsenal of more than 200 weapons, including thermonuclear bombs. In August 1988 the South African foreign minister said that South Africa had "the capability to [produce a nuclear bomb] should we want to." Argentina, Brazil, South Korea, and Taiwan also had the scientific and industrial base to develop and produce nuclear weapons, but they did not seem to have active programs. (W.J.F./T.B.C./R.S.N.)

THE DEVELOPMENT OF FUSION WEAPONS

The United States. U.S. research on thermonuclear weapons started from a conversation in September 1941 between Fermi and Teller. Fermi wondered if the explosion of a fission weapon could ignite a mass of deuterium sufficiently to begin thermonuclear fusion. (Deuterium, an isotope of hydrogen with one proton and one neutron in the nucleus—*i.e.,* twice the normal weight—makes up 0.015 percent of natural hydrogen and can be separated in quantity by electrolysis and distillation. It exists in liquid form only below about −417° F, or −250° C.) Teller undertook to analyze the thermonuclear processes in some detail and presented his findings to a group of theoretical physicists convened by Oppenheimer in Berkeley in the summer of 1942. One participant, Emil Konopinski, suggested that the use of tritium be investigated as a thermonuclear fuel, an insight that would later be important to most designs. (Tritium, an isotope of hydrogen with one proton and two neutrons in the nucleus—*i.e.,* three times the normal weight—does not exist in nature except in trace amounts, but it can be made by irradiating lithium

in a nuclear reactor. It is radioactive and has a half-life of 12.5 years.)

As a result of these discussions the participants concluded that a weapon based on thermonuclear fusion was possible. When the Los Alamos laboratory was being planned, a small research program on the Super, as it came to be known, was included. Several conferences were held at the laboratory in late April 1943 to acquaint the new staff members with the existing state of knowledge and the direction of the research program. The consensus was that modest thermonuclear research should be pursued along theoretical lines. Teller proposed more intensive investigations, and some work did proceed, but the more urgent task of developing a fission weapon always took precedence—a necessary prerequisite for a hydrogen bomb in any event.

In the fall of 1945, after the success of the atomic bomb and the end of World War II, the future of the Manhattan Project, including Los Alamos and the other facilities, was unclear. Government funding was severely reduced, many scientists returned to universities and to their careers, and contractor companies turned to other pursuits. The Atomic Energy Act, signed by President Truman on Aug. 1, 1946, established the Atomic Energy Commission (AEC), replacing the Manhattan Engineer District, and gave it civilian authority over all aspects of atomic energy, including oversight of nuclear warhead research, development, testing, and production.

From April 18 to 20, 1946, a conference led by Teller at Los Alamos reviewed the status of the Super. At that time it was believed that a fission weapon could be used to ignite one end of a cylinder of liquid deuterium and that the resulting thermonuclear reaction would self-propagate to the other end. This conceptual design was known as the "classical Super."

Design problems of a thermonuclear bomb

One of the two central design problems was how to ignite the thermonuclear fuel. It was recognized early on that a mixture of deuterium and tritium theoretically could be ignited at lower temperatures and would have a faster reaction time than deuterium alone, but the question of how to achieve ignition remained unresolved. The other problem, equally difficult, was whether and under what conditions burning might proceed in thermonuclear fuel once ignition had taken place. An exploding thermonuclear weapon involves many extremely complicated, interacting physical and nuclear processes. The speeds of the exploding materials can be up to millions of feet per second, temperatures and pressures are greater than those at the centre of the Sun, and time scales are billionths of a second. To resolve whether the "classical Super" or any other design would work required accurate numerical models of these processes—a formidable task, since the computers that would be needed to perform the calculations were still under development. Also, the requisite fission triggers were not yet ready, and the limited resources of Los Alamos could not support an extensive program.

On Sept. 23, 1949, Truman announced that "we have evidence that within recent weeks an atomic explosion occurred in the U.S.S.R." This first Soviet test stimulated an intense, four-month, secret debate about whether to proceed with the hydrogen bomb project. One of the strongest statements of opposition against proceeding with a hydrogen bomb program came from the General Advisory Committee (GAC) of the AEC, chaired by Oppenheimer. In their report of Oct. 30, 1949, the majority recommended "strongly against" initiating an all-out effort, believing "that extreme dangers to mankind inherent in the proposal wholly outweigh any military advantages that could come from this development." "A super bomb," they went on to say, "might become a weapon of genocide." They believed that "a super bomb should never be produced." Nevertheless, the Joint Chiefs of Staff, the State and Defense departments, the Joint Committee on Atomic Energy, and a special subcommittee of the National Security Council all recommended proceeding with the hydrogen bomb. Truman announced on Jan. 31, 1950, that he had directed the AEC to continue its work on all forms of atomic weapons, including hydrogen bombs. In March, Los Alamos went on a six-day workweek.

Figure 22: *Idealized representations of four nuclear weapon designs.*
A fission bomb using the implosion method (A) was dropped on Nagasaki; a gun-assembly design (B) destroyed Hiroshima. Boosted-fission designs (C) are the principal means of triggering modern thermonuclear weapons. Most modern nuclear weapons are multistage thermonuclear designs (D).

In the months that followed Truman's decision, the prospect of actually being able to build a hydrogen bomb became less and less likely. The mathematician Stanislaw M. Ulam, with the assistance of Cornelius J. Everett, had undertaken calculations of the amount of tritium that would be needed for ignition of the classical Super. Their results were spectacular and, to Teller, discouraging: the amount needed was estimated to be enormous. In the summer of 1950 more detailed and thorough calculations by other members of the Los Alamos Theoretical Division confirmed Ulam's estimates. This meant that the cost of the Super program would be prohibitive.

Also in the summer of 1950, Fermi and Ulam calculated that liquid deuterium probably would not burn—that is, there would probably be no self-sustaining and propagating reaction. Barring surprises, therefore, the theoretical work to 1950 indicated that every important assumption regarding the viability of the classical Super was wrong. If success was to come, it would have to be accomplished by other means.

Solving the problem of ignition   The other means became apparent between February and April 1951, following breakthroughs achieved at Los Alamos. One breakthrough was the recognition that the burning of thermonuclear fuel would be more efficient if a high density were achieved throughout the fuel prior to raising its temperature, rather than the classical Super approach of just raising the temperature in one area and then relying on the propagation of thermonuclear reactions to heat the remaining fuel. A second breakthrough was the recognition that these conditions—high compression and high temperature throughout the fuel—could be achieved by containing and converting the radiation from an exploding fission weapon and then using this energy to compress a separate component containing the thermonuclear fuel.

The major figures in these breakthroughs were Ulam and Teller. In December 1950 Ulam had proposed a new fission weapon design, using the mechanical shock of an ordinary fission bomb to compress to a very high density a second fissile core. (This two-stage fission device was conceived entirely independently of the thermonuclear program, its aim being to use fissionable materials more economically.) Early in 1951 Ulam went to see Teller and proposed that the two-stage approach be used to compress and ignite a thermonuclear secondary. Teller suggested radiation implosion, rather than mechanical shock, as the mechanism for compressing the thermonuclear fuel in the second stage. On March 9, 1951, Teller and Ulam presented a report containing both alternatives, entitled "On Heterocatalytic Detonations I. Hydrodynamic Lenses and Radiation Mirrors." A second report, dated April 4, by Teller, included some extensive calculations by Frederic de Hoffmann and elaborated on how a thermonuclear bomb could be constructed. The two-stage radiation implosion design proposed by these reports, which led to the modern concept of thermonuclear weapons, became known as the Teller–Ulam configuration.

It was immediately clear to all scientists concerned that these new ideas—achieving a high density in the thermonuclear fuel by compression using a fission primary—provided for the first time a firm basis for a fusion weapon. Without hesitation, Los Alamos adopted the new program. Gordon Dean, chairman of the AEC, convened a meeting at the Institute for Advanced Study in Princeton, hosted by Oppenheimer, on June 16–18, 1951, where the new idea was discussed. In attendance were the GAC members, AEC commissioners, and key scientists and consultants from Los Alamos and Princeton. The participants were unanimously in favour of active and rapid pursuit of the Teller–Ulam principle.

Just prior to the conference, on May 8 at Enewetak atoll in the western Pacific, a test explosion called George had successfully used a fission bomb to ignite a small quantity of deuterium and tritium. The original purpose of George had been to confirm the burning of these thermonuclear fuels (about which there had never been any doubt), but with the new conceptual understanding contributed by Teller and Ulam, the test provided the bonus of successfully demonstrating radiation implosion.

In September 1951, Los Alamos proposed a test of the Teller–Ulam concept for November 1952. Engineering of the device, nicknamed Mike, began in October 1951, but unforeseen difficulties required a major redesign of the experiment in March 1952. The Mike device weighed 82 tons, owing in part to cryogenic (low-temperature) refrigeration equipment necessary to keep the deuterium in liquid form. It was successfully detonated during Operation Ivy, on Nov. 1, 1952 (local time), at Enewetak. The explosion achieved a yield of 10.4 million tons of TNT, or 500 times larger than the Nagasaki bomb, and it produced a crater 6,240 feet in diameter and 164 feet deep.

The first thermonuclear explosion

With the Teller–Ulam configuration proved, deliverable thermonuclear weapons were designed and initially tested during Operation Castle in 1954. The first test of the series, conducted on March 1, 1954 (local time), was called Bravo. It used solid lithium deuteride rather than liquid deuterium and produced a yield of 15 megatons, 1,000 times as large as the Hiroshima bomb. Here the principal thermonuclear reaction was the fusion of deuterium and tritium. The tritium was produced in the weapon itself by neutron bombardment of the lithium-6 isotope in the course of the fusion reaction. Using lithium deuteride instead of liquid deuterium eliminated the need for cumbersome cryogenic equipment.

With completion of Castle, the feasibility of lightweight, solid-fuel thermonuclear weapons was proved. Vast quantities of tritium would not be needed after all. New possibilities for adaptation of thermonuclear weapons to various kinds of missiles began to be explored.

The Soviet Union. In 1948 Kurchatov organized a theoretical group, under the supervision of physicist Igor Y. Tamm, to begin work on a fusion bomb. (This group included Andrey Sakharov, who, after contributing several important ideas to the effort, later became known as the "father of the Soviet H-bomb.") In general, the Soviet program was two to three years behind that of the United States. The test that took place on Aug. 12, 1953, produced a fusion reaction in lithium deuteride and had a yield of 200 to 400 kilotons. This test, however, was not of a high-yield hydrogen bomb based on the Teller–Ulam configuration or something like it. The first such Soviet test, with a yield in the megaton range, took place on Nov. 22, 1955. On Oct. 30, 1961, the Soviet Union tested the largest known nuclear device, with an explosive force of 58 megatons.

Great Britain. Minister of Defence Harold Macmillan announced in his Statement of Defence, on Feb. 17, 1955, that the United Kingdom planned to develop and produce hydrogen bombs. The formal decision to proceed had been made earlier in secret by a small Defence subcommittee on June 16, 1954, and put to the Cabinet in July. The decision was unaccompanied by the official debate that characterized the American experience five years earlier.

It remained unclear exactly when the first British thermonuclear test occurred. Three high-yield tests in May and June 1957 near Malden Island in the Pacific Ocean were probably of boosted fission designs (see below). The most likely date for the first two-stage thermonuclear test, using the Teller–Ulam configuration or a variant, was Nov. 8, 1957. This test and three others that followed in April and September 1958 contributed novel ideas to modern thermonuclear designs.

British testing

France. Well before their first atomic test, the French assumed they would eventually have to become a thermonuclear power as well. The first French thermonuclear test was conducted on Aug. 24, 1968.

China. Plans to proceed toward a Chinese hydrogen bomb were begun in 1960, with the formation of a group by the Institute of Atomic Energy to do research on thermonuclear materials and reactions. In late 1963, after the design of the fission bomb was complete, the Theoretical Department of the Ninth Academy, under the direction of Deng Jiaxian (Teng Chia-hsien), was ordered to shift to thermonuclear work. By the end of 1965 the theoretical work for a multistage bomb had been accomplished. After testing two boosted fission devices in 1966, the first Chinese multistage fusion device was detonated on June 17, 1967.

From the late 1940s, U.S. nuclear weapon designers developed and tested warheads to improve their ballistics, to standardize designs for mass production, to increase yields, to improve yield-to-weight and yield-to-volume ratios, and to study their effects. These improvements resulted in the creation of nuclear warheads for a wide variety of strategic and tactical delivery systems.

Fission. The first advances came through the test series Operation Sandstone, conducted in the spring of 1948. These three tests used implosion designs of a second generation, which incorporated composite and levitated cores. A composite core consisted of concentric shells of both uranium-235 and plutonium-239, permitting more efficient use of these fissile materials. Higher compression of the fissile material was achieved by levitating the core—that is, introducing an air gap into the weapon to obtain a higher yield for the same amount of fissile material.

Tests during Operation Ranger in early 1951 included implosion devices with cores containing a fraction of a critical mass—a concept originated in 1944 during the Manhattan Project. Unlike the original Fat Man design, these "fractional crit" weapons relied on compressing the fissile core to a higher density in order to achieve a supercritical mass. These designs could achieve appreciable yields with less material.

Boosted reactions

One technique for enhancing the yield of a fission explosion was called "boosting." Boosting referred to a process whereby thermonuclear reactions were used as a source of neutrons for inducing fissions at a much higher rate than could be achieved with neutrons from fission chain reactions alone. The concept was invented by Teller by the middle of 1943. By incorporating deuterium and tritium into the core of the fissile material, a higher yield could be obtained from a given quantity of fissile material—or, alternatively, the same yield could be achieved with a smaller amount. The fourth test of Operation Greenhouse, on May 24, 1951, was the first proof test of a booster design. In subsequent decades approximately 90 percent of nuclear weapons in the U.S. stockpile relied on boosting.

Fusion. Refinements of the basic two-stage Teller–Ulam configuration resulted in thermonuclear weapons with a wide variety of characteristics and applications. Some high-yield deliverable weapons incorporated additional thermonuclear fuel (lithium deuteride) and fissionable material (uranium-235 and uranium-238) in a third stage. While there was no theoretical limit to the yield that could be achieved from a thermonuclear bomb (for example, by adding more stages), there were practical limits on the size and weight of weapons that could be carried by aircraft or missiles. The largest U.S. bombs had yields of from 10 to 20 megatons and weighed up to 20 tons. Beginning in the early 1960s, however, the United States built a variety of smaller, lighter weapons that exhibited steadily improving yield-to-weight and yield-to-volume ratios.

The neutron bomb

A nuclear explosion releases energy in a variety of forms, including blast, heat, and radiation (X rays, gamma rays, and neutrons). By varying a weapon's design, these effects could be tailored for a specific military purpose. In an enhanced-radiation weapon, more commonly called a neutron bomb, the objective was to minimize the blast by reducing the fission yield and to enhance the neutron radiation. Such a weapon would prove lethal to invading troops without, it was hoped, destroying the defending country's towns and countryside. It was actually a small (on the order of one kiloton), two-stage thermonuclear weapon that utilized deuterium and tritium, rather than lithium deuteride, to maximize the release of fast neutrons. The first U.S. application of this principle was an antiballistic missile warhead in the mid-1970s. Enhanced-radiation warheads were produced for the Lance short-range ballistic missile and for an eight-inch artillery shell.

(T.B.C./R.S.N.)

Chemical and biological weapons

CHEMICAL WARFARE

Chemical warfare agents are substances, whether gaseous, liquid, or solid, intended for use in warfare because of their direct toxic effects on people, animals, or plants. Worldwide revulsion toward chemical weapons is embodied in the Geneva Protocol of 1925, prohibiting "the use in war of asphyxiating, poisonous or other gases, and of all analogous liquids, materials or devices." More than 140 states, including all major nations, are parties to the Protocol of 1925.

History of use. Toxic smokes and other toxic substances were used occasionally in war from ancient times, but the earliest large-scale use of chemical warfare agents was in World War I. Preceded by both sides' sporadic use of various tear gases in artillery and other projectiles starting in 1914, it was the German attack with chlorine released from thousands of cylinders along a four-mile (six-kilometre) front at Ypres on April 22, 1915, that initiated the massive use of chemicals in that conflict. The wind-borne cloud totally broke the lines of the unprepared French Territorial and Algerian units in its path, but the attackers failed to exploit the opportunity. Although numerous chlorine gas-cloud attacks were subsequently carried out by both sides, they accomplished little, owing to the introduction of gas masks and other protective measures.

Chlorine in World War I

As other gases and more effective delivery methods were introduced, so too were improved defenses. Notable among offensive improvements were respiratory agents more poisonous than chlorine, such as phosgene, and chemicals that blistered the skin and attacked the eyes, especially mustard gas. The defense kept pace, with the introduction of better gas masks, protective clothing, and battlefield tactics for minimizing exposure. More than 100,000 tons of various chemical warfare agents were used in World War I; but gas was an unimportant weapon in overall military terms, largely because of the effectiveness of defenses against it.

In World War II, chemical weapons were stockpiled by both sides, but they were not used and were not integrated into military planning. Records indicated various reasons for this: (1) military opinion that chemical weapons would be no more effective than conventional weapons and would complicate and delay operations, (2) fear of retaliation, especially against civilian centres, and (3) aversion to gas warfare by political and military leaders, reflecting the proscriptions of the Geneva Protocol.

Chemical weapons were used in only a few of the more than 200 wars fought after World War I. In each case—as in Ethiopia (1935–36), China (1938–42), the Yemen (1966–67), and Iraq–Iran (1984–88)—chemicals were used against forces initially lacking gas masks.

The weapons. Modern lethal chemical weapons employed the organophosphorus nerve agents first produced but not used by Germany during World War II. Related to certain insecticides but much more toxic to man, they would cause intense sweating, filling of the bronchial passages with mucus, dimming of vision, uncontrollable vomiting and defecation, convulsions, and finally paralysis and respiratory failure. Death would result from asphyxia, generally within a few minutes after respiratory exposure or within hours if exposure was through a liquid nerve agent on the skin.

The U.S. stockpile of chemical warfare agents, loaded into munitions or stored in bulk, included the nerve agents sarin and VX, while the Soviet Union stocked the nerve agents sarin, VX, and soman. Of these three nerve agents (all liquids), sarin would evaporate the most rapidly and would pose mainly a respiratory hazard. VX, the least volatile, would act primarily as a contact poison. Soman, with volatility intermediate between that of sarin and VX, would pose both respiratory and contact hazards.

U.S. and Soviet nerve agents

In addition to nerve agents, both nations stocked mustard gas and the irritant CS, which was also used by police. The Soviets also stocked lewisite, a blister agent developed but not used by the United States during World War I. Mustard gas and lewisite would not be nearly so lethal as the nerve agents, causing casualties principally from incapacitating blisters and temporary blindness. Their full effects would take several hours to develop, although lewisite, in contrast to mustard gas, would cause immediate pain to the skin and eyes.

Liquid chemical warfare agents, such as mustard gas,

lewisite, and the nerve agents, could be loaded into artillery projectiles, bombs, or missile warheads, to be dispersed by an explosive charge as a vapour cloud or a liquid spray. Liquid agents might also be carried in tanks and sprayed from aircraft at low altitude. Greater persistence and more controlled dispersion might be obtained by the addition of thickeners. Solid agents, such as CS, might be dispersed explosively or aerosolized from pyrotechnic mixtures in various munitions.

An innovation put into quantity production by the United States in 1987 was the binary sarin artillery projectile, in which two relatively nontoxic precursors of sarin were held in separate canisters. Upon firing, the two chemicals would mix and react to form sarin. One of the canisters might be stored and shipped separately, to be inserted into the projectile at the ammunition depot or the gun site. This built-in safety feature was intended to provide greater operational flexibility in the storage and transport of the weapon. The binary principle could be applied to other types of chemical warfare agent.

The amount of a chemical warfare agent required to create a hazardous cloud over a target area would be highly dependent on air movements. The weight of sarin, for example, required to produce a lethal respiratory hazard to unprotected persons over most of an open mile-square area could be between 0.3 and 10 tons, depending on atmospheric conditions. As an illustration, the delivery of these amounts by 155-millimetre artillery would require the firing of approximately 100 to 3,000 projectiles.

For causing casualties to unprotected troops, chemicals could be more effective than an equivalent weight of conventional high-explosive fragmentation weapons. For troops with good protection, however, the reverse would be true; soldiers with modern antichemical protection would be far less vulnerable to chemicals than to conventional weapons.

Defense. The first and most important line of defense against chemical warfare agents (also needed for protection against radioactive fallout) was the individual protection provided by masks and protective clothing, and the collective protection of combat vehicles and mobile or fixed shelters. Filters for masks and shelters contained specially treated activated charcoal to remove vapours, and paper membranes or other materials to remove particles. Such *Effec- filters typically could reduce the concentration of chemi- tiveness cal (and biological) warfare agents by a factor of at least of masks 100,000. Masks could be donned in less than 10 seconds and over- and could be worn for long periods, even in sleep. Modern garments protective overgarments were made of fabric containing activated charcoal or other adsorptive forms of carbon. A complete suit typically weighed about four pounds (two kilograms). The fabric could breathe and pass water-vapour perspiration. In warm weather, periods of heavy exertion in full protective gear would have to be limited in order to avoid heat stress, or else protection would have to be partly relaxed, as by partially opening the protective jacket. Under common European conditions, military units routinely exercised at or near full protection for several days continuously.

Other items for chemical defense were detectors and alarms sensitive to nerve and blister agents, prophylactic and antidote drugs that would provide partial protection against nerve agents, and equipment for decontaminating people and equipment.

The effectiveness of chemical weapons against prepared forces would depend more on the interference with fighting performance imposed by wearing protective equipment and taking other precautions than on direct casualties. The extent of such interference, and hence the military value of chemicals in comparison with other weapons, was difficult to assess. Estimates, based on controlled field exercises, of the reduction in performance in military units under chemical attack ranged from near zero to more than 30 percent, depending on the mission and the conditions of the exercise.

BIOLOGICAL WARFARE

Biological warfare agents are infectious microbes, including viruses, bacteria, and fungi, intended for use in warfare

because of their pathogenic effects on people, animals, or plants. The development, production, and stockpiling *Banning of of weapons based on them were outlawed by the 1972 biological Biological Weapons Convention, to which more than 100 weapons states were party, including all five permanent members of the United Nations Security Council. The treaty also covered weapons based on naturally occurring poisons, known as toxins, however produced. As with chemical weapons, actual employment of biological weapons was outlawed by the 1925 Geneva Protocol.

At the time of their destruction in accordance with presidential directives of 1969 and 1970, the biological weapons of the United States (the only country for which authenticated information was available) included dry-powder or liquid-slurry formulations of the microbes that cause tularemia, Q fever, Venezuelan equine encephalitis, rice blast, and stem rust of wheat. They also included a number of toxins, such as paralytic shellfish poison. A variety of dispensers, both large and small, was also on hand.

Biological weapons designed to dispense airborne clouds of pathogenic microbes could in theory kill or incapacitate unprotected populations over very large areas. Such weapons were never used. (Ma.Me./J.P.P.R.)

Fortification

Fortifications are military positions that have been strengthened against attack. They are usually of two types: permanent and field. Permanent fortifications include elaborate forts and troop shelters; they are most often erected in times of peace or upon threat of war. Field fortifications are constructed when in contact with an enemy or when contact is imminent. They consist of entrenched positions for personnel and crew-served weapons, cleared fields of fire, and obstacles such as explosive mines, barbed-wire entanglements, felled trees, and antitank ditches. Both field and permanent fortifications often take advantage of natural obstacles, such as canals and rivers, and they are usually camouflaged or otherwise concealed. Both types are designed to assist the defender to obtain the greatest advantage from his own strength and weapons while preventing the enemy from using his resources to best advantage.

This section discusses military fortification since the introduction of rifled artillery and small arms. For discussions of fortification up to the modern era, see above *Military technology before the modern era: Antiquity and the classical age; The age of cavalry;* and *The gunpowder revolution.*

TRENCH WARFARE, 1860–1918

The American Civil War. In the American Civil War, field fortifications emerged as an essential of warfare, with both armies employing entrenchments to an extent never before seen. Troops learned to fortify newly won positions immediately; employing spades and axes carried in their packs, they first dug rifle pits and then expanded them into trenches. Early in the war, General Robert E. Lee *The adopted the frontier rifleman's breastwork composed of rifleman's two logs on the parapet of the entrenchment, and many breastwork of Lee's victories were the result of his ability to use hasty entrenchments as a base for aggressive employment of fire and maneuver. Two notable sieges, that of Vicksburg, Miss., in the west, and Petersburg, Va., in the east, were characterized by the construction of extensive and continuous trench lines that foreshadowed those of World War I. In the Cold Harbor, Va., campaign, when General Ulysses S. Grant sent his troops against Confederate earthworks, he lost 14,000 men in 13 days. Field mines and booby traps were used extensively, and trench mortars were developed to lob shells into opposing trenches.

World War I. The lesson taught by accurate, long-range fire from entrenched positions in the American Civil War was lost on European commanders. Even the bitter experiences of appalling losses in the Crimean, Franco-German, and Boer wars failed to lessen an ardour for the theory of the offensive that was so fervent as to leave little concern for defensive tactics in the field. Few took notice of the immense casualties the Turks inflicted from behind

field fortifications in the Russo-Turkish War of 1877–78, and even though the Russo-Japanese War soon after the turn of the century underscored the lethal power of the machine gun and breech-loading rifled artillery, most European commanders saw the increased firepower as more a boon to the offensive than to the defensive.

The fallacy of the faith in offensive firepower was soon convincingly demonstrated. Once the French had checked the German right wing at the Marne River, the fighting degenerated into what was in effect a massive siege. For 600 miles (1,000 kilometres), from Switzerland to the North Sea, the landscape was soon scarred with opposing systems of zigzag, timber-revetted, sandbag-reinforced trenches, fronted by tangles of barbed wire sometimes more than 150 feet (45 metres) deep and featured here and there by covered dugouts providing shelter for troops and horses and by observation posts in log bunkers or concrete turrets. The trench systems consisted of several lines in depth, so that if the first line was penetrated, the assailants were little better off. Rail and motor transport could rush fresh reserves forward to seal off a gap faster than the attackers could continue forward. Out beyond the trenches and the barbed wire was a muddy, virtually impassable desert called no-man's-land, where artillery fire soon eliminated habitation and vegetation alike. The fighting involved masses of men, masses of artillery, and masses of casualties. Toxic gases—asphyxiating, lachrymatory, and vesicant—were introduced in a vain effort to break the dominance of the defense, which was so overpowering that for more than two years the opposing lines varied less than 10 miles in either direction.

During the winter of 1916–17, the Germans prepared a reserve trench system, the Hindenburg Line, containing deep dugouts where the men could take cover against artillery fire and machine guns emplaced in concrete shelters called pillboxes. Approximately two miles behind the forward line was a second position, almost as strong. The Hindenburg Line resisted all Allied assaults in 1917, including a vast British mining operation under the Messines Ridge in Belgium that literally blew up the ridge, inflicting 17,000 casualties at one blow; the advance failed to carry beyond the ridge.

The Hindenburg Line (margin note)

PERMANENT FORTIFICATION, 1914–45

World War I. Most defensive thinking on the eve of World War I was reserved for the permanent fort, which was designed to canalize enemy advance and to afford time for national mobilization. The leading fortification engineer of the time was a Belgian, Henri Brialmont. He placed his forts, built of concrete, at an average distance of four miles from a city, as with 12 forts at Liège, and at intervals of approximately 2.5 miles. At Antwerp his defense system was even more dense. He protected the big guns of his forts with turrets· of steel and developed disappearing cupolas. Some forts were pentagonal, others triangular, with much of the construction underground.

In building defenses along the frontier facing Germany, French engineers emulated Brialmont, with particularly strong clusters of fortresses at Verdun and Belfort. So monstrous were the forts of the time that they were known as "land battleships." But by marching through Belgium with a strong right wing (the Schlieffen plan), the Germans circumvented the powerful French fortresses. Passing between the forts at Liège, which Brialmont had intended to be connected with trenches, they took the city in only three days, then systematically reduced the forts. Namur, also heavily fortified, resisted the powerful Big Bertha guns for only four days. The concrete of the Belgian fortifications crumbled under the pounding, but the French forts at Verdun, of more recent and sturdier construction, later absorbed tremendous punishment and served as focal points for some of the war's bloodiest fighting.

Linear fortifications of World War II. *The Maginot Line and the West Wall.* In the interval between world wars, several European countries built elaborate permanent fortifications. The largest was the French Maginot Line, a system of mammoth, self-contained forts stretching from Switzerland to the vicinity of the Belgian frontier near Montmédy. The reinforced concrete of the forts was thicker than any theretofore used, the disappearing guns bigger and more heavily armoured. Ditches, embedded steel beams, and minefields guarded against tank attack. A large part of the works were completely underground. Outposts were connected to the main forts by concrete tunnels. But, because French and British military leaders were convinced that if war came again with Germany the Allies would fight in Belgium, the French failed to extend the line to the sea, relying instead on an outmoded system of unconnected fortresses left over from before World War I. It was this weakness that the Germans subsequently exploited in executing a modified version of the Schlieffen plan, cutting in behind the permanent defenses and defeating France without having to come to grips with the Maginot Line.

The Germans confronted that portion of the Maginot Line facing the Saar River with fortifications of their own, the West Wall. Later extended northward to the Dutch frontier and southward along the Rhine to Switzerland, the West Wall was not a thin line of big forts but a deep band, up to five miles thick, of more than 3,000 small, mutually supporting pillboxes, observation posts, and troop shelters. For passive antitank defense the line depended upon natural obstacles, such as rivers and lakes, and upon "dragon's teeth," five rows of pyramid-shaped reinforced concrete projections.

Pillboxes and tank obstacles (margin note)

The Germans did not rely on the West Wall to halt an attack but merely to delay it until counterattacks by mobile reserves could eliminate any penetration. The value of their concept remains undetermined; the line was not attacked until late 1944, after the German armies had incurred severe defeats and lacked adequate reserves. The West Wall nevertheless forced Allied troops into costly attacks to eliminate it.

Other fort series. Elsewhere in World War II many fortifications similar to these two basic types were built. The Italians constructed a series of new fortifications and modernized existing World War I defenses along the country's mountainous northern and northeastern frontiers; the Finns maintained a World War I defense facing the Soviet Union, the Mannerheim Line (named after a Finnish marshal and statesman); the Soviets built the Stalin Line facing Poland; the Czechoslovaks constructed what became known as the Little Maginot Line to oppose Germany; the Greeks built the Metaxas Line facing Bulgaria; and the Belgians erected a series of elaborate forts along the Albert Canal. German capture of the most elaborate and allegedly impregnable of the Belgian forts, Eben Emael, in a matter of hours in the first two days of the campaign against France and the Low Countries in 1940 startled the world. Arriving silently on the night of May 10 in gliders, troops landed atop the fort and began systematically to destroy turrets and casemates. Soon after daylight they were joined by 300 men arriving by parachute. Around noon of May 11 the 1,000-man garrison surrendered.

Despite at least comparable surprise and the same so-called blitzkrieg methods, the Germans required more time to penetrate the more dispersed forts of the Stalin Line in the Soviet Union. The delay gained two months of invaluable time for the Soviet troops, without which they might well have been unable to stop the Germans at the gates of Moscow.

German channel defenses. The Germans employed Fritz Todt, the engineer who had designed the West Wall, and thousands of impressed labourers to construct permanent fortifications along the Belgian and French coasts facing the English Channel; this was the Atlantic Wall. The line consisted primarily of pillboxes and gun emplacements embedded in cliffsides or placed on the waterfronts of seaside resorts and ports. Included were massive blockhouses with disappearing guns, newsreels of which the Germans sent out through neutral sources in an effort to awe their adversaries, but the numbers of big blockhouses actually were few. Behind the line, in likely landing spots for gliders and parachutists, the Germans emplaced slanted poles, which the troops called *Rommelsspargel* (Rommel's asparagus), after their commander Field Marshal Erwin Rommel. Embedded in the sand of the beaches below the high-tide mark were numerous obstacles, varying in shape

Obstacles to air and amphibious assault (margin note)

and depth, some topped with mines. Barbed wire and antitank and antipersonnel mines interlaced the whole. On the French southwestern and southern coasts similar, though less formidable, defenses were erected.

When the Allies landed in force on the Cotentin Peninsula of Normandy on D-Day—June 6, 1944—they found the defenses far less formidable than they had anticipated. This was attributable to a number of reasons. The Germans had constructed the strongest defenses in the Pas-de-Calais region facing the narrowest part of the English Channel and had stationed their most battleworthy troops there; demands of other fighting fronts had siphoned many of the best German troops from France; the Germans lacked air and naval support; Allied airpower was so strong that movement of German reserves was seriously impeded; landings of Allied airborne troops behind the beaches spread confusion in German ranks; and the Germans were deluded into believing the invasion was a diversion, that a second and larger invasion was to follow in the Pas-de-Calais. Only at one of the two American beaches, given the code name Omaha, was the success of the landing ever in doubt, partly because of rough seas, partly because of the chance presence of an elite German division, and partly because of the presence of high bluffs. Paradoxically, the Allies had less difficulty with the highly publicized beach defenses than they had later with field fortifications based on the Norman hedgerows, earthen embankments several feet thick and five feet high that local farmers through the centuries had erected around thousands of irregularly shaped little fields to fence their cattle and protect their crops from strong ocean winds.

NUCLEAR FORTIFICATION

At the close of World War II most military theorists considered that permanent fortifications of the type previously employed were economically impracticable in view of their vulnerability to the incredible power of nuclear explosives and the methods, such as vertical envelopment from the air, that might be employed to reduce them. Important exceptions to this generalization were the reinforced concrete and deep tunnels used to protect strategic-missile launch facilities. The United States, the former Soviet Union, and (to a lesser degree) France, Great Britain, Israel, and China invested heavily in such defensive works. Probably the most important and most characteristic of these works was the missile silo, a tubular structure of heavily reinforced concrete sunk into the ground to serve as a protective installation and launch facility for a single intercontinental ballistic missile (ICBM). These silos were "hardened" to resist a calculated amount of blast and shock from a nuclear detonation. Launch crews were protected in similarly constructed underground bunkers nearby. Elaborate calculations on the number of ICBM warheads needed to destroy a hardened silo with a given degree of certainty became an integral part of the strategic calculus in the 1960s. In this way, permanent fortifications resumed their previous place of importance in strategic calculations.

Of particular concern to strategists of the United States and the Soviet Union was the vulnerability of land-based ICBMs to preemptive nuclear attack. Elaborate defensive works were proposed to protect them. One basing scheme involved a network of fortified missile shelters connected by roads or railroad tracks. Huge, closed missile transporters would shuttle the missiles from one shelter to another in such a manner that the enemy would not know which shelters were occupied and which were empty. An even more extreme plan for protecting the U.S. land-based ICBM force was designed around fratricide, the theory that multiple nuclear explosions cannot occur at the same time in close proximity to one another because the first detonated warhead triggers low-yield partial explosions in the others. The proposal, called dense pack, would exploit this phenomenon by packing a large number of super-hardened ICBM silos closely together in a single location.

Other permanent fortifications of the nuclear age were designed as headquarters sites or command and control installations. For example, a joint U.S.-Canadian project, the North American Air Defense Command (Norad), included a series of radar posts across northern Canada and Alaska to provide early warning of the approach of hostile bombers or missiles. The system and the aircraft and missiles supporting it were controlled from a vast underground complex embedded in the rock of Cheyenne Mountain near Colorado Springs, Colo.

(W.H.B./C.B.MacD./J.F.G.)

Tanks and armoured vehicles

Tanks are heavily armed and armoured combat vehicles that move on two endless metal chains called tracks. They are the principal type of armoured vehicle. Other major types include tracked and wheeled infantry carriers, which were conceived only for transporting troops into action but which also have been used to some extent for fighting; armoured cars, which often resemble the lighter types of tanks but run on wheels; self-propelled guns, some of which are only partly armoured or wheeled; and such specialized vehicles as armoured recovery vehicles, armoured bulldozers, and amphibious landing vehicles.

TANKS

Tanks are essentially tracked, protected weapon platforms that make the weapons mounted in them more effective by their cross-country mobility and by the protection they provide for their crews. Weapons mounted in tanks have ranged from single rifle-calibre machine guns to, in recent years, long-barreled guns of 120- or 125-millimetre (4.72- or 4.92-inch) calibre.

Earliest developments. The use of vehicles for fighting dates to the 2nd millennium BC, when horse-drawn war chariots were used in the Middle East by the Egyptians, Hittites, and others as mobile platforms for combat with bows and arrows. The concept of protected vehicles can be traced back through the wheeled siege towers and battering rams of the Middle Ages to similar devices used by the Assyrians in the 9th century BC. The two ideas began to merge in the battle cars proposed in 1335 by Guido da Vigevano, in 1484 by Leonardo da Vinci, and by others, down to James Cowen, who took out a patent in England in 1855 for an armed, wheeled, armoured vehicle based on the steam tractor.

But it was only at the beginning of the 20th century that armoured fighting vehicles began to take practical form. By then the basis for them had become available with the appearance of the traction engine and the automobile. Thus, the first self-propelled armoured vehicle was built in 1900 in England when John Fowler & Company armoured one of their steam traction engines for hauling supplies in the South African (Boer) War (1899–1902). The first motor vehicle used as a weapon carrier was a powered quadricycle on which F.R. Simms mounted a machine gun in 1899 in England. The inevitable next step was a vehicle that was both armed and armoured. Such a vehicle was constructed to the order of Vickers, Son and Maxim Ltd. and was exhibited in London in 1902. Two years later a fully armoured car with a turret was built in France by the Société Charron, Girardot et Voigt, and another was built concurrently in Austria by the Austro-Daimler Company.

To complete the evolution of the basic elements of the modern armoured fighting vehicle, it remained only to adopt tracks as an alternative to wheels. This became inevitable with the appearance of the tracked agricultural tractor, but there was no incentive for this until after the outbreak of World War I. A tracked armoured vehicle was proposed in France as early as 1903 but failed to arouse the interest of military authorities, as did a similar proposal made in England in 1908. Three years later a design for a tracked armoured vehicle was rejected by the Austro-Hungarian and then by the German general staffs, and in 1912 the British War Office turned down yet another design.

World War I. The outbreak of World War I in 1914 radically changed the situation. Its opening stage of mobile warfare accelerated the development of armoured cars, numbers of which were quickly improvised in Belgium, France, and Britain. The ensuing trench warfare,

The missile silo

Early armoured fighting vehicles

which ended the usefulness of armoured cars, brought forth new proposals for tracked armoured vehicles. Most of these resulted from attempts to make armoured cars capable of moving off roads, over broken ground, and through barbed wire. The first tracked armoured vehicle was improvised in July 1915, in Britain, by mounting an armoured car body on a Killen-Strait tractor. The vehicle was constructed by the Armoured Car Division of the Royal Naval Air Service, whose ideas, backed by the First Lord of the Admiralty, Winston S. Churchill, resulted in the formation of an Admiralty Landships Committee. A series of experiments by this committee led in September 1915 to the construction of the first tank, called "Little Willie." A second model, called "Big Willie," quickly followed. Designed to cross wide trenches, it was accepted by the British Army, which ordered 100 tanks of this type (called Mark I) in February 1916 (see Figure 23).

Simultaneously but independently, tanks were also developed in France. Like the very first British tank, the first French tank (the Schneider) amounted to an armoured box on a tractor chassis; 400 were ordered in February 1916. But French tanks were not used until April 1917, whereas British tanks were first sent into action on Sept. 15, 1916. Only 49 were available, and their success was limited, but on Nov. 20, 1917, 474 British tanks were concentrated at the Battle of Cambrai and achieved a spectacular breakthrough. These tanks, however, were too slow and had too short an operating range to exploit the breakthrough. In consequence, demand grew for a lighter, faster type of tank, and in 1918 the 14-ton Medium A appeared with a speed of eight miles (13 kilometres) per hour and a range of 80 miles. After 1918, however, the most widely used tank was the French Renault F.T., a light six-ton vehicle designed for close infantry support (see Figure 23).

When World War I ended in 1918, France had produced 3,870 tanks, and Britain 2,636. Most French tanks survived into the postwar period; these were the Renault F.T., much more serviceable than their heavier British counterparts. Moreover, the Renault F.T. fitted well with traditional ideas about the primacy of the infantry, and the French army adopted the doctrine that tanks were a mere auxiliary to infantry. France's lead was followed in most other countries; the United States and Italy both assigned tanks to infantry support and copied the Renault F.T. The U.S. copy was the M1917 light tank, and the Italian the Fiat 3000. The only other country to produce tanks by the end of the war was Germany, which built about 20.

Interwar developments. The Renault F.T. remained the most numerous tank in the world into the early 1930s. Aware of the need for more powerful vehicles, if only for leading infantry assaults, the French army took the lead in developing well-armed tanks. The original 1918

French Schneider and St. Chamond tanks already had 75-millimetre guns while the heavier British tanks were at best armed with 57-millimetre guns. After the war the French built 10 68-ton 2C tanks with the first turret-mounted 75-millimetre guns and continued to develop 75-millimetre-gun tanks, notably the 30-ton Char B of 1936.

In the meantime, Britain took the lead, technically and tactically, in developing the mobility of tanks. Even before World War I had ended, work had started on the Medium D with a maximum speed of 20 miles per hour. Between 1923 and 1928 the British army ordered 160 of the new Vickers Medium tanks. They were virtually the only tanks the British army had until the early 1930s and the only tanks to be produced in quantity anywhere in the world during the mid-1920s. The Vickers Mediums stimulated the Royal Tank Corps to develop mobile tactics, and various experiments during the 1920s and early '30s resulted in the general adoption of two categories of tanks. Mobile tanks were intended for the role performed earlier by horse cavalry, while slower but more heavily armoured tanks provided infantry support.

Before this division into mobile and slow tanks had crystallized, several different designs were tried. The British Independent tank of 1925, with five turrets, started a trend toward multiturreted heavy tanks. Another trend setter was a small turretless tankette, originated in Britain by Major Giffard le Quesne Martel and John Carden in the mid-1920s, and a slightly heavier, turreted two-man light tank. The number of light tanks grew rapidly after 1929, as several countries started to produce armoured vehicles. The Soviet Union was by far the most important producer; on a much smaller scale Poland, Czechoslovakia, and Japan entered the field in 1930–31. Concurrently, tank production started up again in France and Italy. As tank production grew and spread among nations, the value of light tanks armed only with machine guns decreased, and heavier models armed with 37- to 47-millimetre guns for fighting other tanks began to displace them. An early example was the Vickers-Armstrong six-ton model of 1930, copied on a large scale in the Soviet Union (as the T-26). The most successful example was the BT, also built in large numbers in the Soviet Union. The fastest tank of its day, the BT was based on designs evolved in the United States by J.W. Christie, who in 1928 built an experimental model capable of 42.5 miles per hour. Christie's vehicles could run on wheels after the removal of tracks and, far more significant, had road wheels independently suspended. This enabled them to move over broken ground faster than tanks with the earlier types of suspension.

Although they were relatively well armed and mobile, tanks of the T-26 and BT type were lightly armoured (plates 10 to 15 millimetres thick) and were not, therefore, suitable for close infantry support. This was clearly

Figure 23: *Tanks of World War I.*

(Left margin notes)
First tracked armoured vehicle

Light infantry-support tanks

demonstrated in 1937 during the Civil War in Spain, where T-26 and BT tanks were used by the Republican forces. Even before this time, it had become clear that tanks that moved at the slow pace of the infantry and were therefore exposed to the full effect of antitank guns had to be thickly armoured. This realization led in the mid-1930s to such infantry tanks as the French R-35 with 40-millimetre and the British A.11 with up to 60-millimetre armour.

Heavily armed tank-fighting tanks

Apart from being lightly armoured, the Soviet BT, the equivalent British cruiser tanks, and the German Pz. III also required support from more heavily armed tanks if they were to engage in fighting of any intensity. The need for tanks with more powerful 75-millimetre guns was clearly recognized in Germany, leading in 1934 to the design of the Pz. IV. The problem was realized less clearly in the Soviet Union, even though the T-28 and T-35 multiturret tanks with 76-millimetre guns were first built there in 1932–33. But the Russians recognized more quickly than others the need for the next step, which was to replace all the light-medium tanks armed with 37- to 47-millimetre guns by medium tanks armed with 75- or 76-millimetre guns. Thus, in 1939, while the Germans were still developing the Pz. III from a 37-millimetre to a 50-millimetre version, the Russians were already concentrating on the T-34 medium tank with a 76-millimetre gun.

Other armies were farther behind in producing well-armed tanks on the eve of World War II. All but 80 of the 1,148 tanks that Britain had produced between 1930 and 1939 were still armed only with machine guns. Italy was even worse off, with only 70 M/11 tanks with 37-millimetre guns while the rest of its total of 1,500 were small, machine-gun-armed tankettes. The United States had only about 300 machine-gun-armed light tanks. Most of the 2,000 tanks produced in Japan were equally lightly armed. By comparison, France had a more powerful tank force—2,677 modern tanks, of which, however, only 172 were the Char B, armed with 75-millimetre guns. The largest force was the Soviet Union's, which, as a result of a massive production program, started in 1930–31, had about 20,000 tanks by 1939, considerably more than the rest of the world put together.

World War II. The most effective tank force proved to be the German, composed in 1939 of 3,195 vehicles, including 211 Pz. IVs (see Figure 24). What made the German tanks so formidable was that instead of being divided between various infantry and cavalry tank units they were all concentrated and used in massed formations in the panzer divisions. The successes of the panzer divisions during the first two years of World War II led the major armies to reorganize most of their tanks into similar formations; this resulted in a dramatic increase in production.

The campaigns of 1939–41, in which armoured forces played such an important role, also intensified the technical development of tanks and other armoured vehicles. The German Pz. IV and Soviet T-34 were rearmed in 1942 with longer-barreled, higher-velocity guns; soon afterward these began to be displaced by more powerfully armed tanks. In 1943 the Germans introduced the Panther medium tank with a long 75-millimetre gun having a muzzle velocity of 3,070 feet (936 metres) per second, compared with 1,260 feet per second for the original Pz. IV and 2,460 feet per second for its 1942 version. The 43-ton Panther weighed almost twice as much as its predecessor and was correspondingly better armoured. Germany also introduced the still more powerful Tiger tank, armed with an 88-millimetre gun. Its final version (Tiger II), at 68 tons, was to be the heaviest tank used during World War II. To oppose it, the Russians brought out the JS, or Stalin, heavy tank, which appeared in 1944 armed with a 122-millimetre gun. Its muzzle velocity was lower than that of the German 88-millimetre guns, however, and it weighed only 46 tons. At about the same time the T-34 was rearmed with an 85-millimetre gun.

German Panther and Tiger tanks

In contrast to the breakthrough role of the earlier heavy tanks, the Tiger and JS tanks functioned chiefly to support basic medium tanks by destroying enemy tanks at long range. German and Soviet armies also developed other heavy vehicles for this purpose, such as the 128-millimetre-gun Jagdtiger and the 122-millimetre-gun ISU, which, in effect, were turretless tanks. In addition, all armies developed lightly armoured self-propelled antitank guns. The U.S. Army developed a specialized category of tank destroyers that resembled self-propelled guns in being relatively lightly armoured but that, like tanks, had rotating turrets.

The turretless-tank type of vehicle originated with the Sturmgeschutz, or assault gun, introduced by the German army for infantry support but subsequently transformed into more versatile vehicles particularly suited for destroying enemy tanks. No such vehicles were produced in Britain or the United States. Throughout the war, however, the British army retained a specialized category of infantry tanks, such as the Churchill, and of cruiser tanks, such as the Crusader and Cromwell. The former were well-armoured, and the latter were fast, but none was well-armed compared to German and Soviet tanks. As a result, during 1943 and 1944, British armoured divisions were mostly equipped with U.S.-built M4 Sherman medium tanks. The M4 was preceded by the mechanically similar M3 medium, which was also armed with a medium-velocity 75-millimetre gun but mounted it in the hull instead of the turret, because this could be put into production more quickly when tanks were urgently required in 1940 and 1941. Production of the M4 began in 1942, and eventually 49,234 were built, making it the principal tank of U.S. and other allied armoured forces. Successful when first introduced, it was by 1944 no longer adequately armed and should have been replaced by a new medium tank. But the U.S. Army, like the British, adhered to the fallacious doctrine that armoured divisions should confine themselves to exploitation of infantry breakthroughs and did not, therefore, need powerfully armed tanks. Only

toward the end of the war did the U.S. Army introduce a few M26 Pershing heavy tanks with a 90-millimetre gun comparable to that of the original German Tiger (see Figure 24). Similarly, the British army introduced the prototypes of the Centurion tank with a 76-millimetre gun comparable to that of the German Panther. Otherwise, U.S. and British tanks were well behind the German and Soviet tanks in their gun power.

Postwar tank design. After World War II it was generally recognized that all tanks must be well-armed to fight enemy tanks. This finally ended the division of tanks into under-gunned categories of specialized infantry and cavalry tanks, which the British army retained longer than any other. Still not fully recognized, however, were the advantages of concentrating tanks in fully mechanized formations, and the British and U.S. armies continued to divide tanks between the armoured divisions and the less mobile infantry divisions. After World War II, tanks also suffered from one of the periodic waves of pessimism about their future. New antitank weapons, such as rocket launchers and recoilless rifles, and the mistaken belief that the value of tanks lay primarily in their armour protection, caused this attitude. The Soviet army, however, maintained large armoured forces, and the threat they posed to western Europe as the Cold War became more intense, together with the havoc created by Soviet-built T-34/85 tanks during the North Korean invasion of South Korea in 1950, provided a new impetus to development.

The development of tactical nuclear weapons in the mid-1950s provided further stimulus to the development of tanks and other armoured vehicles. Nuclear weapons encouraged the use of armoured forces because of the latter's mobility and high combat power in relation to their vulnerable manpower. Moreover, armoured vehicles proved capable of operating in relative proximity to nuclear explosions by virtue of their protection against blast and radioactivity.

As less emphasis was placed after a time on nuclear weapons and more on conventional forces, tanks retained their importance. This was based on their being recognized, particularly from the early 1970s, as the most effective counter to other armoured forces, which formed the principal threat posed on the ground by potential aggressors.

Armament. In keeping with the importance attached to the ability of tanks to defeat enemy tanks, great emphasis was placed after World War II on their armament. The result was progressive increases in the calibre of tank guns, the development of new types of ammunition with greater armour-piercing capabilities, and the introduction of more sophisticated fire-control systems to improve tank guns' ability to hit targets.

Increases in gun calibre are well illustrated by the British Centurion, which started in 1945 with a 76-millimetre gun but in 1948 was rearmed with an 83.8-millimetre gun and in 1959 with an even more powerful 105-millimetre gun. Moreover, during the 1950s the capabilities of British tank units were augmented by a small number of Conqueror heavy tanks armed with 120-millimetre guns, and in the early 1970s the Centurions were entirely replaced by Chieftains armed with a new and more effective 120-millimetre gun.

Similar increases took place in the calibre of Soviet tank guns. After World War II the basic T-34/85 tanks armed with 85-millimetre guns were replaced by T-54 and T-55 tanks armed with 100-millimetre guns. They were followed in the 1960s by the T-62, with a 115-millimetre gun, and in the 1970s and '80s by the T-64, T-72, and T-80, all with 125-millimetre smoothbore guns. The JS-3 and T-10 heavy tanks with their less powerful 122-millimetre guns had by then been withdrawn. This left the Soviet army in the same position as others of having a single type of battle tank as well armed as contemporary technology would allow (see Figure 25).

For a time the U.S. Army also subscribed to a policy of developing heavy as well as medium tanks. But the heavy M103 tank, armed with a 120-millimetre gun, was only built in small numbers in the early 1950s. As a result, virtually the only battle tanks the U.S. Army had were the M46, M47, and M48 medium tanks, all armed with 90-millimetre guns. After the mid-1950s the M47 tanks were passed on to the French, Italian, Belgian, West German, Greek, Spanish, and Turkish armies, and during the 1960s the M48 began to be replaced by the M60, which was armed with a U.S.-made version of the 105-millimetre gun developed for the British Centurion.

The same 105-millimetre gun was adopted for the Pz. 61 and Pz. 68 tanks produced in Switzerland, the West German Leopard 1, the Swedish S-tank, the Japanese Type 74, and the Mark 1 and 2 versions of the Israeli Merkava. It was also retained in the original version of the U.S. M1 tank developed in the 1970s, but the subsequent M1A1 version of the 1980s was rearmed with a 120-millimetre gun originally developed in West Germany for the Leopard 2 tank (see Figure 25). The British Challenger, introduced in the 1980s, was also armed with 120-millimetre guns, but these were still of the rifled type.

The last years of World War II saw the development of more effective antitank ammunition with armour-piercing, discarding-sabot (APDS) projectiles. These had a smaller-calibre, hard tungsten carbide core inside a light casing. The casing fell away on leaving the gun barrel, while the core flew on at an extremely high velocity. The APDS, which was adopted for the 83.8-millimetre gun of the Centurions, was fired with a velocity of 4,692 feet per second. By comparison, earlier full-calibre, armour-piercing projectiles had a maximum muzzle velocity of about 3,000 feet per second. With this shell the Centurion's 83.8-millimetre gun could penetrate armour twice as thick as could the 88-millimetre gun of the German Tiger II of World War II. *(margin note: Armour-piercing ammunition)*

An alternative type of armour-piercing ammunition developed during the 1950s was the high-explosive antitank (HEAT) shell. This shell used a shaped charge with a conical cavity that concentrated its explosive energy into a very-high-velocity jet capable of piercing thick armour. The HEAT round was favoured by the U.S. Army for its 90-millimetre tank guns and also by the French army for the 105-millimetre gun of its AMX-30 tank, introduced in the mid-1960s. However, during the 1970s both APDS and HEAT began to be superseded by armour-piercing, fin-stabilized, discarding-sabot (APFSDS) ammunition. These projectiles had long-rod penetrator cores of tungsten alloy or depleted uranium; they could be fired with muzzle velocities of 5,400 feet per second or more, making them capable of perforating much thicker armour than all earlier types of ammunition.

During the 1960s, attempts were made to arm tanks with guided-missile launchers. These were to provide tanks with a combination of the armour-piercing capabilities of large shaped-charge warheads with the high accuracy at long range of guided missiles. The U.S. M60A2 and the U.S.-West German MBT-70 were armed with 152-millimetre gun/launchers firing Shillelagh guided antitank missiles, and the AMX-30 was armed experimentally with the 142-millimetre ACRA gun/launcher. But the high cost, unreliability, and slow rate of fire of the missiles, together with the appearance of APFSDS ammunition and greatly improved fire-control systems, led to abandonment of gun/launchers in the early 1970s.

The first major postwar advance in fire-control systems was the adoption of optical range finders, first on the M47 tank and then on the Leopard 1, the AMX-30, and other tanks. In the 1960s, optical range finders began to be replaced by laser range finders. In combination with electronic ballistic computers, these greatly increased the hit probability of tank guns. They became standard in all new tanks built from the early 1970s and were retrofitted in many of the earlier tanks.

Another major development was that of night sights, which enabled tanks to fight in the dark as well as in daylight. Originally of the active infrared type, they were first adopted on a large scale on Soviet tanks. Other tanks were fitted from the 1960s with image-intensifier sights and from the 1970s with thermal imaging sights. These latter were called passive because, unlike active infrared systems, they did not emit energy and were not detectable. *(margin note: Infrared night sights)*

After World War II an increasing number of tanks were fitted with stabilized gun controls to enable them to fire

more accurately on the move (*i.e.*, to keep their gun barrels at a constant angle of elevation even while the tank was riding over bumps or depressions). At first some tanks, such as the T-54, had their guns stabilized only in elevation, but the Centurion already had stabilization in traverse as well as elevation, and this became standard beginning in the 1970s. Afterward, tanks were also provided with independently stabilized gunners', as well as commanders', sights, the better to engage targets on the move.

Armour. Until the 1960s, tank armour consisted of homogeneous steel plates or castings. The thickness of this armour varied from eight millimetres on early tanks to 250 millimetres at the front of the German Jagdtiger of

Figure 25: *Modern heavy battle tanks.*
(Top) Soviet T-72, with 125-millimetre gun. A snorkel is mounted for submerged fording. (Middle) West German Leopard 2, with 120-millimetre gun. Smoke dischargers are fitted onto the side of the turret for concealment. (Bottom) U.S. M1A1, with 120-millimetre gun adapted from the Leopard 2. The M1A1 is powered by a gas turbine engine.

1945. After World War II, opinions differed about the value of armour protection. Tanks such as the Leopard 1 and AMX-30 had relatively thin armour for the sake of light weight and greater mobility, which was considered to provide a greater chance of battlefield survival. Other tanks, such as the Chieftain, had heavier armour, up to 120 millimetres thick at the front, and the Arab-Israeli Wars of 1967 and 1973 demonstrated the continued value of heavy armour.

At the same time, new types of armour were developed that were much more effective than homogeneous steel, particularly against shaped-charge warheads. The new types were multilayered and incorporated ceramics or other nonmetallic materials as well as steel. The first was successfully developed in Britain under the name of Chobham armour. Armour of its kind was first adopted in the early 1970s in the M1 and Leopard 2; it then came into general use in place of simple steel armour.

Fighting in Lebanon in 1982 saw the first use, on Israeli tanks, of explosive reactive armour, which consisted of a layer of explosive sandwiched between two relatively thin steel plates. Designed to explode outward and thus neutralize the explosive penetration of a shaped-charge warhead, reactive armour augmented any protection already provided by steel or composite armour. *Reactive armour*

The increased protection afforded to tanks inevitably increased their weight. Some tanks introduced during the 1950s and '60s, such as the T-54 and AMX-30, weighed only 36 tons, but the Chieftain already weighed 54 tons. Most tanks introduced during the 1980s, such as the M1 and the Leopard 2, also weighed more than 50 tons, and the Challenger weighed as much as 62 tons.

Mobility. In spite of the progressive increases in weight, tanks' speed and agility actually increased because they were provided with more powerful engines. After World War II, tank engines had an output of 500 to 800 horsepower, but, starting with the MBT-70, their output increased to 1,500 horsepower. Engines of this power were installed in the M1 and the Leopard 2, giving them power-to-weight ratios of more than 20 horsepower per ton.

Most tank engines of the immediate postwar years had 12 cylinders in a V-configuration and at first were of the spark-ignition gasoline type. But Soviet tanks already had diesel engines, and from the 1960s almost all tanks were diesel-powered. This increased their range of operation because of the greater thermal efficiency of the diesels, and it reduced the risk of catastrophic fires that could erupt if the armour was perforated by enemy weapons.

The development of gas turbines led in the 1960s to the use of one, in combination with a diesel engine, in the Swedish S-tank. After that, a 1,500-horsepower gas turbine was adopted to power by itself the M1 and M1A1. A gas turbine also powered the Soviet T-80, introduced in the 1980s. All other new tanks of the 1980s continued to be powered by diesels because of their greater fuel economy.

Since the speed of tanks over rough ground depended not only on the power of their engines but also on the effectiveness of their suspensions, the latter developed considerably in the postwar era. Almost all tanks adopted independently located road wheels, sprung in most cases by transversely located torsion bars. Exceptions to this were the Centurion and Chieftain and the Merkava, which used coil springs. To improve their ride over rough ground still further, most tanks built during the 1980s were fitted with hydropneumatic instead of metallic spring units.

Configuration. The great majority of postwar tanks continued the traditional configuration of driver's station at the front of the hull, engine compartment at the rear, and rotating turret at the centre. The turret mounted the main armament and was occupied by the tank's commander, gunner, and loader. This configuration, introduced by the Vickers-Armstrong A.10 tank designed in 1934, became almost universal after World War II, but after 1960 it was abandoned in some cases in favour of novel configurations. One widely adopted configuration retained the turret but replaced the human loader by an automatic loading mechanism. The first examples of this were on the T-64 and T-72 tanks, whose guns were automatically loaded from a carousel-type magazine below the turret. *Automatic loading*

Another tank with an unconventional configuration was the Merkava, which had its engine compartment at the front and the ammunition at the rear of the hull, where it was least likely to be hit by enemy fire. The Merkava also had a turret with a low frontal area, which reduced the target it presented to enemy weapons.

AMPHIBIOUS VEHICLES

The need to cross rivers and other water obstacles led to the development of amphibious tanks, beginning with the British Medium D, designed in 1918. Amphibious tanks built during 1920s and '30s sacrificed armament and armour to achieve low weight in relation to their bulk and, therefore, sufficient buoyancy to float. This confined their usefulness to reconnaissance. A late example of this was the Soviet PT-76, introduced during the 1950s.

After the middle of World War II many other tanks were made amphibious by collapsible flotation screens, which, when erected, allowed even relatively heavy tanks to float. This method was first used with M4 medium tanks during the D-Day landings in Normandy in 1944. Later, flotation screens were permanently installed on the Swedish S-tank, the U.S. M551 Sheridan, and the Scorpion light reconnaissance tank introduced in 1969 by the British army.

An alternative method to crossing rivers was submerged fording, first tried in 1940 with the British A.9 cruiser and the German Pz. III and IV. After World War II, provision for submerged fording was built into several tanks, including the T-54, T-62, and T-72, the Leopard, and the AMX-30.

An entirely different problem was posed by amphibious landings from the open seas; to solve it the U.S. Marine Corps developed the Landing Vehicle Tracked, or LVT. Originally built in 1941 as an unarmoured cargo carrier, the LVT quickly acquired armour. Two types evolved: an armoured amphibious personnel and cargo carrier, and a turreted amphibious gun-vehicle for close fire support during landing operations. Altogether 18,620 LVTs were built during World War II; these played a prominent role in the Pacific campaigns from Guadalcanal onward. After World War II, LVTs were successfully used in Korea, notably for the 1950 Inch'ŏn landing. Two new models were built between 1951 and 1957: an LVTP-5 amphibious carrier, capable of carrying as many as 37 men, and an LVTH-6 armed with a turret-mounted 105-millimetre howitzer. They were followed in the 1970s by the 22.8-ton LVTP-7, which incorporated several improvements, the most important being a boatlike hull with a stern instead of bow loading ramp and two water-jet propulsion units that greatly improved its performance in comparison with that of the earlier LVTs (which were propelled in water as well as on land by means of their tracks). At the same time the LVTP-7 retained the seagoing qualities of the earlier LVTs, which could negotiate rough seas and Pacific surf in contrast to other amphibious vehicles intended primarily for crossing inland water obstacles. The use of water-jet propulsion units in the LVTP-7, however, had been preceded by their use in several amphibious reconnaissance vehicles, including the Soviet PT-76.

The Landing Vehicle Tracked

SELF-PROPELLED GUNS

Self-propelled guns are field artillery, antitank guns, or antiaircraft guns mounted on and fired from tracked or wheeled vehicles. The vehicles are armoured to varying degrees.

The development of self-propelled guns continued after World War II, except for self-propelled antitank guns. These became superfluous when it was recognized that all tanks needed to be sufficiently well-armed to fight enemy tanks. Turretless assault guns, much favoured during World War II by the German and Soviet armies, also virtually disappeared.

The general trend among the remaining self-propelled guns was either toward lightly but completely armoured models with guns mounted in turrets capable of all-around traverse, like most tanks, or toward partially armoured models that were essentially tracked chassis with guns mounted on top. Examples of the completely armoured self-propelled guns were the U.S.-built 155-

millimetre M109 self-propelled howitzer (used not only by the U.S. Army but also by several others), the French 155-millimetre GCT, and the Soviet 122-millimetre SO-122 and 152-millimetre SO-152. Partially armoured models were represented by the U.S.-built M107 175-millimetre gun and M110 8-inch howitzer and by the Soviet 203-millimetre SO-203.

ARMOURED PERSONNEL CARRIERS

After World War II, armoured personnel carriers became the next most important armoured vehicle after battle tanks. Though a few experimental models were built in Britain at the end of World War I, development of armoured carriers did not really begin until they were adopted for the panzer division infantry at the beginning of World War II. Germany's example was quickly followed by the United States, which, by the end of the war, had produced 41,000 carriers. Both the German and U.S. carriers of World War II were of the half-track type and provided only light protection; nevertheless, they represented a major advance on the earlier method of transporting infantry into battle in unarmoured trucks. Moreover, the panzer grenadiers used them effectively as combat vehicles and fought from them on the move, thus greatly increasing the mobility of infantry on the battlefield.

In the postwar era the U.S. Army led in developing fully tracked carriers with all-around armour protection. The first postwar carrier was the large M44. This was followed in 1952 by the M75, which had a similar box body but carried 12 instead of 27 men. A few M75s were used successfully during the Korean War, and it became the first tracked armoured carrier to be used in large numbers.

In 1955 the M75 began to be replaced by the M59, which was similar in appearance but was less expensive and could swim across calm inland waters. In 1960 came the M113, which had a lower silhouette and was considerably lighter, owing partly to the use of aluminum armour (see Figure 26). The M113 was in fact the first aluminum-armoured vehicle to be put into large-scale production. After its appearance, several other armoured carriers, light tanks, and self-propelled guns were built with aluminum armour. Within 30 years more than 76,000 M113 carriers and their derivatives had been produced, making them the most numerous armoured vehicles outside the Soviet bloc. M113 carriers were used extensively in the Vietnam War, often as combat vehicles, although they were not designed for this and were at a disadvantage in spite of the addition of roof-mounted machine guns with shields.

The U.S. M113 armoured personnel carrier

Department of Defense photo

Figure 26: U.S. M113 armoured personnel carrier, capable of carrying 11 infantrymen besides its crew of two.

The first attempt to produce a tracked armoured carrier from which the infantry could fight to some extent was represented by the French AMX-VTT of 1958. A further step in this direction was taken by the West German army with the HS-30, which had a turret with a 20-millimetre cannon. The most significant advance was represented by the Marder, which was produced for the panzer grenadiers of the West German army during the 1970s, and the BMP, mass-produced for the Soviet armoured infantry from the mid-1960s. The Marder weighed 29.2 tons and

carried nine men in addition to mounting a turret with a 20-millimetre cannon. The BMP-1 weighed 13.5 tons and could carry up to 11 men. It was armed with a turret-mounted, low-performance 73-millimetre gun, while the BMP-2 was armed with a high-velocity 30-millimetre cannon; both versions carried externally mounted antitank guided missiles.

Another tracked armoured infantry vehicle was the U.S. M2 Bradley Infantry Fighting Vehicle, introduced in the 1980s. This 10-man vehicle weighed 22.6 tons and had a two-man turret with a 25-millimetre cannon and a TOW antitank missile launcher. Its British equivalent was the Warrior Mechanized Combat Vehicle, produced since 1986. This was also a 10-man vehicle of 24.5 tons with a 30-millimetre cannon in a two-man turret.

In addition to tracked armoured carriers or infantry fighting vehicles, which were intended to cooperate closely with tanks, most armies also developed wheeled armoured carriers for more general use. Examples included the VAB of the French army and the BTR-60, -70, and -80 of the Soviet army.   (R.M.O.)

Naval ships and craft

Naval ships are the chief instruments by which a nation extends its military power onto the seas. Warships protect the movement over water of one's own military forces to coastal areas where they may be landed and used against enemy forces; warships protect one's own merchant shipping against enemy attack; they prevent the enemy from using the sea to transport his own military forces; and they attack the enemy's merchant shipping. Naval ships are also used in blockade—*i.e.,* in attempts to prevent an enemy from importing by sea the commodities necessary for his prosecution of the war. In order to accomplish these objectives, naval ships have been designed from earliest times to be faster and sturdier than merchant ships and to be capable of carrying offensive weapons.

In the modern era the word craft has come to denote small surface vessels that operate usually in coastal waters.

This section traces the development of the major surface warships and craft from their beginnings to the present day. Submarines, which operate below the surface, are discussed separately below. Detailed discussion of weapons used by warships can be found in other sections of this article. For early naval cannon, see *The gunpowder revolution;* for guided antiship and antiaircraft missiles, see *Tactical guided missiles;* for naval airplanes, jets, and helicopters, see *Military aircraft.*

THE AGE OF OAR AND RAM

The first craft fitted purposely to make war were conversions of the dugouts, inflatable bladders, papyrus rafts, or hide boats used in everyday transport. It is probable that the conversion at first consisted simply of a concentration of weapons in the hands of a raiding party. In time conversions added offensive and defensive powers to the craft itself. As vessels became more seaworthy and more numerous, warships designed as such developed both as marauders and as defenses against marauders. The first craft designed and built especially for combat may have sailed in the fleets of Crete and Egypt 5,000 years ago.

Egypt.   The first recorded appearance of warships is on the Nile River, where Egypt's history has centred since antiquity. These boats were built of bundles of reeds lashed together to form a narrow, sharp-ended hull and coated with pitch, and they were hardly suited for tempestuous seas. By 3000 BC larger wooden seagoing versions of the reed craft sailed for distant cruising, trade, and conquest.

Egyptian wooden ships had both oars and sails, being fitted with a bipod (inverted V) mast and a single, large, square sail. The whole mast could be lowered when under oars. Large Egyptian ships had more than 20 oars to a side, with two or more steering oars. The war galley was built to the same pattern but was of stouter construction. Modifications that could be easily incorporated in a merchant ship's hull under construction included elevated decks fore and aft for archers and spearmen, planks fitted to the gunwales to protect the rowers, and a small fighting

(margin note: Merchant galleys modified for war)

top high on the mast to accommodate several archers. Some galleys had a projecting ram, well above the waterline, which may have been designed to crash through the gunwale of a foe, ride up on deck, and swamp or capsize him.

Crete.   By about 2000 BC Crete had evolved into a naval power exercising effective control of the sea in the eastern Mediterranean. Little record exists of Minoan seapower, yet these maritime people may have been the first to build a warship designed as such from the keel up, rather than as a modification of a merchant ship. Thus it was probably the Minoans who began to differentiate between war craft and merchantmen and between the rowing galley and sailing vessel.

Sometime in the 2nd millennium BC the commodious merchantman evolved as a beamy "round ship" powered by sails and emphasizing cargo capacity at the expense of speed. By contrast, the fast fighting "long ship" was narrower, faster, and more agile than the tubby cargo ship. Developing as both predator and protector of maritime trade and coastal cities, it hoisted its sails for cruising but depended on oars when in action.

The Cretan warship had a single mast and a single bank of oars. The sharply pointed or "beaked" bows suggest an emphasis on the tactical use of the ram.

Phoenicia.   Beginning about 1100 BC, the Phoenicians dominated the eastern Mediterranean for about three centuries. Information about Phoenician ships is fragmentary, but they appear to have been built primarily for trading, with a capacity to fight effectively if necessary.

Phoenician trading ships were apparently galleys, mounting a single pole mast with a square sail and with steering oars to port and starboard. Their war galleys show a Cretan influence: low in the bow, high in the stern, and with a heavy pointed ram at or below the waterline. Oars could be carried in a staggered, two-bank arrangement, allowing more oars to be mounted in a ship of a given length and increasing power and momentum. Because the ram was the principal weapon, the vessel's slender build and greater rowing power were important in providing more speed for the decisive shock of battle.

Greece.   Unlike the Egyptians, for whom wood was scarce and costly, the Aegean peoples had an abundance of timber for shipbuilding. The earlier Greek warships were used more to carry attack personnel than as fighting vessels. No mention is made in the *Iliad,* for instance, of sea warfare. Even the pirates of the time were sea raiders seeking their booty ashore rather than in sea actions. The so-called long penteconter, mentioned by Herodotus, was employed in exploring, raiding, and communicating with outlying colonies. Light and fast, with 25 oars to a side, it played an important role in the early spread of Grecian influence throughout the Mediterranean. As the Greek maritime city-states sped the growth of commerce and thus the need for protection at sea, there evolved a galley built primarily for fighting. The first galleys, called uniremes (Latin: *remus,* "oar"), mounted their oars in a single bank and were undecked or only partially decked. They were fast and graceful with high, curving stem and stern. In Homeric times some carried an *embolon,* a beak or ram, which became standard in succeeding centuries.

Biremes and triremes.   The bireme (a ship with two banks of oars), probably adopted from the Phoenicians, followed and became the leading warship of the 8th century BC. Greek biremes were probably about 80 feet (24 metres) long with a maximum beam around 10 feet. Within two or three generations the first triremes (ships with three vertically superimposed banks of oars) appeared. This type gradually took over as the primary warship, particularly after the Greeks' great sea victory at the Battle of Salamis (480 BC).

(margin note: The first triremes)

Like its predecessors, the trireme mounted a single mast with a broad, rectangular sail that could be furled. The mast was lowered and stowed when rowing into the wind or in battle. Built on an entirely different system from the Egyptians—with keel, frames, and planking—these were truly seagoing warships.

After Salamis, the trireme continued as the backbone of the Greek fleet, with the ram continuing as its primary

weapon. Its keel, like those of its predecessors, formed the principal-strength member, running the length of the ship and curving upward at each end. The ram, usually shod in bronze, formed a forward prolongation that gained effectiveness from the heavy keel back of it. Additional longitudinal strength came from a storming bridge, a gangway along the centreline from bow to stern along which the crew raced to board when a foe was rammed. Gradually, with ships becoming steadily heavier, boarding assumed greater importance and the ram lost some of its importance.

A trireme of the 5th century BC may have had a length of about 125 feet, a beam of 20 feet, and a draft of three feet. Manned by about 200 officers, seamen, and oarsmen (perhaps 85 on a side), with a small band of heavily armed *epibatai* (marines), under oars it could reach seven knots (seven nautical knots per hour; one knot equals 1.15 statute miles per hour or 1.85 kilometres per hour). Extremely light and highly maneuverable, the classical trireme represented the most concentrated application of human muscle power to military purposes ever devised. The oarsmen sat on three levels, which were slightly staggered laterally and fore and aft to achieve the maximum number of oarsmen for the size of the hull. In rowing, the oarsmen slid back and forth on leather cushions strapped to their buttocks; this enabled full use of the powerful muscles of the thighs and abdomen (see Figure 27).

With only scant room for provisions, such warships could not remain long at sea, and a voyage usually consisted of short hops from island to island or headland to headland. Even the largest triremes put into shore and beached for the night, resuming the passage in the morning, weather permitting. Light construction and little endurance made short distances between bases essential and frequent refits imperative.

Later developments. The trireme reached its peak development in Athens. By the middle of the 4th century BC, Athenians employed quadriremes (four-bank seating), with quinqueremes appearing soon thereafter. In the late 4th and early 3rd century BC an arms race developed in the eastern Mediterranean, producing even larger multibanked ships. Macedonia's rulers built 18-banked craft requiring crews of 1,800 men. Ptolemaic Egypt capped them with 20s and 30s. Ptolemy III even laid down a 40 (tesseraconter) with a design length of over 400 feet and calling for a crew of 4,000 rowers. The vessel was never actually used. (The multiplicity of "banks," once a puzzle to historians, signifies the number of rowers on each oar or row of oars rather than an almost unimaginable vertical piling-up of banks.)

Naval weapons of the galley era

This same arms race brought other changes of significance. Until the late 4th century BC, maneuver, marines, and the ram constituted a warship's offensive strength, and archers provided close-in fire. Demetrius I Poliorcetes of Macedonia is credited with introducing heavy missile weapons on ships at the end of the century, starting a trend that has continued to the present day. Demetrius' ships mounted crossbowlike catapults, for hurling heavy darts, and stone-throwing machines of the type the Romans later called ballistae. From this time on, large warships carried these weapons, enabling them to engage a foe at stand-off ranges, though ramming and boarding also continued.

Temporary wooden turrets—forecastles and sterncastles—were similarly fitted to provide elevated platforms for archers and slingers.

Following the fragmentation of the brief empire of Alexander the Great, sea power developed elsewhere. The city-state of Rhodes built a small but competent fleet to protect its vital shipping. Meanwhile to the west, Carthage, a state with ancient maritime origins, rose to prominence on the north coast of Africa and by about 300 BC had become the foremost Mediterranean naval power. Carthage's navy consisted probably of the same ram-galley types developed by its ancestral Phoenicians and by the Greeks.

Rome. Coincidentally, across the sea to the north the city-state of Rome expanded to include most of the southern Italian peninsula, with its extensive seacoast and maritime heritage. Rome's growth southward collided with Carthage's ambitions in Sicily, leading to the First Punic War, which began in 264 BC. Unlike their seafaring opponents, the Romans were not a naval power. When in the fourth year of the war Carthage sent a fleet against Sicily, Rome realized its fatal disadvantage and moved to remedy it. The Greek city-states it had conquered had long seagoing experience. Employing their shipbuilders and learning also from the foe, Rome built a fleet of triremes and quinqueremes, the latter patterned after a Carthaginian warship that ran aground in Roman territory early in the war.

Not content with copying the enemy's tactics, the Romans took land warfare to sea and forced the Carthaginians to fight on Roman terms. Each Roman galley had fitted in the bow a hinged gangplank with a grappling spike or hook (the *corvus*) in the forward end, thus providing a boarding ramp. They added to the crews many more marines than warships usually carried.

The gangplank and grappling hook

The Phoenicians and Greeks had emphasized ramming, with boarding as a secondary tactic. A Roman captain rammed and then dropped the gangplank. Ram and *corvus* locked the galleys together, and the Roman marines boarded, overwhelming the opponent. The Roman fleet had extraordinary success in the great naval Battle of Mylae off northeast Sicily, destroying or capturing 44 ships and 10,000 men. After other victories, and some defeats, by the end of the First Punic War, 241 BC, Rome had become the leading sea power.

As the Roman navy evolved, so did its warships. Though pictorial evidence is ambiguous, it seems clear that the gangplank and *corvus* disappeared as the Romans gained experience in sea warfare. Later Roman warships appear to have been conventional fully decked ram-galleys mounting one or two wooden turrets (probably dismountable) for archers. To the single mast with rectangular sail was added a bowsprit carrying a small sail, the artemon, Falces, or long spars tipped with blades, were used by Julius Caesar's fleet against the sailing vessels of the Veneti of northwestern Gaul to cut their rigging and immobilize them. Catapults and ballistae served as mechanical artillery, and it was under their fire that Caesar's legions landed in England.

Early Roman warships were all large; to escort merchantmen and combat pirates Rome found need for a lighter type, the liburnian. Probably developed by the pirates themselves, this was originally a light, fast unireme to
Figure 27: *Greek trireme of the 5th century BC.*
Powered by as many as 85 oarsmen on each side, the trireme was capable of seven knots and had a beaked prow for ramming enemy vessels.

which the Romans added a second bank of oars. In the Battle of Actium, 31 BC, Octavian's skilled fleet commander, Agrippa, used his liburnians to good effect. Although polyremes continued to be built after Actium, the liburnian became the predominant Roman man-of-war.

The Byzantine Empire. With the breakup of the western Roman Empire, naval organization and activity in the west decayed. In the eastern Roman Empire, however, the need for sea power was well appreciated. During the 11 centuries that the Roman Empire centred on Constantinople, the Byzantine rulers maintained a highly organized fleet. Their original type of warship was the liburnian, called in Greek the *dromōn;* it was built in several different sizes, the heavier designed to bear the weight of battle and the lighter single-bank dromons serving as cruisers and scouts.

Throughout the eastern Roman Empire's existence warships changed little except in rig and armament. An average large dromon measured up to 150 feet in length, with 100 oars and one or two fighting towers for marines. At some point early in the Christian era, the lateen sail, three-cornered and suspended from an angled yard, probably adopted from the Arabs, came into general use. Eastern warships had two or three masts. In a departure from classical customs, these were left in place in battle. Contemporary pictures show rams above the waterline.

Missile-launching weapons grew in size, some hurling projectiles as large as 1,000 pounds (450 kilograms) up to 750 yards (685 metres). Greek fire, a combustible material for setting fire to enemy ships, was invented in the 7th century or earlier. The various compounds passing under the name used a blend of some of the following: pitch, oil, charcoal, sulfur, phosphorus, and salt. As the composition of Greek fire was improved, tubes shaped into the mouths of savage monsters were placed in the bows of war galleys and the flaming substance, which water merely spread, was hurled on the enemy. Greek fire was an important factor in terrifying and repelling the Muslim fleet in sieges of Constantinople from the early 8th century on.

Viking vessels. By the beginning of the Viking period, about AD 800, the early and primitive Scandinavian craft had evolved into the well-known Viking ship, a sturdy, double-ended, clinker-built (*i.e.,* with overlapping planks) galley put together with iron nails and caulked with tarred rope. It had a mast and square sail, which was lowered in battle; high bow and stern, with removable dragon heads; and a single side rudder on the starboard (steerboard) quarter.

Viking vessels were essentially large open boats. Like the Homeric Greeks, the Vikings at first made no distinction between war and cargo ships, the same vessel serving either purpose as the occasion demanded. Later, however, they built larger ships specifically designed for war. By AD 1000 they sailed three categories of ship: those with fewer than 20 thwarts (40 rowers); those with up to 30; and the "great ships" with more than 30, which might be considered the battleship of the time. Expensive and unwieldy, though formidable in battle, the great ships were never numerous. The middle group, maneuverable and fast, proved most valuable.

Viking "long ships" played an important role in exploration (reaching Greenland and America before Columbus), in the consolidation of kingdoms in Scandinavia, and in far-ranging raids and conquests. In them the Norsemen invaded the British Isles and established themselves in Normandy, whence their descendants under William I the Conqueror crossed the Channel in 1066.

THE AGE OF GUN AND SAIL

To about the end of the 13th century, the typical ship in northern European waters remained a clinker-built, single-masted, square-rigged descendant of the long ship. In that century, and even more in the 14th, changes began that would bring an end to the long dominance of the oar in battle. In about AD 1200 came one of the great steps in the history of sail: the introduction, probably in the Netherlands, of the stern rudder. This rudder, along with the deep-draft hull, the bowsprit and, in time, additional masts, transformed the long ship into the true sailing ship, which could beat into the wind as well as sail with it.

Until the 15th century, northern ships probably continued to have single masts, though in the Mediterranean a two-mast rig carrying lateen (fore-and-aft) sails had existed for some time. Then change came rapidly in the north, spurred on by Henry V of England's construction of large and strongly built warships for his cross-Channel French campaigns. The remains of one of these, the *Grâce Dieu,* reflected the clinker-built construction of the Viking long ship, but they had a keel to beam ratio of about 2.5:1 and now carried a second mast.

Some historians believe that the *Grâce Dieu* carried a third mast. At any rate, in a few decades ships had three and, by the end of the century, large vessels mounted four masts carrying eight or more sails. A three-master carried a large sail on each mast and in addition a main topsail and the spritsail under the bowsprit—the rig, in fact, of Christopher Columbus' *Santa Maria* in 1492. Ships, no longer dependent on fair winds, could and did range the world.

The beamier round sailing ship used for commerce also became the warship when the need arose. In times of war, temporary wooden castles were added at the bow and stern to provide bulwarked platforms for archers and slingers. A complement of men-at-arms embarked, in addition to the ship's seamen. Tactics were usually simple and straightforward, opposing fleets closing and attempting to beat down each other's archers before grappling and boarding. At war's end, off came the castles, and the ship went back to trading.

The trading vessel that could be promptly adapted to war did not, however, fulfill the need of the European nations for navies. The coming of gunpowder and the period of world exploration brought changes that were to cause the sailing man-of-war to become more and more distinct from the merchantman.

Gun-armed warships. The employment of guns afloat, bringing a slow but progressive revolution in warship construction and naval tactics, had its first small beginnings by the 14th century. The first guns used at sea, undoubtedly hand weapons, were probably in Mediterranean galleys in the 13th or early 14th century. Such weapons played a minor role. In fact, in the numerous sea battles of the Greeks, Genoese, Moors, Turks, and Venetians during this period there is no mention of guns. But by the middle of the 14th century, the English, French, Spanish, and other navies mounted guns. Most were relatively small swivel pieces or breech-loading deck guns located in the castles fore and aft, but heavier guns were added later. The Mediterranean galleys of Venice, Turkey, and Spain at first simply mounted a heavy gun rigidly in a timber bed that was fixed to fire the gun forward over the bow. By the late 15th century these rigid mounts gave way to sliding mounts for the main centreline bow gun, as the pieces were called. Though some of these pieces were quite large, the light structure of a galley meant that there was only one large gun per vessel.

European guns were originally built up of wrought-iron bars welded together to form a tube, then banded with a thick iron hoop. Initially, they were breechloaders with an open trough at the rear of the barrel through which the ball was loaded and a cylindrical chamber, filled with powder, inserted and wedged tight. They were replaced after 1500 by brass muzzle-loaders, cast in one piece. Some of these muzzle-loaders attained great size for their day; by the mid-16th century even some 60-pounders (firing 60-pound solid shot) were mounted in the largest ships. In this century also, increasing knowledge of iron metallurgy led to the production of cast-iron cannon that slowly replaced the brass guns in ships, though brass remained predominant for the lighter calibre well into the 19th century.

The Portuguese and Spanish, and then the French, seem to have been the first to cover transoceanic distances with cannon-armed warships. Vasco da Gama reached Calicut in India in 1498 with a squadron of cannon-armed carracks, and the Portuguese gained a number of signal victories over their Muslim opponents in the East in the early years of the 16th century using standoff artillery tactics that their foes could not match. The Spanish were pa-

The rudder and the true sailing ship

The first naval guns

trolling the waters of the Caribbean in ships well-provided with wrought-iron breech-loading cannon by the 1520s or '30s, if not before, and heavily armed French raiders were not far behind.

Henry VII of England created the first true oceangoing battle fleet. The "king's ships" carried many guns, but most of these weapons were small breechloaders. Following him, Henry VIII initiated gunports in English warships, a development that was to have a far-reaching effect on man-of-war design. Neither stability nor structural strength favoured heavy guns in the high castles built upon the deck, so that Henry's introduction of gunports, at first low in the waist of the ship and afterward along the full broadside, made possible the true heavy-gun warship. The cutting of gunports in the hull must also have been a factor in causing the northern nations to shift from clinker-built ships to caravels with flush-fitting planks, a change that took place in the early 1500s.

The armament of an English man-of-war of the early 16th century consisted of four or five short-barreled cannon, or curtals, a similar number of demicannon and culverins. The average cannon, a short-range gun, hurled an iron ball of about 50 pounds, and the demicannon one of 32 pounds. The culverin, a longer and stronger gun, fired a smaller shot over a longer range and was likely to be more accurate at other than point-blank range. Supplementing these standoff "ship killers," in descending size of ball fired (down to only several ounces), were the smaller demiculverin, saker (quarter culverin), falcon (half saker), falconet, and robinet.

A great warship of the 16th century mounted a total of large and small pieces approximating the numbers mounted in battleships of World War II. For its original complement in 1514, Henry VIII's best-known warship, the *Henry Grâce à Dieu*, had 186 guns. Most of these were small, but they also included a number of iron "great guns."

As the 17th century advanced, guns and gunpowder improved. Gun carriages were given heavy wooden sides called brackets, which had sockets for the gun trunnions and were joined by similar flat timbers called transoms. The carriage was supported on wooden trucks and hauled out after recoil by heavy tackle.

From oar to sail. *The galleass.* The coming of mighty men-of-war did not mean the immediate end of oared warships. In fact, some types of galleys and oared gunboats continued to serve well into the 19th century. Indeed, the Battle of Lepanto (1571), in which a combined European fleet defeated the Turkish fleet, differed little from traditional galley warfare with two exceptions. First, the scale of the action was very large, with more than 200 cannon-armed galleys on each side. Each of those galleys was propelled by 50 to 200 oarsmen and carried at least 50 additional men to fight and to man the guns and sails. Second, the European line of battle included six Venetian galleasses, a compromise type developed in the transition from oar to sail. These huge vessels, which depended on sail as well as oar, bristled with guns, including heavy ones in broadside. Although cumbersome to maneuver, their concentrated fire contributed importantly to victory.

Galleasses outside the Mediterranean differed somewhat from Venice's in that they were basically full-rigged sailing ships carrying broadsides of heavy guns and a bank of auxiliary oars for mobility. The hybrid existed only in small numbers and soon passed out of fashion to the north.

The galleon. The "great ships" of Henry VII and Henry VIII were carracks: starting basically with the lines of beamy, seaworthy merchant ships, designers had added stronger timbers, masts, sailpower, broadside guns, and high-built forecastles and aftercastles. In the galleon, the successor to the carrack, the general principles of design of sailing men-of-war were established, and they ruled, without fundamental change, for three centuries. The galleon retained certain characteristics of the galley, such as its slender shape, and in fact it had a greater length-to-beam ratio than the carrack. But the carrack's high-built forecastle, which tended to catch the wind and thus make the ship unmaneuverable, was eliminated from the galleon's design. The resulting ship was much more seaworthy. Like

carracks, the larger galleons might carry a single mizzenmast or two relatively small masts, the second being called the bonaventure.

In the longer, leaner galleon, the number of heavy guns was increased until they ran the full length of the ship's broadside in one or two tiers (and later three).

The galleon came into favour in northern Europe during the middle of the 16th century. The far-ranging experience of mariners and improved construction techniques led to great fighting ships that were both lower in the water and more seaworthy than their predecessors. The sides now sloped inward from the lowest gun deck up to the weather deck. This "tumble home" helped concentrate the weight of the large broadside guns toward the centreline, improving the ship's stability.

By this time it had become normal for warships to mount powerful broadsides of 28 or more ship-smashing guns, a much heavier armament in proportion to their size than their predecessors. For their handy, maneuverable ships, the British had relatively large cannon carried in broadsides. Thus they were designed for off-fighting, permitting the English fleet to get the most out of its ships' superior maneuvering qualities. When the Spanish Armada arrived in 1588, the British sought and fought a sea battle with ship-killing guns, rather than the conventional fleet engagement of the past that concentrated on ramming, boarding, and killing men in hand-to-hand combat. With superior ability and long-range culverins, the English ships punished the invading fleet outside the effective range of the heavy short-range cannon the Spanish favoured. This historic running battle of July 1588 closed one era and opened a greater one of big-gun sailing navies.

Ship of the line. The late Elizabethan galleon that began the true fighting ship of the line reached its culmination in England's *Prince Royal* of 1610 and the larger *Sovereign of the Seas* of 1637, along with similar great ships in other European navies. These two English ships mounted broadside guns on three decks; the *Sovereign of the Seas,* the most formidable ship afloat of its time, carried 100 guns. In this mobile fortress displacing approximately 1,500 tons, there was some reduction of height; the bonaventure mizzen disappeared, leaving the standard three masts that capital ships thereafter carried (see Figure 28).

Soon ships began to be standardized into different categories. James I organized his ships into four ranks, and, by the mid-17th century, six "rates" existed as a general concept, though not yet a system. The number of guns a ship carried determined its rate, with a first-rater mounting 100 guns and a sixth-rater 18. An important improvement came in the standardization of batteries in the higher rates

Guns and heavy guns (margin note)

Figure 28: *The Sovereign of the Seas, English galleon of the Anglo-Dutch Wars.*
Launched in 1637, this was the largest warship of its time and the first to carry 100 guns. The prominent beak at its bow soon went out of fashion, but its three gun decks and low sterncastle and forecastle set the pattern for ships of the line for the rest of the sailing era. Contemporary engraving by J. Jayne.

so that guns on the same deck were of the same weight and calibre rather than mixed, as originally in the *Sovereign of the Seas.* Near the end of the century, guns began to be described by their weight and calibre, with the 32-pounder long gun favoured as the standard lower-deck weapon for British warships.

The frequent hard-fought sea battles of the 17th century, particularly in the Anglo-Dutch wars, led to the column formation of heavy warships called line ahead. In the line formation, each warship followed in the wake of the ship ahead so that every ship in the line had a clear field of fire for a broadside discharge of its guns. The adoption of line-ahead tactics made it necessary to standardize the battle line, which had consisted of ships of widely varying strength. Now only the more powerful warships were considered suitable "to lie in the line of battle." Hence the origin by the 1700s of the term line-of-battle ship, or the ship of the line, and, in the second half of the 19th century, the derived term battleship—ships that could hit the hardest and endure the most punishment.

The great two- and three-deckers

Some first-raters were built to carry as many as 136 guns, but, because the biggest ships were often cumbersome, relatively few were built. The handier 74-gun third-rater proved particularly successful, combining sufficient hitting power with better speed and maneuverability. Most of the ships of the line of the late 18th and early 19th centuries were 74s. One of these might be approximately 175 feet long with two full gun decks, the lower mounting the heaviest guns, by the Napoleonic Wars usually 32-pounders. The upper gun deck customarily carried 24-pounders, while the forecastle and quarterdeck mounted lighter guns. The bigger ships were similar but had three covered gun decks instead of two. Viscount Nelson's *Victory,* launched in 1765 and preserved in dry dock as it was at Trafalgar in 1805, is a classic example of this powerful type.

Warships gradually improved in design through the 17th and 18th centuries. New types of sails, providing more canvas and more versatile combinations for varying weather conditions, such as staysails and the jib sail, came into use in the 17th century. Soon thereafter the steering wheel replaced the old whip staff, or tiller.

Frigates and smaller vessels. Ships of the line, first to fourth rates, had strong, fast frigates as consorts. This ancestor of the modern cruiser evolved during the mid-18th century for scouting, patrol, and escort, as well as for attacking enemy merchantmen. The frigate carried its main battery on a single gun deck, with other guns on forecastle and quarterdeck. Like ships of the line, they varied in size and armament, ranging from about 24 guns in early small frigates to as many as 56 in some of the last. Two classic examples, still preserved, are the U.S. Navy's *Constitution,* with 44 guns, and *Constellation,* with 38.

Smaller vessels aided frigates in their blockade, escort, commerce raiding, and other duties. The single-masted cutter served as scout and coastal patrol craft. Brig and schooner-rigged types, generally called sloops of war, by the time of the American Revolution grew into the three-masted, square-rigged "ship sloop." Called a corvette on the Continent, the fast ship sloop complemented frigates on the fringes of the fleet. Smaller sloops, schooners, brigs, and luggers were widely used for special service. Fleets also needed ordnance and supply ships and other auxiliaries; these were usually merchantmen taken into service in war emergency. Converted merchantmen, such as John Paul Jones's *Bonhomme Richard,* often played combat roles. Fleets also had various special types, such as fire ships and bomb ketches. The latter, with two large mortars hurling bombs of about 200 pounds, were developed by France in the late 1600s and were used with devastating effect against Barbary pirate ports.

THE AGE OF STEAM AND IRON

As the Industrial Revolution unfolded in the 19th century, the age of wooden-hulled sailing ships gave way to that of steam-powered iron ships. Phenomenal changes took place in nearly every aspect of warship design, operation, and tactics. These changes ended the reign of the majestic ship of the line by the mid-1800s, but another half century

elapsed before it was clear what form its replacement as the backbone of fleets would take.

Toward the ironclad. The change from wood to iron came slowly, in considerable part because the introduction of steam power required new techniques and experience in shipbuilding. The general use of iron for warships awaited the full realization of the value of the shell gun and the resulting need for armour, which were first demonstrated in the employment of armoured batteries in the Crimean War and in the battle between the *Monitor* and *Merrimack* in the American Civil War. The changes may be summarized under three headings: propulsion, armament, and armour.

Propulsion. Steam for propulsion of vessels was tried with varying success in several countries during the late 18th century. Engines and supporting machinery were at first not adequate for this fundamental advance in ship capability, but useful steam craft appeared in the early 1800s, suitable for operation on inland and coastal waterways. The earliest steam warship was the *Demologos* of the U.S. Navy (renamed *Fulton* after its designer, Robert Fulton). Built in the War of 1812, this well-gunned, double-hulled, low-powered ship cruised briefly in the New York Harbor area before the war ended and later was destroyed by an accidental fire.

First steam warship

The earliest steam warships in action were small paddle wheelers used by British and American navies against pirates and other weak foes. As engines gradually improved, navies experimented with them in standard warships, first as auxiliaries to sail, which was then essential for endurance. The paddle wheels were particularly vulnerable to enemy fire. In 1843, through the drive of Captain Robert Field Stockton of the U.S. Navy and the inventive skill of John Ericsson, a Swede whom Stockton brought to America, the United States launched the world's first screw-driven steam man-of-war, USS *Princeton,* a large 10-gun sloop.

The screw propeller was an old idea going back to Archimedes, but, with Stockton's assistance, Ericsson had made it effective for large warships, as Sir Francis Pettit Smith was doing at about the same time in England for large merchantmen. By the mid-1840s, boilers, engines, and machinery had improved to the point that thereafter practically all of the new warships had steam propulsion, though they also still carried sails.

Among the advances of this period were two other milestones. In 1834 Samuel Hall of England patented a type of steam condenser that made it possible to use fresh instead of corrosive salt water for boilers. In 1824 James Peter Allaire of the United States invented the compound-expansion steam engine, in which the steam was used in a second cylinder at a lower pressure after it had done its work in the first. Eventually it was made practical by progress in metallurgy and engineering; in 1854 John Elder, shipbuilder on the River Clyde, installed a successful two-stage engine in the merchant steamer *Brandon.* The higher efficiency was of great importance for ocean-keeping navies.

Armament. The basic changes in armament that were to take place in the 19th and 20th centuries had begun in the 18th century. In the British navy steps to make possible heavier long-range guns began with the introduction of strong springs to take up the first shock of the gun's recoil after firing, aided by inclined-plane wedges behind the trucks to coax the gun forward into firing position after recoil. Flintlocks pulled by a lanyard, instead of match, fired the guns. Sights also improved. In the early 1800s navies began to employ mercury fulminate in percussion caps to initiate firing. Efficient percussion locks came into use within a few years.

Smoothbore guns were still inaccurate, and successful efforts were made to bring back the rifled barrels, as well as the breech loading, of early guns, thus increasing their speed and accuracy of fire. The bore of a rifled gun barrel had spiral grooves cut into it that caused a projectile fired from it to spin in flight; if this projectile was shaped in the form of a cylinder with a cone-shaped forward tip, spin enabled it to fly through the air with its pointed end forward at all times. This improved aerodynamics gave

From smooth-bore to rifle

the shell a more accurate course of flight and a longer range. Because a projectile could not be rammed down the muzzle of a rifled barrel, the use of rifling had to await the design of an efficient breech-loading mechanism. In the 1840s, Italian and Austrian inventors brought out sliding-wedge breechblocks. Later the French developed an interrupted screw system, originally an American invention. A British firm produced a rifled breech-loading gun that the Royal Navy used until 1864, when a number of accidents brought a temporary reversion to muzzle-loaders. But defects were eventually remedied, and breech loading brought phenomenal increases in rates of fire.

French 6.5-inch (165-millimetre) cast-iron rifled guns in the Crimean War demonstrated superiority in range, destructive power, and accuracy. They helped impress all of the navies with the need for rifling. Slower-burning powder was also badly needed. Black powder had gradually been improved during 600 years of use in firearms, but it still retained its primary defect, too-rapid burning (and hence the creation of gas pressures so high that they could burst a gun barrel upon firing). The use of rapid-burning powder required keeping the size of the charge down (and therefore the range) to prevent the bursting of even the best guns. Just before the American Civil War the U.S. Army developed large, perforated, dense grains of black powder that burned more slowly and thus were a start toward the controlled burning ultimately achieved with smokeless powder.

Exploding shell A development equal in importance to the rifling of naval guns was the replacement of solid iron cannonballs with large shells that exploded upon impact. Shell guns in warships' main batteries were preceded by bombs fired from mortars, small shell guns, and solid hot shot heated to cherry red. A principal architect in bringing big shell guns to sea was Henri-Joseph Paixhans, a general of French artillery. The first large shell guns from Paixhans' design, chambered howitzers firing a 62.5-pound shell (thicker-walled than bombs to penetrate before exploding) was tested in 1824 against a moored frigate with remarkable accuracy and incendiary effect.

The new guns began to come into use afloat in the 1830s, a French squadron firing them in the bombardment of Vera Cruz, Mex. The U.S. Navy began installation of the new guns, including 16 eight-inch shell guns in the three-decker *Pennsylvania,* along with 104 32-pounder solid-shot guns. The British made similar installations. There was good reason for navies to proceed cautiously, as the production of shell guns at first encountered many manufacturing problems. (Indeed, in a gala demonstration of the 12-inch shell guns on the USS *Princeton* for President John Tyler, one of the guns blew up, killing the secretary of the navy and several others.) In the event, improvements in metallurgy, gun construction, and fire control—along with the maneuverability of steam warships—at last led to the important extension of range that the big gun had promised from the beginning.

In 1853 the dramatic destruction of a weaker Turkish squadron by a Russian fleet in the harbour of Sinop of Turkey's Black Sea coast attracted world attention and increased interest in shell guns. England, the United States, and others built big steam frigates (as they were misleadingly called) with big shell guns. Their great striking power and maneuverability under steam made them the capital ships of the day, superseding the ship of the line for a long time before the ironclads took over.

Larger guns, increased powder charges, and greater tube pressures were made possible by the replacement of cast iron by built-up wrought-iron guns (later, cast steel and, eventually, forged steel were used). Hoops were shrunk on over the powder chamber and breech end of the tube to give the strength required for the greater internal pressures sustained by these guns upon firing.

Armour. The use of larger guns with more penetrating power and explosive shells made armour plating imperative. Among early experiments were floating armoured batteries built for the Crimean War. Heavy wrought-iron plates over a thick wooden backing gave these flat-bottomed vessels outstanding protection as they carried large-shell guns close inshore.

Other developments followed swiftly. The British soon built the first iron-hulled floating batteries. The French followed with the *Gloire,* the first seagoing armoured warship, protected throughout her entire length by a wrought-iron belt of 4.3- to 4.7-inch armour backed by 26 inches of wood. Displacing 5,617 tons, she mounted 36 large shell guns and could steam at 13.5 knots; a three-masted sailing rig supplemented the engines. *Gloire* was the first of a series of ironclads laid down by Napoleon III; 13 similar ships soon followed, then two-decker armoured rams. Great Britain countered with the *Warrior,* the first iron-hulled, seagoing, armoured man-of-war. Much larger than the *Gloire,* she displaced 9,210 tons, mounted 28 seven-inch shell guns, had slightly lighter armour, carried sails, and was one knot faster.

Iron ship armour

These first ironclads were commissioned on the eve of the American Civil War, in which ironclads were destined to take a decisive part. The war itself produced several spectacular developments, including pioneer submarines, the first aircraft carriers (to handle balloons for observation), and the torpedo boat, one of several means the Confederates explored in trying to break the blockade. These little craft had weak steam engines and mounted a torpedo lashed to a spar projecting from the bow. Called Davids, they were weak but definite forerunners of the torpedo boat and the versatile destroyer.

Ironclad warships were crucial, perhaps decisive, in the North's victory over the South. Partial ironclads appeared early on the western rivers and spearheaded Union general Ulysses Grant's victories in 1862. River and coastal ironclads (ultimately, mostly monitors) dominated the war against the South in attacks from the sea and in decisive support of land operations from the Mississippi system to the Chesapeake Bay and James River. Most memorable of the combats was the duel between the *Monitor* and *Virginia* (better known as the *Merrimack*). When the Federal forces lost Norfolk Naval Shipyard in Portsmouth, Va., in April 1861, they burned several warships, including the heavy steam frigate *Merrimack.* The Confederates raised the *Merrimack,* installed a ram and slanting casemates made from railroad track over thick wooden backing, as had been done in the *Gloire,* and renamed it *Virginia.* Mounting 10 guns, including four rifled ones, the *Virginia,* with yard workmen still on board finishing up, sailed on March 8, 1862, for its trial run. Defying concentrated fire of ship and shore batteries, it sank two ships of the Union's wooden blockading fleet before retiring with the ebbing tide. In this dramatic moment John Ericsson's *Monitor* arrived from New York during the middle of the night. Displacing fewer than 1,000 tons, less than one-third of the *Virginia,* the *Monitor* had a boxlike iron hull supporting an iron-plated wooden raft on which revolved the turret. The 172-foot-long vessel had little freeboard except for the thickly armoured rotating turret within which were mounted two 11-inch smoothbores.

The *Monitor* and *Merrimack*

The *Monitor* had many deficiencies. Not really a seagoing warship, it had nearly sunk on its voyage down from New York and did sink on its next sea voyage. Yet it proved the equal of its rival in their duel on March 9. The battle ended in a draw with neither ship seriously injured, but the repercussions of this first duel between completely ironclad warships swept the world.

On April 4, scarcely more time than required for a ship to cross the Atlantic, Great Britain ordered the 131-gun ship of the line, the *Royal Sovereign,* to be cut down, armoured, and fitted with turrets. Only three and a half weeks later Great Britain laid down the *Prince Albert,* the Royal Navy's first iron-hulled turret ship, mounting four turrets.

The Union Navy ordered 66 coastal and river monitors; these were low freeboard ships that were unsuitable for high-seas action and rarely suitable for long voyages. Many were not completed in time for war service. Besides the *Virginia,* the Confederates began a number of other ironclads. Several of these rendered valuable service and probably lengthened the war, but most had to be destroyed before completion. Out of a combination of characteristics of the *Monitor* and *Virginia* types evolved the battleship, which was next to rule the sea.

Toward the battleship. The later 19th century continued to be a time of great flux in warship design. European nations tried numerous arrangements of guns and armour, such as centreline turrets, a central armoured citadel with large guns on turntables at each corner (see Figure 29), lightly armoured big guns topside in barbettes (open-top breastworks), torpedoes in even the largest vessels, and substitution of high speed for armour.

For a time even the ancient ram was revived. When the Austrians won the Battle of Lissa from the Italians in 1866 by ramming, its value for the future seemed confirmed. Hence for years most large ships carried rams, which proved to be more dangerous to friend than foe when ships were sunk in peacetime collisions.

The first torpedoes

This period also saw a fundamental advance in underwater weaponry with the invention of the locomotive torpedo. After being presented with the idea by an Austrian naval captain in 1864, a British engineer named Robert Whitehead produced a projectile that was driven by compressed air and was designed to strike a ship's unprotected hull below the waterline. The Whitehead torpedo, as it was quickly adapted by the European navies, was about 16 inches in diameter and had a range of about 1,000 yards at approximately seven knots.

Engines for all the types of warships steadily improved as stronger metals made possible higher steam pressures and weight reduction. In the 1870s a third cylinder was added onto the two-stage compound steam engine to make the triple expansion engine, and in the 1890s a fourth cylinder was added. These improvements on the traditional reciprocating steam engine provided a marked increase in speed that was surpassed only by the radical innovation of the steam turbine at the end of the century.

The National Maritime Museum, London

Figure 29: HMS Inflexible, "central citadel" battleship of the Royal Navy.
Launched in 1876, it mounted four 80-ton, 16-inch muzzle-loading guns in two hydraulically powered turrets. For greater stability, the engines and powder magazines were gathered toward the centre of the ship and protected by up to 24 inches of iron. The masts were removed in the 1880s.

Ships. A trend toward the centreline-turret, big-gun battleship finally became clear. In it were combined the seagoing hull, armour, and habitability of the *Virginia, Gloire,* and *Warrior* with the revolving turret and big guns of the *Monitor.*

HMS *Monarch,* 8,300 tons, mounting four 12-inch guns in two turrets, and commissioned in 1869, was perhaps the first true seagoing turret warship. HMS *Devastation,* 9,330 tons, four 12-inch guns in two turrets, and massively armoured, was completed four years later without sail and was a next step toward the ultimate 20th-century battleship, a ship with an armoured citadel around the propulsion plant, powder magazines, and handling rooms. Rising out of it, protecting big guns and crews, were barbettes and turrets. The main battery shrank to a few powerful guns, but these took the place of many in broadside because of their great size and ability to fire through a wide arc of bearings.

The change was vividly illustrated by the "new navy" the

United States began building in the 1880s, consisting not of improved monitors but of powerful seagoing capital ships with mixed-calibre main batteries. Displacing 11,700 tons, these vessels had 18-inch belt armour and a speed of 15 knots and mounted four 13-inch guns in two turrets. They also mounted eight eight-inch guns in four turrets, smaller guns for defense against torpedo boats, and six torpedo tubes. The plan was, as in other navies, to employ the heavy guns against an enemy ship's armour-protected machinery and magazines while the faster-firing eight-inch guns attacked its relatively unprotected superstructure.

Armoured cruisers

The armoured cruiser was developed in this period as a large, fast vessel armed with intermediate-calibre guns and protected by armoured deck and medium-weight belt armour. Designed for commerce protection and raiding, as well as to cooperate with the battle line in fleet action, it was considered powerful enough and sufficiently protected to fight any ship capable of catching it and able to outrun battleships. Some even held it should become the principal warship.

Less heavily armoured was the protected cruiser, the engines and magazines of which were shielded by an armoured deck, but which lacked an armour belt. Unprotected cruisers had little or no armour, carried fairly light guns, and were designed primarily for scouting, patrolling, and raiding.

Carrying the new self-propelled torpedo, the torpedo boat had great potential, particularly under conditions of low visibility. Small, unseaworthy, and useful only in restricted waters with the then-short-range, slow torpedoes, the new boats did not immediately live up to expectations; nevertheless, as craft and torpedo improved, they were soon regarded as a major menace.

Armour. Early hull armour had been of wrought iron backed by wood. To increase resistance against ever more powerful rifled guns, compound armour of steel backed with iron was devised to combine steel's surface hardness with iron's resiliency. The firm Schneider & Cie in France invented an oil-tempering process to produce a homogeneous steel plate that had good resiliency and greater resistance than compound armour. The later addition of nickel further improved its resistance.

Steel-armour-piercing shells came into use in the late 1880s, again threatening the armoured ship. Accordingly, an American engineer, Hayward Augustus Harvey, perfected a face-hardening process, applying carbon to the face of the steel plate at very high temperatures for an extended period and tempering. Harvey nickel-steel armour superseded earlier types. Then, in 1894, the Krupp firm of Germany devised hot-gas tempering, based on Harvey's process, which in turn became standard with world navies. Later, the addition of chromium to nickel steel was found to be a further improvement.

Armament. The impact of developments in guns and powder exceeded even that of warship design in their effect upon navies. In the two decades after the American Civil War the main difficulties with breech mechanisms were resolved. Better guns, along with breech-loading, made possible both longer ranges and higher rates of fire.

New powders were equally important. About 1880 brown or cocoa powder appeared, employing incompletely charred wood. It burned slower than black powder and hence furnished a sustained burning that was effective ballistically but did not create excessive pressures within the gun barrel. To take advantage of this for longer-range firing, gun-barrel lengths jumped to 30–35 times bore diameter.

Several nations began to achieve success with smokeless powder of nitrated cellulose and usually some nitroglycerin. With greater striking power available, armour-piercing projectiles became more formidable. These were originally solid shot designed simply to punch through armour plate. In the 1890s, better steel and fuses made it possible to add an explosive charge. The resulting semi-armour-piercing shells became highly destructive, and in time all of the armour-piercing projectiles carried explosive charges.

In 1881 the British Admiralty advertised for an anti-torpedo-boat gun to fire cased ammunition at a rate of 12

Armour-piercing projectiles

shots per minute. Benjamin Berkeley Hotchkiss, an American ordnance engineer with a factory in Paris, produced a series of one-, three-, and six-pounder rapid-fire guns that vastly increased the rate of fire for small guns.

(E.McN.E./R.L.Sc./J.C.Re./J.F.G.)

THE AGE OF BIG GUN AND TORPEDO

From the late 19th century through World War I, the greatest driving force in warship development was the rivalry between the big gun and the torpedo. Improvements in these weapons had immense influence on the design and use of surface warships, from the huge dreadnought battleships to the small torpedo boat.

Armament. *Guns.* By 1900 a major change had occurred in the handling of the very heavy main guns, those of 11 to 13.5 inches calibre that fired shells weighing up to 1,300 pounds. In the 1890s such weapons often fired no faster than once every five minutes, compared to the five to 10 rounds per minute fired by a six-inch gun. As power control became easier and more precise, the big guns became more effective. By 1900 it was possible for a 12-inch gun to fire one or two aimed shots per minute.

Meanwhile, the standard of heavy-gun marksmanship began to improve. Although rifled guns had grown bigger and muzzle velocity had increased throughout the late 19th century, there had been no corresponding improvement in fire control. For this reason, effective battle ranges had not extended much beyond 3,000 to 4,000 yards. Then it was discovered that a ship's roll and pitch could be systematically compensated for, so that each shot could be fired at the same angle to the sea and reach almost exactly the same range. Greater accuracy could be achieved by firing groups of shells, or salvos, bunched around the estimated range. The pattern of splashes raised by a salvo would then make corrections possible. By the

The growing range of naval gunnery

end of World War I, fire control had improved enough that guns firing 15,000 to 20,000 yards could attain a hit rate of 5 percent. This meant that a ship firing 10 heavy guns at the rate of once or twice per minute could expect a hit after two or three minutes.

Increased range was valuable for two reasons. First, a ship that could hit at ranges beyond the capabilities of its enemies could stand off and destroy them at leisure. Second, improved gun range increased protection against the new, longer-range torpedoes.

Torpedoes. Modifications and adaptations of the original Whitehead design quickly made the torpedo a formidable weapon. Directional control was greatly improved in the 1890s by the use of a gyroscope to control the steering rudders. Another significant improvement was the use of heat engines for propulsion. British firms, introducing both heat engines and contrarotating propellers, advanced to the high-performance, steam-driven Mark IV torpedo of 1917. Concurrently with this development, an American firm, E.W. Bliss Company, successfully used a turbine to drive a modified Whitehead design. (This Bliss-Leavitt torpedo remained in extensive use until World War II.) By 1914, torpedoes were usually 18 or 21 inches in diameter and could reach almost 4,000 yards at 45 knots or 10,000 yards at close to 30 knots.

Armour. The torpedo threat forced ship designers to provide battleships with underwater protection. Schemes to place coal bunkers near the outside of the ship proved impractical, but research during World War I showed that the basic idea of keeping the underwater explosion at a distance from the interior of the ship was correct. In the Royal Navy, existing ships were fitted with external bulges or "blisters" to keep the explosion farther outboard, and new ships were built with specially designed layers of compartments designed to absorb the shock of explosion.

During the war it also became apparent that the longer firing ranges meant that more shells would fall onto a ship's deck than on its side armour. Because these ranges were experienced at the Battle of Jutland, ships designed afterward with stronger deck armour were called post-Jutland.

Propulsion. *Steam turbines.* While weapons were the main driving force in warship development, changes in propulsion were also important. In 1890, propulsion was

exclusively by reciprocating (*i.e.,* piston) steam engines, which were limited in power and tended to vibrate. To escape these limits, warship designers adopted steam turbines, which ran more smoothly and had no inherent limits. Turbines were applied to destroyers from about 1900 and to battleships from 1906.

The main drawback of turbine propulsion was that really efficient turbines ran too fast to drive efficient propellers. The solution was to reduce turbine speeds to acceptable propeller speeds through gearing. By 1918, single-reduction gearing was commonplace. Late in the interwar period, the U.S. Navy adopted double-reduction gearing, which permitted even higher turbine speeds without requiring propellers to run any faster.

Fuel. Fuel also became a major issue. Coal was relatively inexpensive and easily available; however, it did not burn cleanly and was difficult to transfer from ship to ship at sea. Oil, on the other hand, burned cleanly, and it could be transferred easily at sea. Also, it had a higher thermal content than coal, so that the same weight or volume of oil could drive a ship much farther. The United States shifted to oil fuel in new ships in about 1910 and converted its remaining coal-burning warships after World War I. Beginning with the Queen Elizabeth class of battleships in 1915–16, Britain switched to oil. The other navies followed suit after the war.

From coal to oil

Internal combustion. In contrast to the steam engine, a gasoline or diesel engine often needed no tending at all, could be very compact, and could start and stop quite easily. Such engines made it possible to build small, fast coastal minesweepers, subchasers, and motor torpedo boats. Internal combustion was thought to be especially suitable to subchasers, which would have to stop their engines while listening for a submarine and then start them up suddenly when something was heard.

Battleships. A battleship entering service in 1900 typically mounted a mixed battery of four heavy (11- to 13.5-inch) guns in two twin turrets, about a dozen secondary guns of six to nine inches, and small, fast-firing guns of three inches or less for beating off torpedo-boat attacks. These ships usually displaced 12,000 to 18,000 tons.

By 1904 studies reinforced by battle experience in the Spanish-American and Russo-Japanese wars indicated that fire from large guns at longer ranges was more effective than mixed-battery fire closer in. Only bigger shells could do serious damage to well-armoured ships. Moreover, the shells fired from guns of many different calibres produced a confusing pattern of splashes in the water that made the correcting of aim and range quite difficult. Effectively increasing range, then, depended upon abandoning the multiple-calibre pattern of previous battleship armament in favour of a single-calibre armament. Several navies reached this conclusion simultaneously, but the British were the first to produce such a ship, HMS *Dreadnought,* completed in 1906. Displacing about 18,000 tons, it carried 10 12-inch guns; its only other armament consisted of three-inch weapons intended to fight off destroyers.

Dreadnought and the all-big-gun ship

The *Dreadnought* gave its name to an entirely new class of battleships of the most advanced design. By 1914 the Royal Navy had 22 dreadnoughts (another 13 were completed during World War I), Germany built a total of 19 (five completed after 1914), and the United States completed 22 (14 of them after 1914). Japan and Italy built six, while Russia and France each built seven. Not all of these ships were strictly equivalent. Unlike its immediate German and American contemporaries, the *Dreadnought* had steam turbines in place of reciprocating engines. These enabled it to attain a speed of 21 knots, which was hitherto achieved only by cruisers. (Contemporary battleships were generally limited to about 18 knots.) Thus, in mobility as well as in size, the *Dreadnought* began a new era.

HMS *Dreadnought* also marked a beginning of rapid development in big-gun firepower. In 1909 the Royal Navy laid down HMS *Orion,* the first "super dreadnought," which displaced 22,500 tons and was armed with 13.5-inch guns (see Figure 30). The U.S. Navy followed with ships armed with 14-inch guns. Then, on the eve of World War I, the Royal Navy went a step further with HMS *Queen Elizabeth,* armed with 15-inch guns and capable,

Figure 30: *HMS Orion, super dreadnought battleship of the Royal Navy.*
Heavier than HMS *Dreadnought* but just as fast, this ship mounted 10 13.5-inch guns of
greater armour-piercing power in five turrets along the centreline of the vessel. The *Orion* was
present at the Battle of Jutland in 1916 and was scrapped under the Washington Treaty of
1922.

The National Maritime Museum, London

in theory, of 25 knots. World War I stopped the growth of British and German battleships, but the United States and Japan continued to build ships exceeding 30,000 tons displacement. In 1916 both countries adopted the 16-inch gun, which fired a shell of approximately 2,100 pounds. Such guns could be aimed to hit at ranges as great as 20,000 yards.

The battleship saw little combat in World War I, yet, despite submarines, aircraft, and destroyers, the outcome of the war still hinged upon control of the sea by the battleship. Had superiority in battleships passed to Germany, Britain would have been lost, and the Allies would have lost the war. The one moment when this might have happened was the only large-scale clash of battleships, the Battle of Jutland. Fought in May 1916 in mist, fog, and darkness, Jutland revealed the strengths and weaknesses of battleships and battle cruisers. Three British battle cruisers were lost. Several German battleships, thanks to watertight subdivision and efficient damage-control systems, survived despite more hits. But the British advantage in numbers was decisive, and Germany turned to the submarine to counter the Allied blockade.

Cruisers. HMS *Dreadnought* made earlier large cruisers obsolete, since it was nearly as fast as any of these ships. Consequently, the Royal Navy built a series of ships it called battle cruisers. These were as large as the newest battleships and were armed with battleship guns, but they were much faster (initially a top speed of 25 knots, compared with the 21 knots of battleships). The first was HMS *Invincible,* completed in 1907. Many of these ships were built: 10 for the Royal Navy before 1914, seven for Germany, and four for Japan.

The strength and weakness of battle cruisers

Battle cruisers gained their superior speed by sacrificing heavy armour; as a consequence, they could not stand up to battleships. This was proved at the Battle of Jutland, where the *Invincible* was blown in two by a single salvo and sunk along with two other battle cruisers. These losses led many to argue that the battle cruiser was a mistake, but during the war Britain laid down six more, three of which were eventually completed. The last of them, HMS *Hood,* launched in 1918, could be described as a new stage in warship development. It was so large, at 41,200 tons, that it could combine contemporary battleship armour and armament (equivalent to that of HMS *Queen Elizabeth*) with the very high speed of 31 knots. Although classed as a battle cruiser, it was actually the first of a new generation of very fast battleships.

At the other end of the cruiser spectrum were small, fast "scout" cruisers used for reconnaissance and escort duties. These ships displaced from 3,000 to 7,000 tons and, by 1915, attained speeds as high as 30 knots. They were armed with guns of smaller calibre, usually six or 7.5 inches. The British built many of this type of cruiser, as well as larger types that were nevertheless smaller than their battle cruisers.

Destroyers. The self-propelled torpedo had its greatest impact on the design of small surface ships. Beginning in the 1880s, many nations built hundreds of small steam torpedo boats on the theory that they could bar coastal waters to any enemy. Because their hulls could be crammed with machinery, torpedo boats were quite fast. By the early 1890s, speeds as high as 25 knots were being reported. As a defense against this new fast threat, Britain deployed oversized torpedo boats, calling them torpedo boat destroyers. These craft were successful in hunting down torpedo boats, and eventually they were renamed destroyers.

The first destroyers were essentially coastal craft, displacing only about 200 tons, but their larger successors could accompany battle fleets to sea. There it soon became apparent that a destroyer was in effect a superior sort of torpedo boat, capable of delivering its weapon against capital ships during or immediately after a fleet engagement. By 1914, 800- or even 1,000-ton ships were quite common.

During World War I British destroyer design changed radically, creating what became the postwar formula of the V and W destroyer classes: four four-inch guns superimposed fore and aft, a high forecastle forward for greater seakeeping ability, and two sets of twin (later triple) torpedo tubes amidships. These vessels, displacing about 1,200 tons and capable of 34 knots, made all earlier British destroyers obsolete.

Convoy protection

When Germany adopted unrestricted submarine warfare in February 1917, shipping losses soon forced the diversion of destroyers from fleet duty to convoy protection and antisubmarine warfare. Destroyers were not ideally suited to the escort role, as they had limited steaming range and their high-speed design made them less seaworthy than the merchant ships they were required to escort. The Royal Navy therefore built several types of specialized convoy escort, but the U.S. Navy found it easier to mass-produce its current destroyer design. These vessels, equipped with hydrophones and depth charges, as well as guns and torpedoes, overcame the submarine threat and had a large share in the safe convoy of two million American troops to Europe without loss of a single soldier.

THE AGE OF THE AIRCRAFT CARRIER

Although naval strategists continued to extol the battleship and battle cruiser after World War I, these capital ships soon were swept away by the new art of naval aviation. Conventional naval guns were limited to a range of perhaps 20 miles, but by World War II the aircraft carrier—a ship capable of launching, recovering, and storing aircraft that could themselves destroy ships—had extended the battle range of surface fleets by as much as 300 miles. In doing so, it had a profound effect on naval warfare.

The last capital ships. In 1922 the Five-Power Naval Limitation Treaty, signed in Washington, D.C., by emissaries of the victorious Allies of World War I plus Japan,

changed the character of navies by limiting battleship inventories. With a few exceptions, new battleship construction was prohibited until 1931, and most remaining pre-dreadnought battleships were ordered scrapped. The new battleships allowed by the treaty could not mount guns of greater calibre than 16 inches, and they could not displace more than 35,000 tons.

Battleships were defined as warships armed primarily with guns over eight inches in calibre or displacing more than 10,000 tons. This definition of a battleship in effect defined a new kind of cruiser, which would displace about 10,000 tons and would be armed with eight-inch guns. In 1930 a new treaty, signed in London, extended the battleship-building "holiday" through 1936 and divided cruisers into two classes: ships armed with guns of up to 6.1 inches and ships armed with guns of 6.1 to eight inches. In U.S. parlance the former were light, and the . latter heavy, cruisers.

One peculiarity of the Washington Treaty was that it defined warship size by devising new "standard" tonnages, which excluded the weight of fuel and reserve feed water. (Standard tonnage remains a means of measuring ship displacement in many cases, and it is used here when ship tonnages are listed.) The effect of the London Treaty's limit on cruiser tonnage was the saving of weight in warship design. Several navies used aluminum in structures not contributing directly to the strength of their ships, and there was considerable interest in welding (which was lighter than riveting) and in more efficient hull structures. Lighter machinery was also developed. The U.S. Navy, for example, built higher-pressure, higher-temperature boilers and more efficient turbines.

Most of the battleships that survived the scrappings were rebuilt during the 1920s and '30s with added deck armour and with new blisters to improve their resistance to underwater explosions. In many cases, lighter engines and boilers were fitted, so that weight and internal volume were freed for other purposes such as improved fire-control computers.

New battleships were also built. The Treaty of Versailles limited Germany to 10,000-ton capital ships, but in the 1930s that country built three large cruisers of about 12,000 tons, each armed with six 11-inch guns. These so-called pocket battleships, by combining heavy armour with great speed (provided by diesel engines), could defeat any contemporary cruiser. They also reignited the race in battleship construction. In 1935 France produced the *Dunkerque;* at 26,500 tons, armed with eight 13-inch guns, and reaching 30 knots, this was the first of the new generation of "fast battleships" presaged by HMS *Hood.* In 1937, after the Washington and London treaties had expired, Japan laid down the *Yamato* and *Musashi.* These two 72,800-ton ships, armed with 18.1-inch guns, were the largest battleships in history.

As World War II began, Britain was constructing five battleships of the King George V class. These displaced about 36,000 tons and carried 14-inch guns. The United States completed five 35,000-ton battleships before entering the war and one in 1942, and four 45,000-ton Iowa-class ships were built during wartime. The Iowa ships, carrying 16-inch guns, were the last battleships constructed in the United States. Germany completed five ships (including the 42,000-ton *Bismarck* and *Tirpitz* and the 32,000-ton *Scharnhorst*), France completed four, Italy completed three, and Japan completed two. Most of these fast battleships could exceed 30 knots.

Before the war began, the new arts of dive-bombing and torpedo-bombing from carrier-based aircraft did not promise enough velocity and destructive power to penetrate battleship armour. But by the end of the war, even modern capital ships maneuvering at sea could be sunk by carrier aircraft. In October 1944 and April 1945, U.S. carrier-based airplanes sank the *Musashi* and *Yamato;* more than any other event, these marked the end of the long reign of the battleship.

Aircraft carriers.   *World War I.* The airplane had just begun to go to sea on the eve of World War I. In November 1910 the American scout cruiser USS *Birmingham* launched the first airplane ever to take off from a ship,

and two months later a plane was landed on an improvised flight deck built onto the armoured cruiser USS *Pennsylvania.* In 1913 a British cruiser, HMS *Hermes,* was converted to carry aircraft. In 1916, flying-off decks were built aboard several British ships, and by 1918 the Royal Navy had a converted passenger liner, HMS *Argus,* that could land and launch planes on a flight deck extending from bow to stern. The *Argus* was the world's first true through-deck aircraft carrier and was thus the prototype for all later carriers.

The first
true
aircraft
carrier

Aircraft carriers were valuable in World War I primarily because their planes vastly extended a ship's ability to scout, or reconnoitre, large areas of ocean. The wartime Royal Navy developed a series of torpedo-carrying seaplanes and carrier-based light bombers, but both the aircraft and their weapons were too weak to pose a serious threat. For this reason, the aircraft carrier was considered an essential element of the fleet but not a replacement of the battleship.

Improvements between the wars.   Throughout the interwar period, naval aircraft performance gradually improved, and dive bombers and torpedo bombers made aircraft carriers effective ship killers. In the opinion of many experts, this made other carriers so vulnerable that the only way to protect them was to find and destroy the enemy's carriers first. Another option was to protect the carrier with its own fighters. This option was not practical without some means of detecting an enemy air attack at a great distance, so that defending fighters could be sent up in time. The key to such a defense was radar. The phenomenon of radar was observed in the 1920s, and by the late 1930s prototype sets with huge antennas were operating. Radar was first installed aboard British and U.S. carriers in 1940–41.

As another defensive measure, in 1936 the Royal Navy decided to provide its new carriers with armoured hangars, the armour including part of the flight deck. The U.S. Navy, on the other hand, built its flight decks of wood, on the theory that damage from bombs to the decks could be repaired relatively easily. (Substantial armour lower in the ships was intended to preserve them from more serious bomb damage.)

Aircraft carrier operation required three elements: a means of launching from the ship, a means of recovering aircraft aboard ship, and a means of stowage. Landing aircraft were caught by arresting wires strung across the deck that engaged a hook fastened under the planes' tails. Originally, arresting wires were needed to keep the very light wood-and-cloth airplanes of the World War I era from being blown overboard by gusts of wind. After heavier steel-framed and steel-skinned airplanes were introduced, wires were no longer necessary. The Royal Navy abandoned arresting gear about 1926. The U.S. and Japanese navies continued to use it, but for a very different purpose: to keep landing airplanes from rolling into aircraft that were stowed at the forward end of the flight deck. In British practice this was unnecessary, because aircraft were stowed below immediately upon landing, so that each pilot faced a clear deck when he landed. Stowage was accomplished by elevator lifts, which were usually located in two or three places along the centreline of the flight deck.

World War II.   The Washington Treaty of 1922 permitted each of the major powers to convert two capital ships to carriers, within a 33,000-ton limit. New carriers could not displace more than 27,000 tons, and no carrier could have guns of more than eight inches. The United States and Japan converted heavy battle cruisers just under construction into the USS *Lexington* and *Saratoga* and the Japanese *Akagi* and *Kaga.* These ships actually exceeded the 33,000-ton limit, the U.S. vessels carrying about 80 aircraft and the Japanese about 40. Two new U.S. carriers built in the 1930s to treaty specifications were the *Yorktown* and *Enterprise,* which displaced more than 20,000 tons and carried about 80 aircraft. Their Japanese equivalents were the *Hiryu* and *Soryu,* which operated about 50 aircraft. Britain, which had suspended new capital-ship construction during the war, converted two light battle cruisers completed in 1916, HMS *Courageous* and *Glorious.* For economic reasons Britain did not build a new

The new
"treaty"
warships

carrier to the treaty specifications until 1935, when HMS *Ark Royal* was laid down.

Under a new treaty of 1936, new carriers were limited to 23,000 tons, but the limit on the total number of carriers was removed. In response, the Royal Navy laid down the Illustrious class of 23,000-ton carriers. These vessels did not enter service until after the outbreak of World War II in 1939. With the commencement of war, the United States produced the 27,500-ton Essex class. Carrying more than 100 aircraft, these vessels became the principal fleet carriers of the Pacific Theatre (see Figure 31). Between 1940 and 1943, the United States also designed a series of 45,000-ton ships partly inspired by Britain's Illustrious carriers. Completed after the war ended in 1945, this Midway class was the first of the U.S. carriers to be built with armoured flight decks.

During the war Britain built second-line carriers, called light fleet carriers, which were designed for quick construction. These became the Colossus and Majestic classes, vessels of approximately 15,000 tons that carried about 40 aircraft each. The U.S. war program, meanwhile, included the conversion of a series of cruisers into light carriers of the 11,000-ton Independence class.

For protecting merchant convoys from submarine attack, escort carriers were built in large numbers, mainly in the United States. Many were converted merchant ships, and others were specially built on hulls originally designed for merchant service. The Royal Navy also added flight decks to some tankers and grain carriers, without eliminating their cargo role. These were called MAC ships, or merchant aircraft carriers.

Carriers played a dominant role in every aspect of operations at sea in World War II. The Pacific conflict began with the Japanese carrier strike against Pearl Harbor and ended with American and British carriers operating with impunity against the Japanese homeland. In between, the Battle of the Coral Sea, in May 1942, was the first naval battle in history in which opposing fleets fought without ever coming in sight of each other. A month later off Midway atoll, carriers again played the decisive role. The Battle of Midway reinforced a conviction already clear, especially from British operations in the Mediterranean with and without air support, that control of the sea also meant control of the air over the sea. In the autumn of 1942 the Solomon Islands campaign underlined the importance of both aircraft and submarines in fleet operations, emphasizing that modern sea power was a trident of air, surface, and undersea forces.

Destroyers and escort ships. Most destroyers built between the two world wars repeated Britain's V and W formula, sometimes with more powerful guns or with more torpedo tubes and generally displacing from 1,300 to 1,500 tons. The London Treaty of 1930 prohibited destroyers larger than 1,500 tons, but by the late 1930s several navies had exceeded the limits.

Besides delivering a bomb with enough velocity to damage a capital ship, the dive bomber forced the addition shipboard of large numbers of automatic guns, of 40 millimetres or less, to supplement the more powerful but slower-firing three- to five-inch antiaircraft guns. The Royal Navy converted some of its small World War I cruisers into antiaircraft ships, replacing their single six-inch guns with twin four-inch weapons controlled by special antiaircraft directors. The Japanese built large destroyers (the Akitsuki class) for much the same role; these were armed with a special 3.9-inch gun. The U.S. Navy provided virtually all of its destroyers with effective antiaircraft guns.

As in World War I, destroyers were used for convoy escort against submarines, if only because they were available in large numbers. However, they were not especially suited to that purpose; like their pre-1914 forebears, they were still primarily fast fleet escorts optimized to deal with surface torpedo attack. The likelihood of such attack declined as radar became widely available, but aircraft remained an important threat to major fleet units, so that the destroyer naturally evolved into an antiaircraft escort.

One important exception to the general abandonment of surface torpedo attack was the Imperial Japanese Navy. By 1941 Japanese doctrine envisaged concentrated night attacks by cruisers and destroyers carrying large numbers of unusually powerful, oxygen-fueled, wakeless torpedoes. These torpedoes were the Type 93 Long Lances, which proved extremely effective in the U.S.-Japanese naval battles around the Solomon Islands in 1942–43.

The submarine threat in World War II placed Britain, the United States, and Japan in desperate need of escorts for merchant convoys. Besides converting existing destroyers, each navy built huge numbers of specialized escorts adapted to mass-production techniques. Britain led in these measures, building relatively small escorts of limited endurance, which it called corvettes, and much larger escorts, which it called frigates. The U.S. Navy built a somewhat faster equivalent, which it called a destroyer escort. The Japanese built a series of escorts roughly equivalent to the British corvettes.

Torpedo boats. In the 1930s the German, Italian, British, and U.S. navies regained interest in motor torpedo boats, which had been largely discarded after World War I. All four navies built them in substantial numbers to fight in narrow seas during World War II. Against convoys in the English Channel and the North Sea, the Germans used their S-boats (*Schnellboote,* "fast boats"; often called E-boats by the British). The U.S. Navy's PT (Patrol Torpedo) boats harassed Japanese traffic in the South Pacific. Some of these wooden-hulled craft, which were powered by diesel or gasoline engines, could reach speeds of 40 knots. In addition to torpedoes, they could carry significant gun armament.

Amphibians. The internal combustion engine made

Naval aircraft at the Coral Sea and Midway

The new escort frigates

Figure 31: *USS Lexington, Essex-class aircraft carrier of the U.S. Navy.* A TBF Avenger torpedo bomber lands over the stern; parked at the other end of the 875-foot flight deck are F6F Hellcats. Named for an earlier carrier sunk in the Pacific, in 1944 the *Lexington* took part in the battles of the Philippine Sea and Leyte Gulf. During the latter battle its planes helped sink the Japanese battleship *Musashi.*

possible the most spectacular naval innovation of World War II, the shallow-draft landing craft used to bring large forces quickly to enemy beaches during amphibious assaults. The most famous example of these was the LST (landing ship, tank), a large beaching craft that could embark and disembark troops and vehicles directly from shore to shore. The LST displaced about 4,000 tons full load and transported about 150 troops with equipment at 10 knots.

A beaching craft of intermediate size, which the U.S. Navy called the LCT (landing craft, tank), was carried over oceanic distances and launched at the time of assault. The LCT was too large to fit the davit of a conventional transport, so a new type of ship, the LSD (landing ship, dock), was created specifically to carry it. The LSD had a floodable well deck aft, like a miniature dry dock. It could carry tank-laden LCTs over oceanic distances then flood its well deck off a landing beach and launch the craft.

Not all of these vessels were powered by internal combustion engines; some LSTs and many LSDs used steam. Nevertheless, the vital smaller craft, such as the LCTs and a series of small infantry carriers called LCVPs (landing craft, vehicle, personnel), could not have been built without using diesel power plants. Only because their engines and fuel consumed so small a portion of their total displacement could these craft carry such massive loads on shallow drafts.

THE AGE OF THE GUIDED MISSILE

By the middle of World War II, carrier-borne aircraft had become so effective that the aircraft carrier was clearly replacing the battleship as the core of the modern navy. After the war, the development of jet aircraft and nuclear-powered ship propulsion magnified the range and speed of operations, but they did not alter the central role of the carrier.

The new threat to capital ships

At the same time, though, a new equalizer was being developed: the antiship guided missile. This weapon, which could be mounted onto the smallest surface vessels as well as aircraft and submarines, was especially dangerous to aircraft carriers because it could be launched outside antiaircraft range and, being unmanned, could not be distracted easily by defensive fire. The main defense was to provide the fleet with its own guided missiles capable of destroying either the missile or its launching platform.

Propulsion. *Nuclear power.* The ultimate development in steam propulsion was the use of the energy released by nuclear fission to heat the boilers of steam turbines. Nuclear power was proposed for ships, particularly submarines, in 1945, and by 1955 the United States had a nuclear submarine, USS *Nautilus*, in service. Other navies followed suit, so that within 20 years Britain, the Soviet Union, France, and China all operated nuclear submarines. In the 1950s the United States also developed nuclear power plants for surface ships, subsequently installing them aboard aircraft carriers and their escorts. The Soviet Union and France followed with more limited programs in the 1970s and '80s.

For a surface ship, the advantage of nuclear power was effectively infinite range at high speed. The disadvantage was the high cost, which limited such power to a few valuable ships.

Gas turbines. After 1945 the gas turbine, a turbine in which the combustion of fuel generates a stream of gases that turns the rotor, became available for ship propulsion. Gas turbines shared with internal combustion piston engines the great virtues of quick starting and stopping as well as relatively simple operation. They were also quite reliable. Their main defect was that they were efficient only over a relatively narrow speed range. For this reason, the first gas turbine warships employed combination power plants, such as combined steam and gas turbine (COSAG) or combined diesel and gas turbine (CODAG). Using such a plant, a relatively small ship, such as a frigate, could achieve much higher speed than with a conventional steam turbine. The next step was to combine two gas turbines, one sized for cruising and the other for high speed. Such an arrangement might be either combined gas and gas (COGAG), with both plants able to operate together,

or combined gas or gas (COGOG), with only one plant being used at a time.

Systems employing the gas turbine proved useful in smaller escort ships such as destroyers and frigates, although they were also installed in cruiser-sized vessels. A related system, called combined diesel, electric, and gas turbine (CODLAG), was especially valuable in submarine warfare. In order to minimize engine noise, which might interfere with sonar sensors, diesel generators powered electric motors, which in turn drove the ship's propellers. For higher speeds, electricity was supplemented or replaced by gas turbines.

Armour. The role of armour greatly declined after 1945 because aircraft, the greatest threat to warships, now carried guided missiles and bombs capable of penetrating the thickest deck armour that any viable ship could accommodate. At the same time, warships' new missile weaponry occupied much more space than did the earlier guns, shells, and powder. Modern weapon systems also required room for computers and radars and for their operators. To cover such spaces with anything but the lightest plating would have added enormous weight and thus required very large and expensive hulls. The high cost of protection (in ship size as well as money) was a major reason for the abandonment of heavy, extensive armour in the guided-missile era.

The abandonment of heavy armour

Armour was not abandoned altogether, however. Thin armour, for example, could protect aircraft and missiles from the steel splinters of exploding warheads and thus could keep a ship hit elsewhere from being destroyed by a huge explosion of jet fuel or its own missiles. For this reason most modern warships adopted thin (about one- or two-inch) splinter protection around their missile magazines.

Aircraft carriers, at least in the U.S. Navy, retained armoured flight decks, though in their case the armour provided structural strength as well as limited protection.

Aircraft carriers. After World War II the heavy attack aircraft carrier developed three roles: to deliver air strikes (both conventional and nuclear) against sea and shore targets; to provide a long-range air-defense umbrella for other ships; and to support antisubmarine operations (leaving it to other ships actually to destroy the submarines). In order to carry out these three roles, jet carriers became so huge that only a first-rate power could afford to build and operate them. Within 35 years of the end of World War II, only the United States and France operated full-scale carriers (although the 27,000-ton French Clemenceau class was closer in size to the World War II Essex carriers than to the 80,000-ton, 1,000-foot behemoths built by the United States in the 1970s and '80s). The Soviet Union began to build large carriers in 1983.

Navies that could not afford the large carrier divided its three roles among escort ships and new light aircraft carriers. To the light aircraft carriers was given the role of antisubmarine warfare, along with limited ground-attack and air-protection capabilities.

Large carriers. The main wartime technical development in aircraft carrier design was the hydraulic catapult, but this was barely powerful enough to launch the heavier jet aircraft coming into service after 1945. The problem was solved in 1951, when the British first tested an effective catapult driven by steam from a ship's boilers.

Jet aircraft landed at much higher speeds than had propeller-driven planes, making the installation of better arresting gear necessary. Also, landing control had to be improved, because the approaching pilot had to make crucial decisions much more quickly. As in the case of the steam catapult, the British supplied the solution, in the form of the angled deck and the mirror (later the Fresnel-lens) landing sight. By building an extension of the flight deck to one side and angling the landing strip onto that extension, the British system allowed a pilot to land away from aircraft parked at the end of the flight deck. If he missed the arresting wires, the pilot could fly off to try again. In this way mistakes became much less serious.

The angled flight deck

The mirror landing sight, in effect, allowed the pilot to see his own position relative to the required glide path and to make corrections instantly. Previously, an officer

on deck, observing the landing, had generally ordered the corrections.

By 1955 the modern jet aircraft carrier had emerged, with steam catapults, an angled deck, and a mirror landing system. The first full jet carrier was USS *Forrestal,* commissioned in 1955. The 60,000-ton Forrestal carriers were built with rectangular extensions to the after part of the flight deck; these considerably widened the deck and allowed the angled landing strip to be merely painted on rather than extended over the side. The elevators were shifted to the edge of the flight deck, so that they could operate while aircraft were landing and taking off.

The first nuclear-powered carrier, USS *Enterprise,* was commissioned in 1961. It was equipped with eight nuclear reactors and steamed for more than three years before refueling was necessary. The *Enterprise* displaced 75,700 tons, carried 100 jet aircraft, and could reach more than 30 knots. Beginning in 1975, the Nimitz class superseded the *Enterprise.* These 81,600-ton carriers were powered by only two nuclear reactors, yet they reached speeds comparable to the *Enterprise,* and their uranium cores needed replacement only once every 13 years. The smaller propulsion system created more room for the storage of aviation fuel, which greatly extended the operation of the 90 aircraft carried on these ships.

In 1983 the Soviet Union laid down a 65,000-ton nuclear-powered carrier, and in 1989 France laid down the 34,000-ton *Charles de Gaulle,* a nuclear-powered ship designed to carry 40 aircraft.

Light carriers. The expense of large carriers was due partly to the huge amounts of fuel, ammunition, and maintenance required to keep as many as 80 aircraft operational, but it was also due to the complexity and size of the catapults and arresting gear needed for jets. In the late 1960s Britain developed a jet fighter, the Harrier, that was capable of taking off vertically or (with a heavy payload) after a short roll. A carrier equipped with these V/STOL (vertical/short takeoff and landing) jets could be much smaller than a full jet carrier, because it would need neither catapults nor arresting gear. In the 1970s and '80s, Britain built three such ships, constituting the Invincible class. These 20,000-ton ships carried eight Sea Harriers and about a dozen antisubmarine helicopters. They also incorporated a further British contribution to aircraft carrier design: the upward-sloping "ski jump" at the end of the flight deck to assist the Sea Harriers in short takeoff.

> V/STOL jets and the "ski-jump" flight deck

The Italian and Spanish navies also constructed light carriers for helicopters and V/STOL jets. Like the Invincibles, they were powered by gas turbines. The Soviet Kiev class, at more than 30,000 tons, carried a larger complement of rotary and V/STOL craft.

In the 1960s, '70s, and '80s the United States constructed the Iwo Jima, Tarawa, and Wasp classes of amphibious assault ships, descendants of the World War II escort carriers that could transport close to 2,000 marines as well as their weapons and vehicles. The Tarawa and Wasp classes, besides carrying helicopters and Harriers, were built with well decks for the launching of landing craft.

Occupying a position between cruisers and the through-deck light carriers were helicopter carriers, whose flight decks occupied only the after section of the ship. The 17,000-ton Moskva class of the Soviet Union, introduced in 1967, was a prominent example.

Fleet escort ships. In the surface ships supporting aircraft carriers, the most important trend after 1945 was an amalgamation of types. In 1945 cruisers were armoured big-gun ships that were capable of operating independently for protracted periods. Destroyers were part of the screen protecting a main fleet, and frigates were slower ships designed for merchant convoy protection against air and submarine threats—primarily the latter.

This series of distinctions began to collapse in the late 1950s. First, in order to hunt the new fast submarines, frigates had to match destroyer speeds. This made them more like small destroyers. At the same time, most cruisers were converted to carry long-range antiaircraft missiles. This conversion made it clear that cruisers were not solitary raiders or ship killers but fleet escorts—in effect, super destroyers. Eventually all three types became capable of

antiaircraft, antisubmarine, and antiship warfare, although individual classes often specialized in one role.

The most prominent trend in armament was a shift from guns to guided missiles. Beginning in the mid-1950s, existing ships had at least some of their guns replaced by missiles, and thereafter new ships were built with missiles making up their main batteries. By 1990 the ranges of these weapons varied from about four nautical miles for a short-range antimissile missile to more than 300 nautical miles for a long-range antiship missile. Some of these traveled at more than twice the speed of sound.

> From gun to missile

Main guns became fewer and smaller. By 1990 the most prominent guns were dual-purpose weapons (for antiaircraft as well as surface fire) measuring from 76 to 130 millimetres, or three to five inches. Close-in protection against missiles was provided by fully automatic or Gatling-type guns of 20 to 40 millimetres. All guns were now remotely controlled and directed by radar.

Cruisers. The era of big-gun cruisers ended with the completion of ships laid down during World War II. In 1961 the United States commissioned USS *Long Beach,* the first vessel designed from the keel up as a guided-missile cruiser and the first surface warship to steam under atomic energy. This 14,000-ton ship was followed by a series of nuclear-powered U.S. cruisers that ended, in the 1970s, with the 10,400-ton Virginia class. This class was supplemented in the 1980s by the 7,400-ton, gas-turbine-powered Ticonderoga cruisers. Both the Virginia and Ticonderoga ships were fitted with a broad array of weaponry, including surface-to-air and antiship missiles, tube-launched and rocket-launched antisubmarine torpedoes, and two five-inch and two 20-millimetre guns. In addition, they were supplied with Tomahawk cruise missiles, which could be fitted with conventional or nuclear warheads. The Ticonderoga vessels carried two submarine-hunting helicopters, and they were equipped with the extremely sophisticated Aegis radar system for tracking hostile targets and directing missile defense (see Figure 32).

Department of Defense photo

Figure 32: *USS Ticonderoga, guided-missile cruiser of the U.S. Navy.*
A Standard surface-to-air missile is fired from the aft launcher. Equipped with a phased-array radar system that can guide several missiles simultaneously to their targets, the Ticonderoga class has continued the evolution of cruisers into antiaircraft ships escorting carrier task forces.

As the guided-missile cruiser evolved into an escort for aircraft carriers, it ceased to be built by navies that had allowed their large carrier capacities to expire. Britain, for example, sold its County-class ships (which were officially classed as destroyers but were effectively cruisers) in the 1970s and '80s, relying thereafter on smaller escorts to protect its light carriers. The Soviet Union, on the other hand, laid down the first of its 22,000-ton, nuclear-powered Kirov cruisers in 1973. With armament, speed, and steaming range comparable to the Virginias, these cruisers were logical escorts for the new nuclear-powered aircraft carriers that were expected to give the Soviet Navy the ability to project its power around the world. Until then, Soviet guided-missile cruisers had emphasized a heavy complement of long-range antiship missiles, giving

some of them a ship-killing role similar to that of the big-gun cruisers.

Destroyers and frigates. Because of the high cost of cruisers, smaller escort ships became the backbone of lesser navies in the guided-missile age. The destroyer completed its transition, begun during World War II, from surface-ship killer to antiaircraft escort. To this duty was added antisubmarine warfare, the traditional role of the frigate. Often the latter was distinguished from the destroyer only by its lesser displacement, armament, and speed.

The shift to anti-aircraft escort

As submarines became faster, many classes of destroyer and frigate adopted the helicopter (often housed in a hangar in the after section) as a help in hunting them down. Like cruisers, they bristled with an array of sonar and radar sensors and were packed with electronic gear for the swift detection and identification of hostile targets and the computation of firing data. Such complex equipment, packed into ships that must also have high speed (30 knots and more), excellent seakeeping ability, and long endurance, meant that destroyers and frigates became larger than their World War II predecessors. Guided-missile destroyers ranged from 3,500 to 8,000 tons displacement, while frigates ranged between 1,500 and 4,000 tons.

Amphibians.   The diesel-powered Newport LSTs, which entered service in the U.S. Navy in the 1960s, displaced more than 8,000 tons full load and transported amphibious craft, tanks, and other combat vehicles, along with 400 men, at speeds of up to 20 knots. Instead of merely beaching, like their World War II predecessors, they were fitted with an extendable ramp supported by huge projecting derrick extensions on each side of the bow. As the ship grounded, the ramp would shoot forward hydraulically 112 feet. Vehicles and troops would land over the ramp, while amphibious craft in the tank deck would disembark from stern gates.

The Alligator-class LST was a smaller Soviet equivalent of the Newport.

Beginning in the 1970s, gas-turbine power allowed the deployment of air-cushioned landing craft, which were naval hovercraft that could bring tanks and troops to shore at speeds of about 50 knots.   (N.F.)

Submarines

A submarine is a naval vessel that is capable of propelling itself beneath the water as well as on the water's surface. This is a unique capability among warships, and submarines are quite different in design and appearance from surface ships. Submarines first became a major factor in naval warfare during World War I (1914–18), when Germany employed them to destroy surface merchant vessels. In such attacks submarines used their primary weapon, a self-propelled underwater missile known as a torpedo. Submarines played a similar role on a larger scale in World War II (1939–45), in both the Atlantic (by Germany) and the Pacific (by the United States). In the 1960s the nuclear-powered submarine, capable of remaining underwater for months at a time and of firing long-range nuclear missiles without surfacing, became an important strategic weapon platform. Armed with torpedoes as well as antiship and antisubmarine missiles, the nuclear attack submarine has also become a key element of naval warfare.

Following is a history of the development of submarines from the 17th century to the present. For a history of other warships, see above *Naval ships and craft.* For the weaponry of modern attack and strategic submarines, see above *Tactical guided missiles* and *Strategic missiles.*

EARLY HAND-POWERED SUBMERSIBLES

The first serious discussion of a "submarine"—a craft designed to be navigated underwater—appeared in 1578 from the pen of William Bourne, a British mathematician and writer on naval subjects. Bourne proposed a completely enclosed boat that could be submerged and rowed underwater. It consisted of a wooden frame covered with waterproof leather; it was to be submerged by reducing its volume by contracting the sides through the use of hand vises. Bourne did not actually construct his boat, and Cornelis Drebbel (or Cornelius van Drebel), a Dutch

inventor, is usually credited with building the first submarine. Between 1620 and 1624 he successfully maneuvered his craft at depths of from 12 to 15 feet (four to five metres) beneath the surface during repeated trials in the Thames River, in England. King James I is said to have gone aboard the craft for a short ride. Drebbel's submarine resembled that proposed by Bourne in that its outer hull consisted of greased leather over a wooden frame; oars extended through the sides and, sealed with tight-fitting leather flaps, provided a means of propulsion both on the surface and underwater. Drebbel's first craft was followed by two larger ones built on the same principle.

A number of submarine boats were conceived in the early years of the 18th century. By 1727 no fewer than 14 types had been patented in England alone. In 1747 an unidentified inventor proposed an ingenious method of submerging and returning to the surface: his submarine design had goatskin bags attached to the hull with each skin connected to an aperture in the bottom of the craft. He planned to submerge the vessel by filling the skins with water and to surface by forcing the water out of the skins with a "twisting rod." This arrangement was a forerunner of the modern submarine ballast tank.

The submarine was first used as an offensive weapon in naval warfare during the American Revolution (1775–83). The *Turtle*, a one-man craft invented by David Bushnell, a student at Yale, was built of wood in the shape of a walnut standing on end (see Figure 33). Submerged, the craft was powered by propellers cranked by the operator. The plan was to have the *Turtle* make an underwater approach to a British warship, attach a charge of gunpowder to the ship's hull by a screw device operated from within the craft, and leave before the charge was exploded by a time fuse. In the actual attack, however, the *Turtle* was unable to force the screw through the copper sheathing on the warship's hull.

Bushnell's *Turtle*

Robert Fulton, famed U.S. inventor and artist, experimented with submarines several years before his steamboat *Clermont* steamed up the Hudson River. In 1800, while in France, Fulton built the submarine *Nautilus* under a grant from Napoleon Bonaparte. Completed in May 1801, this craft was made of copper sheets over iron ribs. A collapsing mast and sail were provided for surface propulsion, and a hand-turned propeller drove the boat when submerged. A precursor of a conning tower fitted with a glass-covered porthole permitted observation from within the craft. The *Nautilus* submerged by taking water into ballast tanks, and a horizontal "rudder"—a forerunner of the diving

Figure 33: Bushnell's submarine torpedo boat, 1776. Drawing of a cutaway view made by Lieutenant Commander F.M. Barber in 1885 from a description left by Bushnell.

plane—helped keep the craft at the desired depth. The submarine contained enough air to keep four men alive and two candles burning for three hours underwater; later a tank of compressed air was added.

The *Nautilus* was intended to attach an explosive charge to the hull of an enemy ship in much the same manner as the *Turtle.* Fulton experimentally sank an old schooner moored at Brest but, setting out to destroy British warships, was unable to overtake those he sighted. France's interest in Fulton's submarine waned, and he left for England, offering his invention to his former enemy. In 1805 the *Nautilus* sank the brig *Dorothy* in a test, but the Royal Navy would not back his efforts. Fulton then came to the United States and succeeded in obtaining congressional backing for a more ambitious undersea craft. This new submarine was to carry 100 men and be powered by a steam engine. Fulton died before the craft was actually finished, however, and the submarine, named *Mute,* was left to rot, eventually sinking at its moorings.

During the War of 1812 between the United States and England, a copy of the *Turtle* was built, which attacked HMS *Ramillies* at anchor off New London, Conn. This time the craft's operator succeeded in boring a hole in the ship's copper sheathing, but the screw broke loose as the explosive was being attached to the ship's hull.

The next U.S. attempt at submarine warfare came during the Civil War (1861–65) when the Confederate States resorted to "unconventional" methods to overcome the Union Navy's superior strength, exerted in a blockade of Southern ports. In 1862 Horace L. Hunley of Mobile, Ala., financed the building of a Confederate submarine named *Pioneer,* a craft that was 34 feet long and was driven by a hand-cranked propeller operated by three men. It probably was scuttled to prevent its capture when Union forces occupied New Orleans (although some records say the *Pioneer* was lost with all those aboard during a dive while en route to attack Union ships).

The second submarine developed by the same builders was a remarkably advanced concept: a 25-foot iron boat intended to be propelled by a battery and electric motors. Not surprisingly, no suitable motors could be found, so a propeller cranked by four men was again adopted. The submarine sank without loss of life in heavy seas off Mobile Bay while seeking to attack the enemy.

Con-
federate
submarines

The third submarine of the Confederacy was the *H.L. Hunley,* a modified iron boiler lengthened to between 36 and 40 feet. Ballast tanks and a system of weights submerged the craft; it could travel at a speed of four miles an hour, powered by eight men cranking its propeller. Its armament consisted of a "torpedo," filled with 90 pounds (40 kilograms) of gunpowder, towed behind the submarine at the end of a 200-foot line. The *Hunley* was to dive under an enemy warship and drag the torpedo against its hull. After a successful test against a barge, the *Hunley* was moved by railroad to Charleston, S.C. There the vessel suffered several disasters, sinking three times and drowning a number of crewmen including Hunley himself. Manned for a fourth time, the *Hunley* was fitted with a "torpedo" on the end of a long spar, and the craft made several successful dives. On the night of Feb. 17, 1864, the submarine attacked the Union warship *Housatonic* in Charleston harbour. The torpedo's detonation exploded the warship's magazines: the *Housatonic* sank in shallow water with the loss of five men, but the *Hunley* was also destroyed by the explosion, and its crew was killed.

One of the more intrepid submarine inventors of the same period was Wilhelm Bauer, a noncommissioned officer of Bavarian artillery who built two boats, *Le Plongeur-Marin* (1851) and *Le Diable-Marin* (1855). The first boat sank in Kiel harbour on Feb. 1, 1851, but Bauer and his two assistants escaped from a depth of 60 feet after the craft had been on the bottom for five hours. His second craft, built for the Russian government, was successful and reportedly made 134 dives before being lost at sea. In September 1856, during the coronation of Tsar Alexander II, Bauer submerged his submarine in Kronshtadt harbour with several musicians on board. An underwater rendition of the Russian national anthem was clearly heard by persons inside ships in the harbour.

TOWARD DIESEL-ELECTRIC POWER

A major limitation of the early submarines was their lack of a suitable means of propulsion. In 1880 an English clergyman, George W. Garrett, successfully operated a submarine with steam from a coal-fired boiler that featured a retractable smokestack. The fire had to be extinguished before the craft would submerge (or it would exhaust the air in the submarine), but enough steam remained in the boilers for traveling several miles underwater.

Similarly, the Swedish gun designer Torsten Nordenfelt constructed a steam-powered submarine driven by twin propellers. His craft could be submerged by vertical propellers to a depth of 50 feet and was fitted with one of the first practical torpedo tubes. Several nations built submarines to Nordenfelt's design.

In an effort to overcome the problems of propulsion, two French naval officers built the 146-foot submarine *Le Plongeur* in 1864, powered by an 80-horsepower compressed-air engine, but the craft quickly exhausted its air tanks whenever it got under way. Development of the electric motor finally made electric propulsion practicable. The submarine *Nautilus,* built in 1886 by two Englishmen, was an all-electric craft. This *Nautilus,* propelled by two 50-horsepower electric motors operated from a 100-cell storage battery, achieved a surface speed of six knots (nautical miles per hour; one knot equals 1.15 statute miles per hour or 1.85 kilometres per hour). But the battery had to be recharged and overhauled at short intervals, and the craft was never able to travel more than 80 miles without a battery recharge. In France, Gustave Zédé launched the *Gymnote* in 1888; it, too, was propelled by an electric motor and was extremely maneuverable but tended to go out of control when it dived.

The end of the 19th century was a period of intensive submarine development, and Zédé collaborated in a number of designs sponsored by the French navy. A most successful French undersea craft of the period was the *Narval,* designed by Maxime Laubeuf, a marine engineer in the navy. Launched in 1899, the *Narval* was a double-hulled craft, 111.5 feet long, propelled on the surface by a steam engine and by electric motors when submerged. The ballast tanks were located between the double hulls, a concept still in use today. The *Narval* made a large number of successful dives. Further French progress in submarines was marked by the four Sirène-class steam-driven undersea craft completed in 1900–01 and the *Aigrette,* completed in 1905, the first diesel-driven submarine of any navy.

The
Narval:
steam–
electric
propulsion

Similarly, there were submarine successes in the United States by rival inventors John P. Holland (an Irish immigrant) and Simon Lake. Holland launched his first undersea craft in 1875. This one and its successors were significant in combining water ballast with horizontal rudders for diving. In 1895, in competition with Nordenfelt, Holland received an order from the U.S. Navy for a submarine. This was to be the *Plunger,* propelled by steam on the surface and by electricity when submerged. The craft underwent many design changes and finally was abandoned before completion. Holland returned the funds advanced by the navy and built his next submarine (his sixth) at his own expense. This was the *Holland,* a 53.25-foot craft launched in 1897 and accepted by the navy in 1900. For underwater propulsion the *Holland* had an electric motor, and it was propelled on the surface by a gasoline engine. The submarine's armament consisted of a bow torpedo tube, for which three torpedoes were carried, and two dynamite guns. With its nine-man crew the *Holland* was a successful boat; it was modified many times to test different arrangements of propellers, diving planes, rudders, and other equipment.

Holland's chief competitor, Simon Lake, built his first submarine, the *Argonaut I,* in 1894; it was powered by a gasoline engine and electric motor. This and Lake's other early boats were intended as undersea research craft. In 1898 the *Argonaut I* sailed from Norfolk, Va., to New York City under its own power, predating the cruises of the French *Narval* and marking the first time an undersea craft operated extensively in the open sea. Lake's second submarine was the *Protector,* launched in 1901.

Of the major naval powers at the turn of the century,

The first
U-boat

only Britain remained indifferent toward submarines. Finally, in 1901, the Royal Navy ordered five of the Holland-design undersea craft. Germany completed its first submarine, the *U-1* (for *Unterseeboot 1*), in 1905. This craft was 139 feet long, powered on the surface by a heavy oil engine and by an electric motor when submerged, and was armed with one torpedo tube. Thus, the stage was set for the 20th-century submarine, a craft propelled on the surface by diesel engines and underwater by battery-powered electric motors, submerging by diving planes and taking on water ballast, and armed with torpedoes for sinking enemy ships. The quarters inside these early craft were cramped, generally wet, and stank from diesel oil.

World War I. By the eve of World War I all of the major navies included submarines in their fleets, but these craft were relatively small, were considered of questionable military value, and generally were intended for coastal operations. The most significant exception to the concept of coastal activity was the German Deutschland class of merchant U-boats, each 315 feet long with two large cargo compartments. These submarines could carry 700 tons of cargo at 12- to 13-knot speeds on the surface and at seven knots submerged. The *Deutschland* itself became the *U-155* when fitted with torpedoes and deck guns, and, with seven similar submarines, it served in a combat role during the latter stages of the war. In comparison, the "standard" submarine of World War I measured slightly over 200 feet in length and displaced less than 1,000 tons on the surface.

The prewar submarines generally had been armed with self-propelled torpedoes for attacking enemy ships. During the war submarines also were fitted with deck guns. This permitted them to approach enemy merchant ships on the surface and signal them to stop for searching (an early war policy) and later to sink small or unarmed ships that did not warrant expenditure of torpedoes. Most war-built submarines had one and sometimes two guns of about three- or four-inch calibre; however, several later German submarines carried 150-millimetre guns (including the Deutschland class in military configuration).

An important armament variation was the submarine modified to lay mines during covert missions off an enemy's harbours. The Germans constructed several specialized submarines with vertical mine tubes through their hulls; some U-boats carried 48 mines in addition to their torpedoes.

Anti-
submarine
submarines

Also noteworthy was the development, during the war, of the concept of an antisubmarine submarine. British submarines sank 17 German submarines during the conflict; the early submarine-versus-submarine successes led to British development of the R-class submarine intended specifically for this role. These were relatively small craft, 163 feet long and displacing 410 tons on the surface, with only one propeller (most contemporary submarines had two). Diesel engines could drive them at nine knots on the surface, but once submerged, large batteries permitted their electric motors to drive them underwater at the high speed of 15 knots for two hours. (Ten knots was a common speed for submerged submarines until after World War II.) Thus, they were both maneuverable and fast. Advanced underwater listening equipment (asdic, or sonar) was installed, and six forward torpedo tubes made them potent weapons. Although these submarines appeared too late to have any actual effect on the war, they pioneered a new concept in the development of the submarine.

All World War I-era submarines were propelled by diesels on the surface and by electric motors submerged, except for the British Swordfish and K class. These submarines, intended to operate as scouts for surface warships, required the high speeds then available only from steam turbines. The K-boats steamed at 23.5 knots on the surface, while electric motors gave them a 10-knot submerged speed.

World War II. Interest in submarines continued high within the world's navies during the period between World Wars I and II. Britain, France, and Japan built improved types, and during this period the U.S. Navy built its first large long-range submarine, the *Argonaut*. Completed in 1928, it was 381 feet long, displaced 2,710 tons on the surface, was armed with two six-inch guns and four forward

torpedo tubes, and could carry 60 mines. The *Argonaut,* the largest nonnuclear submarine ever built by the U.S. Navy, led to the highly successful Gato and Balao classes of U.S. submarines used in World War II.

During the 1930s the rejuvenated Soviet shipyards began producing large numbers of submarines, primarily coastal craft, in an attempt to make the Soviet Union a sea power without major expenditures for surface warships. But though the Soviet program achieved quantity, their ships were unsuitable for operations against the German Navy, their crews were poorly trained, and Soviet bases were blocked by ice much of the time.

From J P Mallmann Showell, *U-Boats under the Swastika* (1987)
Figure 34: *Launching of U-218 at Kiel, Ger., in 1941.*
With the exception of mine-laying shafts just behind the conning tower, this Type VIID submarine was essentially identical to the Type VIIC, which hunted Allied ships in the Atlantic during World War II.

Type VII
U-boats

World War II saw extensive submarine campaigns on all of the world's oceans. In the Atlantic the principal German U-boat was the VII type, a relatively small but effective craft when properly employed. The Type VIIC variant was 220.25 feet long, displaced 769 tons on the surface, and was powered by diesel-electric machinery at a speed of 17 knots on the surface and 7.5 knots submerged. Armament consisted of one 90-millimetre deck gun, various antiaircraft guns, and five torpedo tubes, four forward and one aft. Either 14 torpedoes or 14 tube-launched mines were carried. Manned by a crew of 44, these submarines had a surface endurance of 6,500 miles at 12 knots, but, when they were submerged, their batteries would remain active a little less than a day at four knots.

The ultimate diesel-electric submarine evolved in the war was the German Type XXI, a 250-foot, 1,600-ton craft that could attain $17^1/2$ knots submerged for more than an hour, could travel at six knots underwater for two days, or could "creep" at slower speeds for four days. These submarines were fitted with snorkel devices (see below), which made it unnecessary for them to surface fully to recharge their batteries after operating submerged. The Type XXI had an operating depth of 850 feet, more than twice what was then normal, and was armed with four 33-millimetre guns and six forward torpedo tubes (23 torpedoes carried). These properties made all earlier submarines obsolete. Existing Allied antisubmarine forces would have had serious trouble coping with these craft had the war continued past the spring of 1945.

A final German war design of particular interest was the Walter turbine propulsion plant. The need for oxygen for combustion had previously prevented the use of steam turbines or diesels while the submarine was submerged and air was at a premium. Hellmuth Walter, a German scientist, developed a turbine propulsion system using oxygen generated by hydrogen peroxide to operate the turbine while submerged. A simplified submarine, the *V-80,* built in 1940 and propelled by a Walter turbine system, could attain speeds of more than 26 knots submerged for a short period of time. After many delays, the first Walter-

propelled Type XVII combat submarines were completed and could reach 25 knots underwater for brief periods, and a submerged run of 20 knots for $5^1/_2$ hours was achieved on trials. But these submarines, like the Type XXI, were not ready for full-scale operations when the war ended.

The snorkel

A notable German submarine development of World War II was the *schnorchel* device (anglicized by the U.S. Navy to "snorkel"). Its invention is credited to a Dutch officer, Lieutenant Jan J. Wichers, who in 1933 advanced the idea of a breathing tube to supply fresh air to a submarine's diesel engines while it was running submerged. The Netherlands Navy began using snorkels in 1936, and some fell into German hands in 1940. With the advent of radar to detect surfaced submarines, the Germans fitted hundreds of U-boats with snorkels to permit the operation of diesels at periscope depth (to recharge batteries for underwater propulsion) with less of a possibility of detection by Allied radar-equipped ships and aircraft.

In the Pacific war the Japanese employed a large number of submarines of various sizes and types, including aircraft-carrying submarines, midget submarines, and "human torpedoes" carried by larger submarines. The Japanese I-201 class was a high-speed submarine, of 259 feet and 1,291 tons displacement, that had diesel propulsion for 15 knots on the surface; while underwater, large batteries and electric motors could drive the vessel at a speed of 19 knots for almost one hour. Each boat had two 25-millimetre guns and four forward torpedo tubes and carried ten torpedoes.

U.S. submarines

The highly successful U.S. submarine campaign in the Pacific war was waged mainly with the Gato- and Balao-class submarines. These were approximately 311.5 feet long, displaced 1,525 tons, and had diesel-electric machinery for 20-knot surface and nine-knot underwater speeds. The principal difference between the two designs was the 300-foot operating depth for the Gato class and 400-foot depth for the Balao boats. Manned by 65 to 70, these submarines had one or two five-inch deck guns plus smaller antiaircraft weapons and 10 torpedo tubes (six forward, four aft) and carried 24 torpedoes.

Postwar developments. After the war the Allies were quick to adopt advanced German submarine technology. The British built two peroxide turbine-propelled experimental submarines, but this concept lost favour because of the unstable properties of hydrogen peroxide and because of American success with nuclear propulsion. The Soviet Union began building modifications of the Type XXI submarine. Some 265 of these submarines, labeled Whiskey and Zulu class by NATO observers, were completed between 1950 and 1958, more submarines than built by all of the world's other navies combined between 1945 and 1970. (In that period Soviet shipyards produced a total of 560 new submarines.)

The U.S. Navy studied German technology and converted 52 war-built submarines to the Guppy configuration (an acronym for greater underwater propulsive power with the "y" added for phonetics). These submarines had their deck guns removed and streamlined conning towers fitted; larger batteries and a snorkel were installed; four torpedoes and, in some craft, one of the four diesel engines were removed. The result was an underwater speed of 15 knots and increased underwater endurance.   (N.C.P./Ed.)

Although the major powers switched to nuclear power after World War II, the great bulk of the world's navies continued to buy—or in a few cases, build—submarines descended directly from the fast diesel-electric U-boats of the war. (Indeed, many of them were designed and built in West Germany.) The main advances were in weapons and sensors. Deck guns were abandoned, in some cases for antiship missiles. Torpedoes, which soon could exceed 50 knots, either homed onto their targets acoustically with self-contained sonar or were guided by electronic commands passed to them through a threadlike wire paid out behind the speeding projectile. Submarine sonars, for detecting both surface ships and other submarines, were enormously improved.

Improved underwater endurance

On the other hand, maximum submerged speed increased only somewhat (to more than 20 knots) over the German Type XXI, and endurance at top speed was no greater than at the end of World War II. Improvements in bat-

tery design concentrated more on increasing endurance at low speed. Some modern submarines, for example, could remain submerged (at about three knots) for as long as a week to 10 days. That was an important improvement, since during so long a period sea conditions could easily arise that would allow a submarine to escape or force submarine hunters on the surface to disperse.

Postwar diesel-electric submarines continued to be equipped with snorkels, but hunters adopted improved radars that could detect even the small head of the snorkel, just as aircraft with more primitive radars could detect surfaced U-boats during World War II.

For these reasons, diesel-electric submarines remained furtive platforms, conserving their energy for the postattack escape. Because their electric motors were quieter than nuclear units (and could even be shut off for a time), they were sometimes proposed as antisubmarine ambushers that would silently await their prey in areas through which enemy submarines were known to pass. Britain's Upholder class, 230 feet long and displacing about 2,000 tons at the surface, was built in the 1980s to operate in this capacity alongside nuclear vessels.

NUCLEAR PROPULSION

In 1954, with the commissioning of USS *Nautilus,* nuclear power became available. Since the nuclear reactor needed no oxygen at all, a single power plant could now suffice for both surface and submerged operation. Moreover, since a very small quantity of nuclear fuel (enriched uranium) provided power over a very long period, a nuclear submarine could operate completely submerged at high speed indefinitely.

This change was revolutionary. In the typical prenuclear submarine attack, the submarine approached the target on the surface to avoid draining the battery and submerged only just before coming within sight of the target. The submerged approach had to be made at very low speed, perhaps no more than two or three knots, again to avoid wasting battery power. The submarine commander had to husband his battery charge until after the attack, when he would have to use full underwater power (and a speed of perhaps seven to 10 knots) to evade the counterattack. Even then, a full battery charge would last only about one or two hours at top speed. This necessity of conserving battery power, which forced diesel-electric submarines to approach their targets as quietly and slowly as possible, meant that they could not engage most fast surface warships, such as aircraft carriers and battleships.

Operating freely underwater

Nuclear submarines were in an altogether different class. Not only could they evade freely (that is, at top speed for indefinite periods) after attacking, they could also operate freely before attacking and keep up with fast surface ships. This principle was illustrated by the only instance of a nuclear submarine's firing of a weapon in anger. During the Falkland Islands conflict in 1982, a British nuclear submarine, HMS *Conqueror,* followed the fast Argentine cruiser *General Belgrano* for more than 48 hours before closing in to sink it. That performance would have been entirely beyond the capability of any prenuclear submarine. For the first time, a submarine commander could maneuver freely underwater, without worrying that he was exhausting his vessel's batteries, and fast surface warships were vulnerable to submarine attack.

Initially, the major powers continued to build diesel-electric submarines alongside nuclear vessels, but some later gave in to the expense of maintaining two categories of submarine in parallel. After 1959 the U.S. Navy effectively ceased construction of nonnuclear submarines. The Royal Navy, which completed its first nuclear submarine, HMS *Dreadnought,* in 1963, followed a similar policy until the 1980s, when it began the Upholder class. France completed its first nuclear submarine, *Le Redoutable,* in 1971 and effectively abandoned diesel-electric construction in 1976. Although the Soviets continued to build diesel submarines, the bulk of their new construction shifted to nuclear power after their first nuclear submarines, of the November class, entered service in 1958. Beginning in 1968, the Chinese built a few nuclear submarines while continuing to build large numbers of nonnuclear submarines.

Nuclear power plants. *Reactors.* A nuclear reactor provides the heat that powers a steam turbine, which in turn drives a propeller. There are three main types of marine nuclear reactor: pressurized-water, natural-circulation, and liquid-metal.

Generally, uranium in a reactor produces heat by nuclear fission. In the reactor, the uranium is surrounded by a moderator, which is required to slow the reaction neutrons so that they will interact more efficiently with the uranium. In most reactors the moderator is water, which is also used to carry away the heat of reaction. This heated water is called the primary loop water. Pressurized to prevent it from boiling, it runs through a heat exchanger, in which the heat is passed to another, secondary, water circuit. The heat exchanger is essentially a boiler, and the secondary circuit, or loop, provides the steam that actually turns the turbine. So long as a sufficient seal is maintained, the water of the primary loop cannot contaminate the rest of the power plant.

Pressurized and natural-circulation reactors

In most cases the water in the primary loop is circulated by pump. Reactors can also be arranged so that differences in temperature—for example, between that portion of the reactor containing the reacting fuel and the rest of the reactor—force the water to circulate naturally. Typically, in these natural-circulation reactors cooled water from the heat exchanger is fed into the bottom of the reactor, and it rises through the fuel elements as they heat it.

The liquid-metal-cooled reactor operates on the principle that molten metal can carry much more heat than water, so that a more compact turbine can be used. Against that advantage, molten metal can be made highly radioactive, so that leaks, which are dangerous enough in a pressurized-water plant, become much more so. Second, pumps in these reactors must be much more powerful, and the simplicity of using the same substance as moderator and heat sink is lost. Finally, there is always the possibility that enough heat will be lost for the plant to seize up, the metal solidifying in the pipes, with catastrophic results.

Adoption by navies. Under the direction of Captain (later Admiral) Hyman Rickover, the U.S. Navy developed both pressurized-water and liquid-metal prototypes. It completed its first two nuclear submarines, the *Nautilus* and *Seawolf,* to test the two types, but problems (including leakage) in the *Seawolf* reactor led to the abandonment of the liquid-metal scheme. Later the navy also developed natural-circulation reactors. U.S. attack submarines (except for USS *Narwhal,* the natural-circulation prototype) were built with pressurized-water reactors, but the Ohio-class strategic submarines of the 1980s were powered by natural-circulation reactors. The latter were inherently quieter than pressurized-water units because they required no pumps, at least at low and moderate power.

Soon after the *Nautilus* was completed, the Royal Navy adopted American-type pressurized-water reactors, but by the early 1980s it was developing natural-circulation reactors of its own design.

The first generation of French nuclear power plants, built for strategic submarines, were pressurized-water types. French attack submarines, on the other hand, were powered by natural-circulation units, at least at low and moderate speeds.

The Soviet Union revealed little about its nuclear submarine program, but most of its plants were apparently of the pressurized-water type. However, its most compact and powerful plant, in the very fast Alfa-class attack submarines of the 1970s and '80s, was thought to use liquid metal.

The nuclear navies. The advent of the new nuclear submarines had two great consequences. One was the rise of an altogether new kind of submarine, the strategic submarine. The other was a revolution in antisubmarine warfare, with attack submarines becoming the primary antisubmarine weapons. Attack submarines were armed with torpedoes and, in some cases, with antiship missiles. Strategic submarines carried similar weapons, but their primary weapons were submarine-launched ballistic missiles (SLBMs), such as the U.S. Polaris, Poseidon, and Trident and the Soviet SS-N-6 Sawfly, SS-N-18 Stingray, and SS-N-20 Sturgeon.

Strategic submarines. Strategic submarines were valuable because they were so difficult to find and kill, and they became even more important as long-range SLBMs became more accurate. Accurate missiles could destroy missiles in fixed land sites; were all strategic missiles so based, the side firing first could hope to disarm its enemy. However, with many missiles now based at sea, such a first strike became virtually impossible—barring some breakthrough in submarine detection. To the extent that preemptive attack was impractical, therefore, a force of strategic submarines became an effective deterrent against enemy attack. For this reason, the United States, the Soviet Union, Great Britain, France, and China all built submarines armed with SLBMs.

Strategic submarines actually predated the nuclear-propulsion era, in that during the 1950s both the U.S. and Soviet navies developed missile-carrying diesel-electric submarines. The U.S. submarines were armed with Regulus cruise missiles, and the Soviet ships carried SS-N-3 Shaddock cruise missiles and SS-N-4 Sark short-range SLBMs. However, these missiles had to be launched from the surface, and the submarines themselves could not remain submerged indefinitely. Strategic submarines did not become truly effective until nuclear power plants and dive-launched missiles enabled them to operate continuously without exposing themselves on the surface in any way.

The first modern strategic submarines were of the U.S. George Washington class, which became operational in 1959. These 5,900-ton, 382-foot vessels carried 16 Polaris missiles, which had a range of 1,200 nautical miles. In 1967 the first of the Soviet Union's 8,000-ton Yankee-class submarines were delivered, which carried 16 SS-N-6 missiles of 1,300-nautical-mile range. These were followed a decade later by Delta-class vessels fitted with 16 SS-N-18 missiles. Each SS-N-18 had a range of 3,500 nautical miles. In 1982 the Soviet Union began to deploy its Typhoon class, of 18,500 tons displacement at the surface and about 560 feet in length. These submarines carried 20 SS-N-20 SLBMs, each of which could carry its warheads a distance of 4,500 nautical miles.

The growing size and missile range of strategic submarines

Beginning in 1970, the United States fitted its Lafayette-class submarines with 16 Poseidon SLBMs, which could launch its warheads a distance of 2,500 nautical miles. To carry 24 Trident missiles, improved versions of which could travel about 6,500 nautical miles, the U.S. Navy commissioned the first Ohio-class submarine in 1981 (see Figure 35). These vessels displaced 16,600 tons at the surface and were about as long as the Soviet Typhoons.

Britain's first strategic submarines, of the Resolution class, entered service in 1967 with 16 Polaris missiles. The

Figure 35: *USS Ohio, strategic nuclear submarine of the U.S. Navy.* Commissioned in 1981, it carries 24 Trident ballistic missiles in a double row of vertical launch tubes (shown with hatches open). The average patrol time at sea of Ohio-class submarines is 70 days, and their nuclear reactor cores need replacement only once every nine years.

first Vanguard-class vessel was laid down in 1986 to carry 16 Trident missiles.

To supplement the Redoutable class of the 1970s, France built *L'Inflexible*. This 8,000-ton submarine, which entered service in 1985, carried 16 M-4 SLBMs, each with a range of 2,800 nautical miles. In 1988 the first of the Triomphant class was laid down; as replacements of the Redoutable class, these were designed to carry SLBMs of 6,000-nautical-mile range.

In 1981 China launched the fist Xia-class strategic submarine. It was armed with 12 CSS-N-3 missiles with a range of 1,500 nautical miles.

Attack submarines. After the rise of nuclear-powered strategic submarines, it seemed that only other nuclear submarines could maneuver in three dimensions and remain in contact long enough to destroy them. Surface ships were clearly handicapped because their sonars could not operate as freely as those of a submarine. That situation changed somewhat when surface warships began to tow passive sonar arrays at submarine-like depths and when ship- or helicopter-launched homing torpedoes acquired a fair chance of holding and killing their targets. Both submarines and surface ships, therefore, became effective antisubmarine weapons, but only submarines could operate near an enemy's bases, where hostile submarines would be easier to find, and only they could lie in ambush with little chance of being detected.

Most modern nuclear attack submarines adopted a dual function: to attack enemy surface ships and to destroy enemy submarines. For example, the U.S. Sturgeon submarines of the 1960s and '70s and their successors, the Los Angeles class, carried torpedoes and rocket-launched nuclear depth bombs for antisubmarine warfare as well as underwater-launched Harpoon missiles for attacking surface ships from as far away as 70 nautical miles. From 1984 both classes were fitted with Tomahawk cruise missiles, which could be programmed to strike ships 250 nautical miles away or, in a strategic variant, to hit land targets with a nuclear warhead at ranges up to 1,300 nautical miles.

Soviet cruise-missile submarinesThe Soviets tended to divide their attack submarines between antisubmarine and cruise-missile duties. Beginning in 1971, the SS-N-7 Star Bright cruise missile, which could be launched underwater and could strike ships 35 nautical miles away, was deployed in Charlie-class submarines. The SS-N-7 began a series of dive-launched antiship cruise missiles of increasing range, culminating in the SS-N-19 Shipwreck, a supersonic missile that could carry a nuclear warhead 340 nautical miles. Twenty-four of these weapons were carried aboard the 13,000-ton, 500-foot Oscar submarines, which entered service in 1980.

The most prominent submarine-hunting submarines of the Soviet Union were of the three Victor classes. The Victor I vessels, which entered service beginning in 1968, introduced the "tear-drop" hull configuration to the underwater Soviet Navy. These and the 6,000-ton Victor II and III classes of the following decades were fitted with rocket-launched torpedoes or nuclear depth bombs, giving them a battle range extending to 50 nautical miles.

Adding a further role to Soviet attack submarines after 1987 was the SS-N-21 Sampson cruise missile, a weapon with a nuclear capability and range similar to those of the U.S. Tomahawk.

The British Valiant, Swiftsure, and Trafalgar classes of the 1960s, '70s, and '80s displaced between 4,000 and 4,500 tons at the surface and were about 285 feet long. They were armed with torpedoes and dive-launched Harpoon missiles. In France, the first Rubis-class submarine was laid down in 1976 with torpedo and sonar systems inherited from the diesel-electric Agosta class. Beginning in 1984, new and existing vessels of this class were given improved sonar and silencing and were fitted with dive-launched Exocet antiship missiles. They displaced about 2,400 tons at the surface and were about 235 feet long.

Design principles. After 1955 the three main trends in nuclear attack submarine design in the United States, Britain, and the Soviet Union were increased speed, increased diving depth, and silencing.

Speed. Increased speed required increased power. Since the resistance a submarine encounters is a function of its surface area, the ideal was to achieve greater power without increasing the volume or weight of the power plant and, therefore, the size of the submarine. A more powerful (and therefore noisier) engine could be silenced, but only by increasing the size of the submarine, which in turn would lower its speed. These complex trade-offs were illustrated by the Sturgeon and Los Angeles submarines. Reactor power approximately doubled between these two generations, but overall size increased enormously, from about 3,600 to 6,000 tons surfaced. The Soviets, meanwhile, achieved very high speed (about 40 knots, compared to slightly over 30 knots for fast Western submarines) in their Alfa class, but probably at the cost of a great deal of noise at high speed.

Speed was prized for several quite different reasons. At first, the U.S. and Soviet navies developed fast submarines primarily as antiship weapons. In the 1950s the Guppy-style hull design of USS *Nautilus* gave it a submerged speed of over 20 knots, which was fast enough to evade surface ships but not to counterattack them. To make up this deficit, U.S. submarines then under design were altered by adapting nuclear power to the tapered "tear-drop" hull of the experimental submarine *Albacore.* The resulting Skipjack class, which entered service in 1959, came up with a top speed in excess of 30 knots.The "tear drop" hull

In a spectacular demonstration of the Soviets' fast attack capabilities, a Soviet nuclear submarine intercepted the nuclear aircraft carrier USS *Enterprise* in February 1968. The submarine was not quite as fast as the *Enterprise*, but it was fast enough to keep the carrier within weapon range while the carrier accelerated to top speed.

With the commencement of the Soviet fast nuclear program, the U.S. Navy shifted its emphasis to dual-purpose vessels capable of attacking submarines as well as surface ships. High speed, as achieved in the 1970s and '80s by the Los Angeles class, was then required to keep up with the fast surface targets that the Soviet submarines were expected to attack.

High sustained speed also made it possible for submarines to deploy more efficiently to distant patrol stations. Although nuclear submarines' fuel supplies were effectively unlimited, they were limited in their capacity for stores and could not expect to remain at sea for more than about 60 to 90 days. The more rapidly they could reach their patrol area, therefore, the more productive time they could spend there.

As in the case of nonnuclear submarines, higher speed was also valued for evasion after an attack. However, when that higher speed was bought at the cost of louder operation, submarines became easier to detect. Also, from the mid-1950s the main antisubmarine weapons were homing torpedoes, which became significantly faster than the submarines they sought, and nuclear depth bombs, which might be dropped effectively anywhere in the vicinity of a submarine. In all of these cases, sheer speed was no longer a guarantee of evasion, although it did make attack more difficult.

Depth. Deeper diving was valued for several reasons. As in the past, it could be combined with higher speed for better evasion. In addition, a deep-diving submarine could make better use of its own sonar, partly because it could operate in several quite different layers of the sea. This advantage was reflected in a change in U.S. submarine sonars that began about 1960. Previous submarine units had been cylindrical, producing broad, fan-shaped beams that could determine target range and bearing but not target depth. The new sonars were spherical, producing narrow, pencil-shaped beams that could distinguish between targets at different depths. They could also make better use of sonar reflection off the sea bottom and surface to achieve greater range.

Finally, greater maximum operating depth became particularly important at high speed, when there was always a possibility that a submarine would accidentally tip down and descend below a safe operating depth before the downward motion could be corrected. It is no surprise, then, that the greatest reported diving depth (about 2,800 feet) was associated with the highest reported maximum speedDiving depth of attack submarines

(about 43 knots), in the Soviet Alfa class. (Diving depth of most other modern attack submarines was reportedly between 1,000 and 1,500 feet.)

Greater depth required a stronger (and heavier) hull, and increased power required a stronger power plant. Attempts to combine the two required a larger hull (to provide enough buoyancy); that in turn added underwater resistance, which cut the speed advantage gained from the more powerful engine. This tension between different requirements explains the characteristics of many modern submarines. For example, the Los Angeles class was said to have sacrificed some diving depth in order to achieve higher speed. In the Alfa class, weight was saved by adopting an expensive titanium-alloy hull and a very compact power plant.

Silencing. Until the late 1950s, submarines were usually detected by active sonar; that is, by sound waves bounced off their hulls. Because these sound waves could also be detected by the hunted submarine, they gave it warning that it was in danger of attack. Also, because water can support only so much sonar energy, active sonar was limited in range. Beginning in the early 1950s, then, the U.S. and British navies began to investigate passive sonar, in which sensors detected noises emanating from the submarine itself. Early nuclear submarines were quite susceptible to such detection because their machinery was very noisy. In particular, the pumps required to circulate the coolant, which could not be turned off without melting the reactor core, could be heard at a considerable distance.

Beginning at that time, silencing became a major thrust in submarine design. The pumps of pressurized-water reactors were redesigned to be quieter, and in many submarines the machinery was carried clear of the hull on sound-absorbing mounts. All of this added to the size and weight of the machinery and to the expense of construction; it also added to the attraction of natural-circulation plants.

As a further step in silencing, hulls were coated with sound-absorbing material. Even relatively simple coatings could drastically reduce the effectiveness of homing torpedoes.   (N.F.)

Military aircraft

Aircraft have been a fundamental part of military power since the mid-20th century. Generally speaking, all military aircraft fall into one of the following categories: fighters, which secure control of essential airspaces by driving off or destroying enemy aircraft; bombers, which are larger, heavier, and less maneuverable craft designed to attack surface targets with bombs or missiles; ground-support, or attack, aircraft, which operate at lower altitudes than bombers and air-superiority fighters and attack tanks, troop formations, and other ground targets; transport and cargo planes, big-bodied craft with large amounts of interior space for carrying weapons, equipment, supplies, and troops over moderate or long distances; and helicopters, which are rotary-winged aircraft used for ground support, to transport assault troops, and for short-distance transport and surveillance.

EARLY HISTORY

When the first practical aircraft were produced, in the form of hot-air and hydrogen balloons in 1783, they were adopted quickly for military duties. In 1793 the French Convention authorized formation of a military tethered-balloon organization, and a company of "Aérostiers" was formed on April 2, 1794. Two months later the first military reconnaissance from such a balloon was made before the city of Maubeuge. Until the Aérostiers were disbanded in 1799, their reports contributed to the success of French armies in many battles and sieges. Similar reconnaissance balloons were used later by other armies, notably by both armies during the American Civil War and by the British in Africa from 1884 to 1901.

The beginning of military aviation   True military aviation began with the perfection of the navigable airship in the late 19th century and the airplane in the first decade of the 20th century. The brothers Wilbur and Orville Wright, who made the first powered,

sustained, and controlled flights in an airplane on Dec. 17, 1903, believed such an aircraft would be useful mainly for military reconnaissance. When they received the first contract for a military airplane from the U.S. government in February 1908, it called for an aircraft capable of carrying two persons at a speed of at least 40 miles (64 kilometres) per hour for a distance of 125 miles. The aircraft they delivered in June 1909 was listed as "Airplane No. 1, Heavier-than-air Division, United States aerial fleet."

The most formidable aircraft of the years before World War I were airships rather than airplanes. Airships were large, self-propelled craft usually consisting of a rigid, fabric-covered metal frame within which were gas bags containing a lighter-than-air gas such as hydrogen. The most ambitious examples of this type of craft were the huge airships designed and built in Germany by Ferdinand, Count von Zeppelin. A typical zeppelin could carry five 110-pound (50-kilogram) high-explosive bombs and 20 6.5-pound incendiary bombs at a time when most military airplanes were without any form of weapons, being intended only for reconnaissance.

Experiments with arming airplanes were made spasmodically after 1910, when August Euler took out a German patent on a machine-gun installation. Bombing techniques evolved simultaneously. Dummy bombs were dropped on a target in the form of a ship by the American designer Glenn Curtiss on June 30, 1910. This test was followed by the dropping of a real bomb and the devising of the first bombsight. In England the Royal Flying Corps (RFC) fitted some of its aircraft with bomb carriers, which consisted of a kind of pipe rack beside the observer's cockpit in which small bombs were retained by a pin. The pin was pulled out over the target by tugging on a string. It was primitive but it worked. The Naval Wing of the RFC subsequently attempted to drop torpedoes from Short and Sopwith seaplanes, with some success, and efforts were soon under way to develop means to launch and recover such craft on shipboard. In 1910–11 a Curtiss biplane had been flown from and onto wooden platforms erected over the decks of anchored U.S. Navy cruisers, and in May 1912 a pilot of the Naval Wing, RFC, flew a Short S.27 biplane from HMS *Hibernia* while the ship was steaming at 10.5 knots. The following year the old cruiser *Hermes* was fitted with a short deck from which seaplanes took off on wheeled trolleys that were fitted under their floats and dropped away as the machines became airborne.

Thus, by 1914, reconnaissance, bomber, and carrier-based aircraft all were evolving, and some had been used in combat. The first use of an airplane in war was on Oct. 23, 1911, during the Italo-Turkish War, when an Italian pilot made a one-hour reconnaissance flight over enemy positions near Tripoli, Libya, in a Blériot XI monoplane. The first bombing raid came nine days later, when a pilot dropped four grenades on Turkish positions. The first reconnaissance photographs of enemy positions were taken on Feb. 24–25, 1912, in the same conflict. | The first bombing raid

WORLD WAR I

Airships.   At the start of the war the German armed forces had 10 zeppelins and three smaller airships, but this impressive offensive capability was largely offset by the highly explosive nature of the hydrogen gas that gave the zeppelins their lifting power. After losing three zeppelins in daylight raids over heavily defended areas in the first month of the war, the army abandoned airship operations, but the navy, with its battle fleet blockaded in port by the Royal Navy, mounted a night bombing offensive—the first aerial strategic bombardment campaign in history.

The finest of the zeppelins was the LZ-70; this craft was 740 feet (220 metres) long, was able to fly above 16,000 feet, and had a range of 7,500 miles. The LZ-70 was shot down late in the war, however, and large rigid (metal-framed) airships were never again employed as combat aircraft. Smaller, nonrigid airships were used throughout World War I by the British for antisubmarine patrol, convoy escort, and coastal reconnaissance, achieving a remarkable record of protecting coastal convoys from German submarines. They were revived by the U.S. Navy during World War II for the same use.

Unpowered, captive balloons also were used extensively for observation and artillery spotting in World War I, but by World War II they had become so vulnerable that they were used only as unmanned antiaircraft barrage balloons. Anchored to the ground or ships by cables, they compelled attacking enemy aircraft to fly high to avoid the cables; they also brought down many German pilotless V-1 "buzz bombs" over England in 1944–45.

Reconnaissance aircraft. At the outbreak of World War I, heavier-than-air craft were used only for visual reconnaissance, since their feeble engines could carry little more than a pilot and, in some cases, an observer aloft. They soon proved their worth in this mission, however, and RFC aviators provided reconnaissance that enabled the British and French armies to counterattack in the decisive Battle of the Marne on Sept. 6–12, 1914, turning back the invading Germans just short of Paris.

More powerful engines and better aircraft designs soon made possible specialized reconnaissance aircraft that could fly at high altitudes to avoid interception. The Germans, for example, had Rumpler two-seaters in service by 1917 that could operate as high as 24,000 feet. Radios were carried aloft to permit aerial observers to spot and adjust artillery fire, at first with transmitters only and then, as radios became lighter, with receivers for two-way communication.

Fighters. The importance of aerial reconnaissance and artillery spotting (particularly the latter) made it clear that the belligerent able to deny the enemy use of airspaces above the battlefield would enjoy enormous advantages. This realization led to the emergence of fighters as a distinct category of aircraft. In the early days of the war, pilots and observers blazed away at enemy aircraft with pistols, rifles, and even shotguns, but to little effect. Machine guns were the obvious solution. In 1913 the Vickers company in Britain had exhibited a two-seat biplane of pusher configuration (*i.e.,* with the propeller behind the engine) that was armed with a machine gun fired by an observer who sat ahead of the pilot in a tublike crew compartment. A development of this machine, the Vickers F.B.5 Gunbus, entered service in early 1915 as the first production aircraft designed from the outset with air-to-air armament. The French armed similarly configured Voisin pushers with machine guns (one had shot down a German aircraft as early as Oct. 5, 1914), but, burdened with the extra weight of observer and gun, such aircraft were slow and unmaneuverable, and their successes were mostly the result of accidental encounters. Light, single-seat aircraft of tractor configuration (*i.e.,* with the propeller at the nose) had much better performance, but efforts to arm them with machine guns firing at an angle to avoid hitting the propeller produced little success.

The solution to the problem emerged in the spring of 1915 in the form of an interrupter gear, or gun-synchronizing device, designed by the French engineer Raymond Saulnier. This regulated a machine gun's fire so as to enable the bullets to pass between the blades of the spinning propeller. The interrupter itself was not new: a German patent had been taken out on such a device by the Swiss engineer Franz Schneider before the war. The real breakthrough was made by Roland Garros, a famous sporting pilot before the war and a friend of Saulnier, who perceived that a machine gun fitted with such a device and mounted rigidly atop the fuselage could be aimed accurately simply by pointing the airplane in the desired direction. Though the French machine gun had a tendency to "hang fire," so that steel deflector plates had to be fitted onto the rear of the propeller blades to prevent their being shot off, Saulnier quickly perfected his device and fitted it to Garros's Morane L monoplane. With this machine, Garros shot down three German aircraft on April 1, 13, and 18. Then, on April 19, Garros himself force-landed with a ruptured fuel line and was taken prisoner. His efforts to burn his aircraft failed, and the secrets of Saulnier's interrupter gear were laid bare. The Germans reacted quickly, putting the designer Anthony Fokker to work on a similar device. With Saulnier's gear as his inspiration (and perhaps drawing on earlier German work), Fokker swiftly came up with an efficient interrupter gear, which

The first true fighter aircraft

Figure 36: Fokker Eindecker, German fighter plane of World War I.

he fitted onto a monoplane of his own design—ironically, a copy of a French Morane. The result was the Fokker Eindecker ("monoplane"; see Figure 36), which entered service in July 1915 and reigned supreme in the air over the Western Front until the following October—a period known among Allied aviators as the "Fokker Scourge."

The Fokker Eindecker

The Eindecker's mastery was ended by new versions of the French Nieuport with a machine gun mounted above the top wing, allowing it to fire clear of the propeller arc, and by British D.H.2 and F.E.2b pushers with nose-mounted guns. Though a superb flying machine, the Nieuport was limited by its light armament, while the two British machines had brought the aerodynamically inefficient pusher configuration to its limit and were soon outclassed. Thereafter, the pace of fighter development began to be set by improvements in engine design—a phenomenon that was to persist well into the jet age.

Most Allied fighters at that time were powered by rotary radial engines (*i.e.,* with the cylinders, arranged radially about the crankcase like the spokes of a wheel, rotating around a stationary crankshaft). These engines were relatively powerful in relation to their weight, but their large frontal areas produced a great deal of drag, and the gyroscopic forces induced by their whirling mass posed serious aircraft control problems. In mid-1916 Germany took the lead in fighter design on the basis of its superb Daimler and Benz water-cooled, in-line engines, such as those which powered the streamlined Albatros D.I, D.II, and D.III series of fighters. These were faster than their Allied opponents and, most important, could carry two machine guns without sacrificing performance. The Albatros D.I pioneered a fighter configuration that was to prevail into the 1930s: a compact, single-seat, externally braced tractor biplane armed with two synchronized machine guns mounted ahead of the pilot on the upper fuselage decking and aimed with a simple ring-and-bead sight. Albatros fighters gave British airmen a terrible drubbing above the Arras battlefield during the "Bloody April" of 1917, but a new generation of French and British fighters with more powerful engines soon tilted the balance toward the Allies. Prominent among these were the French Spad fighters and the British S.E.5, both powered by the Spanish-designed and French-built Hispano-Suiza water-cooled V-8, as well as the British Sopwith Camel and new versions of the French Nieuport, powered by improved rotary radial engines.

Though Germany fell decisively behind France and Britain in aircraft production in 1917, and thus lost the war in the air, perhaps the definitive single-seat fighter of World War I was the Fokker D.VII of 1918. Typically powered by a 160-horsepower Mercedes engine, the D.VII was a fabric-covered biplane that differed from others in having a sturdy fuselage structure of welded steel tubing. Armed with two machine guns, it had a top speed of 117 miles per hour. Even more powerful engines made two-seat fighters possible; the best of these was the British Bristol F.2b, powered by the 220-horsepower, water-cooled Rolls-Royce Falcon, a V-12 engine that gave the Bristol a top speed of almost 120 miles per hour. The F.2b was armed with a synchronized machine gun for the pilot and two flexible machine guns for the observer.

The Fokker D.VII

Ground attack. The Allies fielded specialized aircraft for ground attack only at the very end of the war. Notable among these was the Sopwith Salamander, a development

of the Sopwith Camel with an armoured cockpit and two machine guns firing downward through the floor at a fixed angle to rake enemy trenches while flying low over them. The Germans produced a number of specialized two-seat aircraft for this purpose—notably the Halberstadt CL.III of 1917, which was armed with a forward-firing synchronized machine gun as well as a flexible gun and racks of grenades for the observer. At the Battle of Cambrai in November and December 1917, the Germans sent large formations of such aircraft over the British trenches and into the rear areas with devastating effect. By the end of the war, they were using numbers of armoured, all-metal Junkers J.1 ground-attack aircraft, one of the most advanced machines to see combat during the war.

Bombers. Since they had to carry heavy disposable loads over long distances in order to be effective, specialized bombers were slower to develop. The first bombing raids to achieve significant success (and the first to cross national boundaries) were mounted against the Zeppelin works at Friedrichshafen from Belgian bases by airmen of the Royal Naval Air Service (RNAS) on Oct. 8 and Nov. 21, 1914. However, their spectacular success owed more to the highly flammable nature of the zeppelins themselves than to the destructive power of the 20-pound bombs used. These raids prompted the Admiralty to commission the development of the first specialized heavy night bomber, the Handley Page H.P. O/100, which flew for the first time in December 1915. Meanwhile, other air forces began building and putting into service strategic day bombers. Among the first were French Voisins. The type L was used in early 1915 to carry about 130 pounds of small bombs that simply lay in the bottom of the cockpit until the time came for the observer to drop them overboard. Later models had more powerful engines and were equipped alternatively as attack aircraft, carrying up to 660 pounds of bombs or having a 37-millimetre gun mounted in the nose. None flew faster than 84 miles per hour, so the Voisins operated mainly under cover of darkness in the last year of the war.

Italy, too, was quick to appreciate the value of bombing attacks on enemy targets. Its big three-engined, twin-tail-boom Capronis were among the finest bombers of World War I (see Figure 37). Even larger were the Russian Ilya Muromets bombers of the tsar's Squadron of Flying Ships. Designed by Igor Sikorsky, now remembered mainly as a helicopter pioneer, these biplanes spanned about 100 feet and were descended from his "Russky Vityaz" of May 1913, the world's first successful four-engined airplane. About 80 were built, and they made 400 raids on German targets with the loss of only one plane. The best-known German strategic bombers of World War I were twin-engined Gotha "pusher" biplanes, which made several daylight raids on London in formation in the summer of 1917 before reverting to night operations. The German air force also operated a family of giant four-engined metal bombers known as Riesenflugzeug, or R-planes. Typical of these was the Staaken R.VI number R.25, which was

The Gotha bombers

powered by four 260-horsepower Mercedes engines. This had a takeoff weight of 25,269 pounds, which included a crew of seven and a bomb load of up to 4,000 pounds.

Naval aviation. Equally significant progress was made in naval flying in World War I. Three distinct categories of combat aircraft emerged: long-range over-water reconnaissance and antisubmarine aircraft operating from shore bases, shorter-range floatplane reconnaissance and fighter aircraft, and ship-borne aircraft. Long-range flying boats (so called because their fuselages were shaped like the hull of a boat) were used extensively by the British. These pioneered the technique of searching for submarines with methodical, mathematically developed search patterns. The German navy made extensive use of reconnaissance and fighter floatplanes from Belgian coastal bases to counter Allied air patrols and coastal naval operations. Some of these, notably Hansa-Brandenburg machines designed by Ernst Heinkel, rivaled their land-based equivalents in performance.

The most efficient of the long-range coastal-based airplanes were large, twin-engined flying boats designed by Glenn Curtiss and others. Despite their bulk, these aircraft were sufficiently fast and maneuverable to engage enemy zeppelins and aircraft in combat. Curtiss' flying boats were the only aircraft of U.S. design to see frontline combat service in World War I.

Carrier-based air power also advanced rapidly. In early 1916 the first landplanes (British Sopwith Pups) were flown off the 200-foot decks of primitive carriers that had been converted from merchant ships, and on Aug. 2, 1917, a pilot landed a Pup on the takeoff deck of HMS *Furious* while the ship was under way. The concept of the true aircraft carrier had been born.

Britain went on to develop more formidable naval aircraft, and in October 1918 a squadron of Sopwith Cuckoos, each able to carry an 18-inch torpedo, was embarked on HMS *Argus*. The war ended before the squadron could go into action; but the RNAS had already used torpedoes dropped from Short seaplanes to sink enemy ships in the Mediterranean, and the Cuckoo, with its modest top speed of 103 miles per hour and endurance of four hours, heralded the eventual demise of the battleship in the face of air-power dominance at sea.

Air transport and training. Military air transport showed little development in 1914–18. Aircraft were used on occasion to drop supplies to cut-off or besieged forces, but the methods were primitive in the extreme: bags of food, medical supplies, or munitions were dropped from bomb racks or simply heaved over the side.

Conversely, training made enormous strides during the war. At the RFC School of Special Flying at Gosport, Eng., Major Robert Smith-Barry introduced a curriculum based on a balanced combination of academic classroom training and dual flight instruction. Philosophically, Smith-Barry's system was based not on avoiding potentially dangerous maneuvers (as had been the case theretofore) but on exposing the student to them in a controlled manner so that he could learn to recover from them, thereby gaining confidence and skill. Technologically, it was based on the Avro 504J, a specialized training aircraft with dual controls, good handling characteristics, adequate power, and in-flight communication between instructor and student by means of an acoustic system of soft rubber tubing—the so-called Gosport tube. For the first time, military pilots flew into action as masters of their airplanes. The Gosport system of training was eventually adopted at training schools throughout the world, remaining the dominant method of civil and military flight instruction into the jet age.

The Gosport system

INTERWAR DEVELOPMENTS

In the two decades between the end of World War I and the start of World War II, military aviation underwent a complete transformation. The typical combat aircraft of 1918 was a fabric-covered, externally braced biplane with fixed landing gear and open cockpits. Few aero engines developed as much as 250 horsepower, and top speeds of 120 miles per hour were exceptional. By 1939, the first-line combat aircraft of the major powers were all-

By courtesy of John W R Taylor

Figure 37: Italian Caproni bomber of World War I.

metal monoplanes with retractable landing gear. Powered by engines that developed 1,000 horsepower or more and that were supercharged to permit flight at altitudes above 30,000 feet, fighters were capable of exceeding 350 miles per hour, and some bombers flew faster than 250 miles per hour. Gyroscopically driven flight instruments and electrical cockpit lighting permitted flying at night and in adverse weather. Crews were seated in enclosed cockpits, were provided with oxygen for breathing at high altitudes, and could converse with other aircraft and ground stations by voice radio. Parachutes, worn by a few German fighter pilots in the last days of World War I, were standard equipment.

Most of these changes occurred after 1930. The end of World War I left the victorious Allies with huge inventories of military aircraft, and this combined with economic strictures and a lack of threat to retard the development of military aviation in the 1920s. Provisions of the Treaty of Versailles prohibiting developments in military aviation had the same effect in Germany. Nevertheless, advances in key technologies, notably high-performance aero engines, continued. The U.S. government, for instance, sponsored a systematic program of aerodynamic research under the aegis of the National Advisory Committee for Aeronautics (NACA), which was to yield enormous dividends in aircraft performance through drag-reduction, engine-cooling, and airfoil technologies. Still, the most significant technical advance in the 1920s was the abandonment of wooden structures in favour of metal frames (still fabric-covered) to provide the strength needed to cope with increasingly powerful engines and to resist harsh climates around the world.

Civilian design improvements. When more drastic changes came, they emerged not from military requirements but from civilian air racing, particularly the international seaplane contests for the coveted Schneider Trophy. Until the appearance of variable-pitch propellers in the 1930s, the speed of landplanes was limited by the lengths of existing runways, since the flat pitch of high-speed propellers produced poor takeoff acceleration. Seaplanes, with an unlimited takeoff run, were not so constrained, and the Schneider races, contested by national teams with government backing, were particularly influential in pushing speeds upward. During the 1920s the Curtiss company built a remarkable series of high-speed racing biplanes for the U.S. Army Air Corps and Navy. These were powered by the innovative D-12, a 12-cylinder, liquid-cooled engine, also of Curtiss design, that set international standards for speed and streamlining. One of the Curtiss planes, an R3C-2 piloted by Lieutenant James Doolittle, won the 1925 Schneider race with a speed of 232.5 miles per hour— in sharp contrast to the winning speed of 145.62 miles per

The role of the Schneider races

Figure 38: Supermarine Spitfire, Britain's premier fighter plane from 1938 through World War II.

hour in 1922, before the Curtiss machines took part in the event. The influence of the Curtiss engine extended to Europe when British manufacturer C.R. Fairey, impressed with the streamlining made possible by the D-12, acquired license rights to build the engine and designed a two-seat light bomber around it. The Fairey Fox, which entered service in 1926, advanced the speed of Royal Air Force (RAF) bombers by 50 miles per hour and was faster than contemporary fighters. Nor were British engine manufacturers idle; when the U.S. Army and Navy standardized on air-cooled radial engines in the 1920s, Curtiss ceased developing liquid-cooled engines, but British engine designers, partly inspired by the D-12, embarked on a path that was to produce the superlative Rolls-Royce Merlin.

The year that Doolittle won the Schneider Trophy, an even more revolutionary design appeared—the S.4 seaplane designed by R.J. Mitchell of the British Supermarine Company. A wooden monoplane with unbraced wings, the S.4 set new standards for streamlining, but it crashed from wing flutter before it could demonstrate its potential. Nevertheless, it was the progenitor of a series of monoplanes that won the trophy three times, giving Britain permanent possession in 1931. The last of these, the S.6B, powered by a liquid-cooled Rolls-Royce racing engine with in-line cylinders, later raised the world speed record to more than 400 miles per hour. The S.6B's tapered fuselage and broad, thin, elliptical wings were clearly evident in Mitchell's later and most famous design, the Spitfire (see Figure 38).

In the United States the Thompson Trophy, awarded to the winner of unlimited-power closed-circuit competitions at the National Air Races, was won in 1929 for the first time by a monoplane, the Travel Air "R" designed by J. Walter Beech. Powered by the Wright Cyclone, a 400-horsepower radial engine with a streamlined NACA cowling that contributed 40 miles to its maximum speed of 235 miles per hour, the "R" handily defeated the far more powerful Curtiss biplanes flown by the army and navy. Embarrassed, the military withdrew from racing— and the army soon ordered its first monoplane fighter, the Boeing P-26. In 1935 the industrialist Howard Hughes set a world landplane speed record of 352 miles per hour in a racer designed to his own specifications and powered by a 1,000-horsepower, twin-row radial engine built by Pratt & Whitney. The Hughes H-1 was a low-wing monoplane built with unbraced wings and a "stressed-skin" metal covering that bore stress loads and thereby permitted a reduction in weight of the internal structure. These features, along with a flush-riveted, butt-joined aluminum fuselage, an enclosed cockpit, and power-driven, retractable landing gear folding flush into the wing, anticipated the configuration, appearance, and performance of the fighters of World War II.

Fighters. By the 1930s the advantages of monoplanes with unbraced wings and retractable landing gear were evident, and fighters of this description began to appear. The first of these to see operational service was the Soviet I-16, designed by Nikolay Polikarpov. The I-16 first flew in 1933 and enjoyed considerable success against German and Italian biplanes in the Spanish Civil War of 1936–39. Powered by a radial engine derived from the Wright Cyclone, it had manually retracted landing gear and an open cockpit; its armament of four 7.62-millimetre machine guns, two in the wings and two in the engine cowling, was heavy for the time.

As the I-16 entered combat in Spain, two important British fighters were under development: the Supermarine Spitfire, a cleanly elegant fighter of stressed-skin aluminum construction, and the Hawker Hurricane, a more traditional design with a structural frame of welded steel tubes and a fabric covering over the rear fuselage. Both were powered by a Rolls-Royce Merlin engine of some 1,200 horsepower, and both carried an unprecedented armament of no fewer than eight .303-inch Browning machine guns, mounted in the wings outboard of the propeller arc so that no interrupter gear was needed. Meanwhile, in Germany the nascent Luftwaffe (Air Force) was taking delivery of the first versions of the Bf 109, designed by Willy Messerschmitt for the Bayerische Flugzeugwerke ("Bavarian Aircraft Factory"). Like the Spitfire, the Bf 109 was a low-

The Supermarine Spitfire

wing monoplane of all-metal, stressed-skin construction. Early versions, fitted with fixed-pitch propellers, fought on a par with the I-16 in Spain, but later versions, powered by a Daimler-Benz engine that was equivalent to the Merlin and fitted with variable-pitch propellers for optimal performance at low and high altitudes, totally outclassed the Russian fighter.

Bombers. Bombers evolved in parallel with fighters, changing to high-strength metal construction in the late 1920s and to monoplane design, which brought higher speeds, in the early 1930s. In 1931 the Boeing Aircraft Company produced the B-9 bomber. Anticipating all-metal fighters, the B-9 was the first operational combat aircraft with all-metal cantilever monoplane design, semiretractable undercarriage, and variable-pitch propellers. Two 600-horsepower engines gave it a speed of 188 miles per hour, representing a 50-percent improvement over the biplane bombers then in service, without any reduction in bombload. Within months of its first flight, the B-9 was overshadowed completely by the Martin B-10 of 1932, which brought the biggest single advance in bomber design since the Handley Page night bomber of World War I. To the innovations of the B-9 it added enclosed cockpits and an internal bay for its 2,260-pound bombload. Maximum speed went up to 213 miles per hour, making the B-10 faster than the fighters of its day. Following this success, Boeing built in 1935 a four-engined craft known as the Model 299, which became the prototype of the B-17 Flying Fortress. This famous plane was based on the concept that a bomber could penetrate to any target in daylight as long as it had sufficient defensive armament to battle past fighter opposition. Gun turrets for defensive machine guns had already been pioneered by Machines Motrices in France, and a license-built version of their turret had appeared on the British Boulton Paul Overstrand bomber in 1934. Meanwhile, the U.S. Army Air Corps claimed that its highly secret Norden bombsight provided such accuracy that "a bomb could be placed in a pickle barrel from 20,000 feet."

An important type of bomber to emerge in the interwar period was the dive-bomber, designed to release its bombs at a low point of a steep dive. Accuracy was maintained by the use of airbrakes, which were flaps that could be extended outward to slow the dive by increasing the aircraft's drag. The dive-bomber as a distinct type of aircraft was a product of tests undertaken during the 1920s by the U.S. Navy. These demonstrated the advantages of bombing the lightly armoured upper decks of warships and resulted in the appearance of the first real dive-bomber, the Curtiss F8C Helldiver, in 1929. Impressed by a Helldiver demonstration, the Luftwaffe, whose doctrine stressed the direct support of ground forces, requested a more advanced aircraft with similar capabilities. The result was the Ju 87 "Stuka" (for *Sturzkampfflieger,* or "dive-bomber"; see Figure 39), which gained a fearsome reputation for destructiveness during the Spanish Civil War.

Carrier aircraft. By the 1930s, ship-based aircraft were fitted under the tail with arrester hooks that engaged cables strung across the landing deck in order to bring them to a halt after landing. Folding wings then enabled them to be taken by elevator to below-deck hangars. Japanese and U.S. aircraft carriers had mixed complements of single-seat fighters, dive-bombers, and torpedo planes; the Royal Navy pursued a less successful course, developing two-seat reconnaissance fighters, such as the Fairey Fulmar, which were outperformed by their land-based equivalents.

WORLD WAR II

Fighters. *Day fighters.* Air superiority was crucial to the outcome of most of the decisive campaigns of World War II, and here the performance of single-seat fighters was generally the critical factor. First-class fighters required extremely powerful aero engines suitable for compact, low-drag installation, and in this respect Britain, Germany, and the United States were in a class by themselves. The only significant exception was the Japanese Mitsubishi A6M carrier fighter, known as the Zero. Designed by Horikoshi Jiro, the Zero was so remarkably strong and light that it achieved first-class performance with a second-

Figure 39: German Junkers Ju 87 Stuka dive-bomber.
UPI

class engine—though at the cost of being vulnerable to battle damage.

The outstanding fighters of the early war years (1939–41) were the Spitfire, Bf 109 (known to the wartime Allies as the Me 109), Zero, Hurricane, and Grumman F4F Wildcat (this last a U.S. Navy fighter powered by a turbosupercharged, twin-row radial engine by Pratt & Whitney). The Lockheed P-38 Lightning, a novel twin-boom interceptor designed before the war by Clarence ("Kelly") Johnson, had exceptional performance, but until 1943 it was available only in small numbers. The main U.S. Army Air Force fighters of the early war, the Curtiss P-40 Warhawk and the Bell P-39 Airacobra, were badly outclassed by the Bf 109 and Zero as a result of production decisions that deprived their high-performance Allison engines of scarce turbosuperchargers, assigning them instead to bombers. The best Soviet fighters were similarly outclassed: the MiG-3, designed by a bureau headed by Artem Mikoyan and Mikhail Gurevich, was fast, but it had marginal handling characteristics at low altitudes, and the performance of Semyon Lavochkin's LaGG-3 was ruined by a disastrously heavy airframe.

The Spitfire and Hurricane were determined opponents of the Bf 109 during the Battle of Britain, the first battle fought entirely in the air. The German fighter was armed with two machine guns in the cowling and two wing-mounted cannon firing 20-millimetre exploding shells. Aerial cannon, perfected by the Germans during the war, was intended to ensure the greatest possible destruction against metal-skinned aircraft in the short periods during which a target could be kept in the gunsights at rapidly increasing speeds. It was superior in fighter-to-fighter combat, while the massed batteries of .303-inch machine guns in the British fighters were highly effective in destroying bombers. Aiming was accomplished by gyroscopic lead-computing gunsights that projected the aim point onto a transparent screen in front of the pilot.

More powerful and heavily armed versions of the Spitfire and Bf 109 were tactically viable through the end of the war, but they were hampered by a short radius of action (the farthest distance to which they could fly, engage in combat, and return to base). In 1942–43, fighters began to enter service fitted with newer and more powerful engines and designed on the basis of the most recent aerodynamic data. Notable among these were the German Focke-Wulf Fw 190, designed by Kurt Tank, and the U.S. Republic P-47 Thunderbolt, Grumman F6F Hellcat, and North American P-51 Mustang. All were heavily armed, the Fw 190 with as many as two 7.6-millimetre machine guns and four 20-millimetre cannon, the P-47 eight .50-inch machine guns, and the F6F and P-51 six .50-inch machine guns. The Fw 190, P-47, and F6F had distinctively bulky fuselages widened to accommodate their twin-row radial

The Flying Fortress

The Battle of Britain

engines, while the slimmer P-51, designed in 1940 by J.H. ("Dutch") Kindleberger under a British contract, was fitted with in-line engines and incorporated the latest drag-reduction and airfoil data provided by NACA. Powered by the Rolls-Royce Merlin, the P-51 became the outstanding high-altitude escort fighter of the war. It was at least competitive with contemporary versions of the Spitfire, Bf 109, and Fw 190 in speed, rate of climb, and maneuverability, but it had a more spacious fuselage, a more efficient wing, and, fitted with droppable fuel tanks, a far greater radius of action of more than 1,000 miles. During 1943 the Soviet Red Air Force also gained technical parity with the Luftwaffe with its radial-engined Lavochkin La-5 and La-7 and the in-line-powered Yakovlev Yak-3 and Yak-9.

By war's end, piston-engined fighter technology reached its peak in later versions of the Fw 190, powered by in-line Jumo engines by Junkers, and in the Hawker Tempest, powered by the massive 2,200-horsepower, 24-cylinder, in-line Napier Sabre. Armed with four 20-millimetre cannon and able to attain speeds in excess of 435 miles per hour, the Tempest was the fastest piston-engined fighter ever to see service.

Night fighters. During the Battle of Britain, the RAF converted twin-engined bombers such as the Bristol Blenheim into night fighters by installing offensive ordnance and radar, but these had little success, since they were no faster than their prey. On the other hand, Messerschmitt's Me 110, a disastrous failure as a twin-engined, two-seat day fighter, became highly successful at night fighting, as did similarly modified Ju 88 bombers. The RAF later used radar-equipped versions of the de Havilland Mosquito to protect its bombers during the battle for the night skies over Germany in 1943–45.

Ground attack.   The most effective attack aircraft of the war was the Soviet Ilyushin Il-2 Stormovik. Heavily armoured for protection against ground fire and defended by a gunner in the rear of the two-seat cabin, the Il-2 could fly at up to 280 miles per hour at treetop level and was able to attack ground targets with cannons, bombs, and rockets. It was the first close-support type to employ rockets in vast quantities and had a great influence on the adoption of such weapons by other Allied forces. Another important ground-attack aircraft was Britain's Hawker Typhoon, originally intended to be a high-altitude fighter but limited to low altitudes by its thick wing. Armed with rockets and 20-millimetre cannon, it specialized in attacking trains, tanks, and other moving ground targets.

Bombers.   The Stuka dive-bomber was used to great effect during the invasions of Poland, France, and the Low Countries in 1939–40, but its slow speed rendered it vulnerable to fighter attack. The Germans' principal bombers of the Battle of Britain were the twin-engined Heinkel He 111, Dornier Do 17, and Ju 88. The Ju 88 was fast, with a top speed of 280 miles per hour, but it carried a modest bombload; the other German bombers had mediocre performance and were lightly armed by British or American standards. The later Do 217 had a range of 1,500 miles and could carry a bombload of 8,800 pounds, but it was built only in small numbers. The Germans never built a successful four-engined bomber.

Combat experience showed that the heavily armed British and U.S. bombers were more vulnerable to fighter attack than expected. This was dramatically revealed on Dec. 18, 1939, when a formation of Vickers Wellingtons—the most battle-worthy bombers of the day with four-gun Boulton Paul tail turrets—was decimated over the Heligoland Bight by cannon-armed German fighters. In time this led to the adoption of self-sealing fuel tanks, armour protection for crews, and even heavier defensive armament, but the British responded immediately by abandoning daylight bombing except under special circumstances. Bombing at night reduced vulnerability to fighters, but finding and hitting targets proved difficult: nothing smaller than a city could be effectively attacked, and, as operational analysis revealed in 1941–42, ordinary crews had trouble doing even that. The problem was solved partly by using specially trained "Pathfinder" crews to mark targets with flares and partly by electronic navigation aids. During the Battle of Britain, the Germans used electronic beams to

guide bombers to their targets at night, and the British later developed such on-board radars as the H_2S blind bombing system, which could produce maplike pictures of terrain beneath the aircraft through clouds or in darkness. From 1943, powerful four-engined bombers such as the Handley Page Halifax and Avro Lancaster, carrying H_2S radar and heavy armament, kept RAF bomber losses within barely acceptable limits.

An independent British development was the de Havilland Mosquito. Constructed entirely of wood, powered by two Rolls-Royce Merlin engines, and carrying a crew of two and no defensive armament, this extraordinarily fast aircraft remained effectively immune to interception until the appearance of jet fighters, and it could reach Berlin with a 4,000-pound bomb. It was perhaps the most successful multimission aircraft ever made, serving with distinction as a low-level day bomber, radar-equipped night fighter, and long-range photoreconnaissance aircraft.

The U.S. Army Air Force armed later versions of its B-17 Flying Fortresses and Consolidated-Vultee B-24 Liberators with 12 or more .50-inch machine guns, eight of them in twin-gun, power-driven turrets in nose, tail, ventral, and belly positions. Still, losses were high, reaching unacceptable numbers in raids against the Schweinfurt ball-bearing works on Aug. 17 and Oct. 14, 1943. Daylight bombing had to be curtailed until the arrival of P-38, P-47, and P-51 escort fighters equipped with drop tanks to provide the necessary range. For high-altitude attacks from 25,000 feet, the B-17 could carry 4,000 pounds of bombs at 215 miles per hour with a radius of action of some 800 miles. The B-24 carried more bombs and was slightly faster, but it could not fly as high and was more vulnerable to enemy fire. British heavy bombers carried larger bombloads—the Lancaster could carry 7,000 pounds with a radius of action of nearly 1,000 miles or a bombload of 14,000 pounds over a radius of 500 miles—but only at medium altitudes of less than 20,000 feet. The heaviest bomber of World War II was the Boeing B-29 Superfortress (see Figure 40), which entered service in 1944 with a fully pressurized crew compartment (previously used only on experimental aircraft) and as many as 12 .50-inch machine guns mounted in pairs in remotely-controlled turrets. Although these features were intended to optimize the B-29 for very high-altitude missions at 35,000 feet, it was most effectively used when, stripped of almost all its heavy defensive armament, it carried bombloads as heavy as 12,000 pounds in low altitude firebombing attacks against Tokyo and other Japanese cities from bases 2,000 miles away in the Mariana Islands. Specially modified B-29s dropped atomic bombs on Hiroshima and Nagasaki.

Figure 40: Boeing B-29 Superfortresses, U.S. long-range bombers built for the high-altitude bombing of Japan.

Naval aviation.   During World War II, carrier-based attack aircraft replaced the big guns of capital ships as the dominant offensive weapon of naval warfare. This was first demonstrated by the destruction of Italian battleships at Taranto by Fairey Swordfish torpedo biplanes on the night of Nov. 11–12, 1940; by the Japanese attack on Pearl Harbor on Dec. 7, 1941; and by the decisive Battle of Midway (June 3–6, 1942), in which surface vessels never exchanged gunfire while U.S. aircraft destroyed four Japanese aircraft carriers for the loss of only one of their

Margin notes:

Air power at sea

own. In addition to such fighters as the F6F, Zero, and modified Spitfires and Hurricanes, notable carrier aircraft of the war included dive-bombers such as the U.S. Douglas SBD Dauntless and Japanese Aichi 99 as well as torpedo planes such as the Grumman TBF Avenger and Nakajima B5N.

Land-based torpedo planes were also effective, as shown in attacks on the British battleships *Repulse* and *Prince of Wales* by twin-engine Japanese Mitsubishi G3M bombers off Malaya on Dec. 10, 1941.

Kamikaze attacks, a Japanese suicide tactic first used in the Battle of Leyte Gulf on Oct. 25, 1944, were very destructive as long as the supply of skilled volunteer pilots held out. First conducted with bomb-armed Zero fighters, they later expanded to encompass bombers and such special craft as a piloted, rocket-propelled winged bomb called the Ohka ("Cherry Blossom"). By the end of the war, however, there were no more skilled kamikaze volunteers, and the tactic became no more effective than traditional dive bombing.

Reconnaissance. For military staffs contemplating offensive operations, aerial photography became the most important source of detailed information on enemy dispositions. British reconnaissance aircraft were especially capable. Modified versions of the Spitfire and Mosquito, stripped of armament and fitted with extra fuel tanks, proved essentially immune to interception at high altitudes. Stripped-down versions of the P-38 and P-51, called the F-4 and F-5, were also effective photoreconnaissance platforms, the latter excelling at high-resolution coverage from low altitudes.

Training. Japan and Germany entered World War II with exceptionally well-trained aviators, but their provisions for training replacements were inadequate. The British Commonwealth and the United States gained a vital advantage over the Axis by establishing large, well-organized air-crew training programs. Outstanding training aircraft included the British de Havilland Tiger Moth, the U.S. Stearman PT-19, and the German Bücker Bü 133 Jungmeister—all biplanes. Only the United States built specialized single-engined trainers with such features characteristic of operational craft as retractable landing gear and variable-pitch propellers. Notable among these was the North American AT-6.

Air transport. Major advances in air transport were made during the war. Mass drops of parachute troops had been pioneered by the Soviet Union in the 1930s, but the Luftwaffe first used the technique operationally, notably during the invasion of Crete, in which 15,000 airborne and parachute troops were landed onto that island by 700 transport aircraft and 80 gliders. The troop-carrying glider was one of the developments of World War II that had no continuing place in postwar air forces, but the transport airplane was only at the beginning of its useful life. The Germans built transports such as the Ju 52 only in small quantities, but the twin-engined Douglas C-47, which had revolutionized American commercial aviation in the mid-1930s as the DC-3, was produced in huge numbers and was the backbone of tactical air transport in every Allied theatre of the war. One of the few transports with a large side door suitable for dropping paratroopers, the C-47 was also the mainstay of British and American airborne operations. Douglas also manufactured the four-engined C-54, which entered service in 1943–44 as the first land-based transport with intercontinental flight capabilities. The C-54 was particularly important in the vast distances of the Pacific-Asian theatre of operations.

The Douglas C-47

Helicopters. In the years before World War II, both the U.S. Army and the RAF had experimented with autogiros; these were craft that employed a propeller for forward motion and a freely rotating, unmotorized rotor for lift. In the event, autogiros proved too expensive and mechanically complex and were supplanted by conventional light aircraft. Meanwhile, during the late 1930s Igor Sikorsky in the United States and Anton Flettner and Heinrich Focke in Germany had perfected helicopter designs with serious military potential. The Sikorsky R-4, powered by a single lifting rotor and an antitorque tail rotor, was used for local rescue duties at U.S. air bases in the Pacific and

was also used in several combat rescues in Burma. The German navy used a handful of Flettner Fl 282s, powered by two noncoaxial, contrarotating lifting rotors, for ship-based artillery spotting and visual reconnaissance.

THE JET AGE

Beginning in the 1920s, steady advances in aircraft performance had been produced by improved structures and drag-reduction technologies and by more powerful, supercharged engines, but by the early 1930s it had become apparent to a handful of farsighted engineers that speeds would soon be possible which would exceed the capabilities of reciprocating engines and propellers. The reasons for this were not at first widely appreciated. At velocities approaching Mach 1, or the speed of sound (about 745 miles per hour at sea level and about 660 miles per hour at 36,000 feet), aerodynamic drag increases sharply. Moreover, in the transonic range (between about Mach 0.8 and Mach 1.2), air flowing over aerodynamic surfaces stops behaving like an incompressible fluid and forms shock waves; these in turn create sharp local discontinuities in airflow and pressure, creating problems not only of drag but of control as well. Because propeller blades, describing a spiraling path, move through the air at higher local velocities than the rest of the aircraft, they enter this turbulent transonic regime first. For this reason, there is an inflexible upper limit on the speeds that can be attained by propeller-driven aircraft. Such complex interactions in the transonic regime—and not the predictable shockwave effects of supersonic flight, which ballisticians had understood since the late 19th century—presented special problems that were not solved until the 1950s. In the meantime, a few pioneers attacked the problem directly by conceiving a novel power plant, the turbojet.

While still a cadet at the Royal Air Force College, Cranwell, in 1928, Frank Whittle advanced the idea of replacing the piston engine and propeller with a gas turbine, and in the following year he conceived the turbojet, which linked a compressor, combustion chamber, and turbine in the same duct. In ignorance of Whittle's work, three German engineers independently arrived at the same concept: Hans von Ohain in 1933; Herbert Wagner, chief structural engineer for Junkers, in 1934; and government aerodynamicist Helmut Schelp in 1937. Whittle had a running bench model by the spring of 1937, but backing from industrialist Ernst Heinkel gave von Ohain the lead. The He 178, the first jet-powered aircraft, flew on Aug. 27, 1939, nearly two years before its British equivalent, the Gloster E.28/39, on May 15, 1941. Through an involved chain of events in which Schelp's intervention was pivotal, Wagner's efforts led to the Junkers Jumo 004 engine. This became the most widely produced jet engine of World War II and the first operational axial-flow turbojet, one in which the air flows straight through the engine. By contrast, the Whittle and Heinkel jets used centrifugal flow, in which the air is thrown radially outward during compression. Centrifugal flow offers advantages of lightness, compactness, and efficiency—but at the cost of greater frontal area, which increases drag, and lower compression ratios, which limit maximum power. Many early jet fighters were powered by centrifugal-flow turbojets, but, as speeds increased, axial flow became dominant.

The first turbojets

Fighters. *Subsonic flight.* Though Whittle was first off the mark, the Germans advanced their programs with persistence and ingenuity. The Messerschmitt Me 262, powered by two Jumo engines and with wings swept back 18.5°, was capable of 525 miles per hour. Armed with four 30-millimetre cannon and unguided rockets, it was an effective bomber destroyer, but it entered service too late to have a major effect on the war. The Gloster Meteor entered service on July 27, 1944, about two months before the Me 262; though it was less capable than the German fighter, it was effective in intercepting V-1 "buzz bombs." Desperate to combat Allied bombers, the Germans also turned to rocket propulsion, fielding the tailless Me 163 Komet in the final months of the war. Powered by a hydrogen peroxide rocket designed by Helmuth Walter, the Komet had spectacular performance, but its short range and ineffective cannon armament made it an operational

failure. In addition, the propellants were unstable and often exploded on landing.

Meanwhile, the U.S. aviation industry entered the jet race with the receipt by General Electric of a Whittle engine in 1941. The first U.S. jet, the Bell P-59A Airacomet, made its first flight the following year. It was slower than contemporary piston-engined fighters, but in 1943–44 a small team under Lockheed designer Kelly Johnson developed the P-80 Shooting Star. The P-80 and its British contemporary, the de Havilland Vampire, were the first successful fighters powered by a single turbojet.

The jets of World War II inaugurated the first generation of jet fighters, in which turbojet propulsion was applied to existing airframe technology and aerodynamics. (Indeed, some early postwar jets—notably, the Soviets' Yakovlev Yak-15 and Yak-23 and the Swedish Saab 21R—were simply re-engined propeller-driven fighters.) These aircraft generally outperformed their piston-engined contemporaries by virtue of the greater thrust that their jets provided at high speeds, but they suffered from serious deficiencies in range and handling characteristics owing to the high fuel consumption and slow acceleration of early turbojets. More fundamentally, they were limited to subsonic speeds because the relatively thick airfoils of the day were prone to the compressibility problems of transonic flight—especially at high altitudes, where the higher speeds required to produce lift in thin atmosphere brought aircraft more quickly to transonic speed. For this reason, first-generation jets performed best at low altitudes.

Other first-generation fighters included the U.S. McDonnell FH Phantom and the British Hawker Sea Hawk (the first jet carrier fighters), the McDonnell F2H Banshee, and the French Dassault Ouragan. These single-seat day fighters were in service by 1950, while first-generation all-weather fighters, burdened with radar and a second crew member, entered service through the late 1950s.

Transonic flight. As the first generation of jet fighters entered service, many aerodynamicists and engineers believed supersonic flight a practical impossibility, owing to transonic drag rise or compressibility, which threatened to tear an aircraft apart. Nevertheless, on Oct. 14, 1947, U.S. Air Force Captain Charles Yeager, flying a rocket-powered Bell X-1 launched from the bomb bay of a B-29, became the first human to exceed the speed of sound. Designed exclusively for research, the X-1 had thin, unswept wings and a fuselage modeled after a .50-inch bullet. Yeager's flight marked the dawn of the supersonic era, but it was only part of a broad wave of testing and experimentation that had begun during World War II. Germany had experimented then with swept-back and delta-shaped wings, which delayed transonic drag rise, and, after extensive testing, these configurations were widely adopted in the postwar years. At the same time, the development of slats, slotted flaps, and other sophisticated high-lift devices for landing and takeoff enabled designers to use smaller wings, which in turn allowed them to achieve higher speeds. Turbojets became more powerful, and, in the late 1950s, afterburning, or reheat, was introduced; this permitted large temporary thrust increases by the spraying of fuel into hot exhaust gases in the tailpipe—in effect turning the turbojet into a ramjet.

As these developments took hold, a second generation of fighters appeared that were capable of operating in the transonic regime. These aircraft had thinner lifting and control surfaces than first-generation jets, and most had swept-back wings. Aerodynamic refinements and more powerful, quicker-accelerating engines gave them better flight characteristics, particularly at high altitudes, and some could exceed the Mach in a shallow dive. In addition, airborne radars became more compact and reliable, and radar-ranging gunsights began to replace the optically ranging sights used in World War II. Air-to-air missiles, using radar guidance and infrared homing, became smaller and more capable (see above *Rockets and missile systems: Tactical guided missiles*). Outstanding fighters of this generation were the U.S. North American F-86 Sabre and its opponent in the Korean War (1950–53), the Soviet MiG-15. The F-86 introduced the all-flying tail (later a standard feature on high-performance jets), in which the entire hor-

Limitations of early jet fighters

The F-86 and MiG-15

izontal stabilizer deflects as a unit to control pitch, yielding greater control and avoiding the compressibility problems associated with hinged surfaces. This and a radar-ranging gunsight helped the F-86 achieve a favourable kill ratio over the MiG-15, despite the Soviet fighter's greater speed, higher service ceiling, and heavier armament. Other jets of this generation were Britain's superlative Hawker Hunter, the MiG-17, and the diminutive, British-designed Folland Gnat. The latter two, introduced in the mid-1950s, later became successful low-altitude dogfighters—the Gnat against Pakistani F-86s in the Indo-Pakistani conflict of 1965 and the MiG-17 against U.S. aircraft in the Vietnam War (1965–73).

Supersonic flight. A third generation of fighters, designed around more powerful, afterburning engines and capable of level supersonic fight, began to enter service in the mid-1950s. This generation included the first fighters intended from the outset to carry guided air-to-air missiles and the first supersonic all-weather fighters. Some were only marginally supersonic, notably the U.S. Convair F-102 Delta Dagger, an all-weather interceptor that was the first operational "pure" delta fighter without a separate horizontal stabilizer. Other aircraft included the Grumman F11F Tigercat, the first supersonic carrier-based fighter; the North American F-100 Super Sabre; the Dassault Mystère B-2; the Saab 35, with a unique double-delta configuration; and the MiG-19.

To this point, jet fighters had been designed primarily for air-to-air combat, while older aircraft and designs falling short of expectations were adapted to ground attack and reconnaissance. Since land-based surface attack was to be carried out by bombers, the first operational jets of fighter size and weight designed to attack surface targets were based on aircraft carriers. These paralleled the third generation of fighters, but they were not supersonic. One example was the British Blackburn Buccaneer, capable of exceptional range at low altitudes and high subsonic speeds. The Douglas A-4 Skyhawk, entering service in 1956, sacrificed speed for ordnance-delivery capability. One of the most structurally efficient aircraft ever built, it carried the burden of U.S. Navy attacks on ground targets in North Vietnam and was often used by Israeli pilots in the Middle Eastern conflicts. The Grumman A-6 Intruder, which entered service in the 1960s, was another subsonic carrier-based aircraft. The first genuine night/all-weather, low-altitude attack aircraft, it was highly successful over North Vietnam.

Mach 2. A fourth generation of fighters began to appear in the 1960s, capable of maximum speeds ranging from about Mach 1.5 to 2.3. Top speeds varied with the intended mission, and increasing engine power, aerodynamic sophistication, and more compact and capable radars and avionics began to blur the differences between two-seat, all-weather fighters and single-seat air-superiority fighters and interceptors. By this time, military designers had become persuaded that air-to-air missiles had made dogfighting obsolete, so that many interceptors were built without guns. This generation included the first land-based jet fighters designed with surface attack as a secondary or primary mission—a development driven by the appearance of surface-to-air missiles such as the Soviet SA-2, which denied bombers medium- and high-altitude penetration.

Precursor to this generation was the Lockheed F-104 Starfighter, designed by a team under Kelly Johnson and first flown in 1954. Capable of speeds well above Mach 2, this interceptor was built with short and extremely thin wings to reduce the generation of shock waves. However, light armament, limited avionics, and poor maneuverability made it an ineffective air-to-air fighter, and only with the installation of up-to-date bombing and navigation systems in the 1960s did it become a useful low-level attacker. The truly outstanding fighters were the U.S. McDonnell F-4 Phantom II and the MiG-21. A large, twin-engined two-seater, the F-4 was originally a carrier-based interceptor armed only with air-to-air missiles, but it was so successful that the U.S. Air Force adopted it as its primary fighter. When combat in Vietnam showed that gun armament was still valuable for close-range dogfight-

Ground-attack jets

The F-4 and MiG-21

ing, later versions of the F-4 were fitted with an internally mounted, 20-millimetre rotary cannon. The MiG-21 was a small, delta-wing, single-seat aircraft designed as a specialized daylight interceptor, but it soon proved amenable to modification for a broad range of missions and became the most widely produced jet fighter ever. It was a formidable threat to U.S. airmen over North Vietnam and to Israeli pilots over the Sinai Peninsula and Golan Heights in 1973. Also outstanding was the Republic F-105 Thunderchief, one of the largest single-engined fighters ever built. Designed to carry a nuclear bomb internally as a low-altitude penetrator and therefore exceptionally fast at low altitudes, the F-105, with heavy loads of conventional bombs under the wings, carried out the brunt of U.S. Air Force attacks against North Vietnam. Also noteworthy in this generation were the British Electric Lightning, one of the first Mach-2 interceptors to enter service and one of the fastest at high altitudes; the Soviets' twin-engined, all-weather Yak-28 Firebar; the Convair F-106 Delta Dart, a single-seat air-defense interceptor with superior speed and maneuverability; the Dassault Mirage III, the first successful pure delta in the air-to-air role and an enormous export success; the Soviet Sukhoy Su-21 Flagon, a tailed-delta, single-seat, all-weather interceptor; and the Vought F-8 Crusader, an outstanding carrier-based dogfighter over Vietnam.

Multimission. By the 1970s, steady improvements in engine performance, aerodynamics, avionics, and aircraft structures resulted in a trend toward multimission fighters. Also, as engine acceleration characteristics improved dramatically and radars, fire-control systems, and air-to-air missiles became more compact and capable, the performance of aircraft themselves became less important than the capabilities of their missiles and sensors. It was now clear that, even with supersonic aircraft, almost all aerial combat occurred at transonic and subsonic speeds. Thenceforth, speed and operating ceiling were traded off against sustained maneuvering energy, sensor capabilities, mixed ordnance of guns and missiles, range, takeoff and landing qualities, multimission capability, political goals, and—above all—cost. A dramatic manifestation of the complexity of this new design equation was the Hawker Harrier, the first vertical/short takeoff and landing (V/STOL) fighter. Transonic and short-ranged but able to dispense with runways, the Harrier became operational with the RAF in 1967 and over the following decades was fitted with avionics of growing capabilities. The Royal Navy's Sea Harrier version (see Figure 41) distinguished itself in the 1982 Falkland Islands War both against Argentine ground positions and in dogfights with A-4s and Mirage IIIs.

The new generation of fighters was characterized by Mach 2+ performance where necessary, multimission capability, and sophisticated all-weather avionics. Many aircraft of this generation employed variable-geometry wings, permitting the amount of sweep to be changed in flight to obtain optimal performance for a given speed. Important aircraft in this generation included, roughly in order of operational appearance, the following: the MiG-25 Foxbat, a large single-seat interceptor and reconnaissance aircraft with a service ceiling of 80,000 feet and a top speed on the order of Mach 2.8 but with limited maneuverability and low-altitude performance; the MiG-23 Flogger, a variable-wing interceptor able to acquire and engage with missiles below it in altitude; the MiG-27 Flogger, a ground-attack derivative of the MiG-23; the Saab 37 Viggen, designed for short takeoff with a main delta wing aft and small delta wings with flaps forward; the fixed-wing Sepecat Jaguar, developed by a French-British consortium in ground-attack and interceptor versions; the Grumman F-14 Tomcat, a highly maneuverable, twin-engined, two-seat, variable-geometry interceptor armed with long-range missiles for the defense of U.S. aircraft-carrier fleets; the Dassault-Breguet Mirage F1, designed for multimission capability and export potential; the McDonnell Douglas F-15 Eagle, a single-seat, twin-engined, fixed-geometry air-force fighter designed for maximum sustained maneuvering energy and the first possessor of a genuine "look-down/shoot-down" capability, which was the product of pulse-Doppler radars that could detect fast-moving targets against cluttered radar reflections from the ground; the Panavia Tornado, a compact, variable-geometry aircraft developed jointly by West Germany, Italy, and Great Britain in no fewer than four versions, ranging from two-seat, all-weather, low-altitude attack to single-seat air-superiority; the U.S. General Dynamics F-16 Fighting Falcon (see Figure 41), a high-performance, single-seat multirole aircraft with impressive air-to-ground capability; the MiG-29 Fulcrum, a single-seat, twin-engined, fixed-geometry interceptor with a look-down/shoot-down capability; the MiG-31 Foxhound interceptor, apparently derived from the MiG-25 but with less speed and greater air-to-air capability; and the McDonnell Douglas F/A-18 Hornet, a single-seat, carrier-based aircraft designed for ground attack but also possessing excellent air-to-air capability.

Bombers. *High-altitude craft.* The Luftwaffe fielded the first operational jet bomber, the Arado Ar 234, in the waning months of World War II, but it had minimal impact. The jet bombers of the immediate postwar years enjoyed only indifferent success, mostly serving to test engineering and operational concepts and being produced in small numbers. By the mid-1950s, however, first the Americans and then the British and Soviets began to field highly capable jet bombers. The first of these to be produced in large numbers was the swept-wing, six-engined Boeing B-47 Stratojet, used by the U.S. Strategic Air Command as a long-range nuclear weapons carrier. Deployed in 1950, it was followed in 1955 by the eight-engined Boeing B-52

Stratofortress. This huge bomber, 153 feet long and with a wing span of 185 feet, remained the principal long-range nuclear weapons carrier of the United States for 30 years. During the Vietnam War it dropped conventional bombs on both tactical and strategic missions, and in the 1980s it received a new lease on life by being fitted with airlaunched cruise missiles, which permitted it to threaten targets from beyond the range of air-defense systems.

The British "V-bombers," introduced in the 1950s, comprised the Vickers Valiant, Handley Page Victor, and Avro Vulcan. These served as the backbone of Britain's nuclear deterrent until superseded by Polaris-missile-equipped nuclear submarines in the 1970s. The Vulcan, the first jet bomber to use the delta-wing configuration, remained in service long enough to drop conventional bombs in the Falkland Islands War.

The first Soviet jet bombers with strategic potential were the twin-engined Tupolev Tu-16 Badger (deployed in 1954) and the larger and less successful four-engined Myasishchev M-4 Bison (deployed in 1956). In 1956 the Soviets also fielded the only turboprop strategic bomber to see service, the Tu-95 Bear. A large, swept-wing aircraft powered by four huge turboprop engines with contrarotating propellers, the Tu-95 proved to have excellent performance. Like the B-52, it was adapted to maritime and cruise missile patrol after it had become obsolete as a strategic bomber.

The aircraft mentioned above were capable of only subsonic speeds. The first operational supersonic bomber was the delta-winged Convair B-58 Hustler of the United States. Placed in active service in 1960, this bomber carried its nuclear weapon and most of its fuel in a huge, jettisonable pod beneath the fuselage.

Low-level penetration. The B-58 had a service life of only three years, because in the early 1960s it became apparent that surface-to-air missiles could shoot down aircraft even at previously safe altitudes of over 50,000 feet. In response, bombers sought protection from early-warning radar by flying at low levels, and a new generation of high-performance bombers came into service that took complete advantage of the propulsion, aerodynamic, and electronic advances of the postwar era. The first of these was the U.S. General Dynamics F-111, the first operational aircraft to use a variable-sweep wing. Variable geometry was originally intended to allow the F-111 to combine the missions of low-altitude bomber and high-altitude fleet-defense fighter, but the fighter version was eventually abandoned. After a poor showing in Indochina in 1968, the F-111 became a successful high-speed, low-

altitude, all-weather penetrator. As such, it joined with considerable effect in the final stages of the U.S. aerial offensive on North Vietnam, and it was also assigned to NATO as a tactical-range nuclear weapons carrier. The Soviet Su-24 Fencer was similar to the F-111.

Larger strategic bombers using variable geometry to achieve high performance at low altitudes included the Soviet Tu-26 Backfire, the U.S. Rockwell International B-1, and the Tu-160 Blackjack. These bombers, supplementing the older purely subsonic aircraft, formed an important part of the U.S. and Soviet nuclear forces after their deployment in 1975, 1985, and 1988, respectively. In common with all first-line combat aircraft, they were equipped with sophisticated electronic countermeasure (ECM) equipment designed to jam or deceive enemy radars. They could deliver free-fall conventional or nuclear bombs, air-to-surface missiles, and cruise missiles. The B-1B version (see Figure 42) could achieve supersonic flight only in short bursts at high altitude, while the Soviet bombers were capable of supersonic "dash" at low level and could fly at twice the speed of sound at high altitude. *(margin: The B-1 and Tu-26)*

Stealth. *The first operational craft.* The existence of a Stealth program, designed to produce aircraft that were effectively immune to radar detection at normal combat ranges, was announced by the U.S. government in 1980. The first aircraft employing this technology, the single-seat Lockheed F-117A ground-attack fighter, became operational in 1983. The second was the Northrop B-2 strategic bomber, which first flew in 1989. Both aircraft had unconventional shapes that were designed primarily to reduce radar reflection. The B-2 was of a flying-wing design that made it only slightly longer than a fighter yet gave it a wingspan approaching that of the B-52, while the F-117A had a short, pyramid-shaped fuselage and sharply swept wings.

Stealth technology. Ever since radar-directed defenses began taking a toll of bomber formations in World War II, aircraft designers and military aviators had sought ways to avoid radar detection. Many materials of the early jet age were known to absorb radar energy rather than reflect it, but they were heavy and not strong enough for structural use. It was not until after the 1960s and '70s, with the development of such materials as carbon-fibre composites and high-strength plastics (which possessed structural strength as well as being transparent or translucent to radar), that radar signature reduction for piloted combat aircraft became possible.

Reducing radar signature also required controlling shape, particularly by avoiding right angles, sharp curves, and large surfaces. In order to direct radar energy in the least revealing directions, the external shape of a stealth aircraft was either a series of complex, large-radius, curved surfaces (as on the B-2) or a large number of small, flat, carefully oriented planes (as on the F-117A). Fuel and ordnance were carried internally, and engine intakes and exhausts were set flush or low to the surface. To avoid interception of radar emissions, stealth aircraft had to rely on inertial guidance or other nonemitting navigational systems. Other possibilities included laser radar, which scanned the ground ahead of the craft with a thin, almost undetectable laser beam. *(margin: Reducing radar reflectivity)*

To escape detection in the infrared spectrum, stealth aircraft were not equipped with large, heat-producing afterburner engines. This rendered them incapable of supersonic flight. Also, the shapes and structures optimal for stealth aircraft were often at odds with aerodynamic and operational requirements. Since all weaponry had to be carried internally, ordnance loads were less than for equivalent conventional aircraft, and sophisticated artificial stabilization and control systems were needed to give stealth aircraft satisfactory flying characteristics. Unlike the fighter, the B-2 had no vertical fin stabilizers, relying on flaps on the trailing edge of its notched wing to control roll, pitch, and yaw.

Other military aircraft. *Transport.* The success of the C-47 and C-54 in World War II inspired the development of specialized military freighters with nose- and tail-loading features, roller conveyors on the floor, and built-in winches. These permitted the quick loading of vehi-

CTK from Eastfoto

cles and large equipment as well as their air-dropping by parachute. Military transports ranged from small V/STOL liaison aircraft and modified versions of civilian transports to huge craft such as the Lockheed C-5 Galaxy, designed in the 1960s to carry two M-60 tanks, 16 three-quarter-ton trucks, or 245 troops. After its introduction in 1969, the C-5 was the largest aircraft in the world for almost two decades, until it was surpassed by the Soviet Antonov An-225. With a cargo bay 21 feet wide, 14.5 feet high, and 140 feet long, the An-225 was designed to carry a payload of as much as 440,800 pounds.

Reconnaissance. Reconnaissance aircraft also carried ECM devices and relied heavily on electronic and infrared sensors to supplement their film cameras. Their tasks were to locate and photograph targets, using radar and conventional photographic techniques, and to probe enemy electronic defense systems to discover and evaluate the types of radio and radar equipment that were in use. They did this by offshore patrols just outside territorial limits and, more rarely, by overflights. The best-known American types used for overflights were two Lockheed aircraft—the U-2, first flown in the mid-1950s, and the SR-71 Blackbird, which came into service in the mid-1960s. The U-2, built of aluminum and limited to subsonic flight, could cruise above 70,000 feet for very long periods. The SR-71 had a titanium airframe to resist the heat generated by flying at Mach 3; this aircraft could operate above 80,000 feet.

The U-2

Airborne early warning. Carrier-based early-warning aircraft had a large radar to detect aircraft or ships; some could also control interceptor fighters defending the fleet. This kind of airborne warning and control system (AWACS) airplane appeared in land-based air forces to detect low-flying enemy raiders and direct interceptors toward them. The first aircraft of this type was a Soviet turboprop, the Tu-126 Moss, which was succeeded in the 1980s by the jet-powered Ilyushin Il-76 Mainstay. These craft, like the U.S. E-3 Sentry (a converted Boeing 707), carried a large, saucer-shaped radar on the fuselage. Britain's early-warning aircraft was the British Aerospace Nimrod.

Helicopters. The helicopter had its first significant impact on military operations during the Korean War, but it came of age in Vietnam. Helicopters fielded air-mobile infantry units, evacuated casualties, hauled artillery and ammunition, rescued downed aviators, and served as ground-attack craft. Helicopters became serious operational machines only after American manufacturers fitted them with gas-turbine engines, which were much less sensitive than piston engines to high temperatures and low atmospheric density, had far greater power-to-weight ratios, and occupied considerably less space.

Assault and attack helicopters. The mainstay of U.S. Army assault units in Vietnam was the Bell UH-1 Iroquois, popularly known as the Huey. As early as 1962, army aviators added turret-mounted automatic 40-millimetre

grenade launchers, skid-mounted rocket pads, and remotely trainable 7.62-millimetre machine guns. These experiments, which proved effective in supporting helicopter assault operations, led to the AH-1G HueyCobra, deployed in 1967 as the first purpose-built helicopter gunship. With its pilot seated behind and above the gunner, the HueyCobra pioneered the tandem, stepped-up cockpit configuration of future attack helicopters.

After the Vietnam War, the lead in gunship design passed to the Soviet Union, which, in the Afghan War of the 1980s, fielded the Mil Mi-24 Hind, the fastest and possibly most capable helicopter gunship of its time (see Figure 43). A primary role of the Hind was to attack armoured vehicles; to this end, it mounted guided antitank missiles on stub wings projecting from the fuselage. In addition to the two-man cockpit configuration of the HueyCobra, it had a small passenger and cargo bay that gave it a limited troop-transport capability.

The Mi-24 Hind

The successor to the HueyCobra was the McDonnell Douglas AH-64 Apache, a heavily armoured antiarmour helicopter with less speed and range than the Hind but with sophisticated navigation, ECM, and fire-control systems. The Apache became operational in 1986. Soon afterward the Soviets produced the Mi-28 Havoc, a refinement of the Hind that, with no passenger bay, was purely a gunship.

Naval helicopters. Helicopters were used extensively in antisubmarine roles, "dipping" sonar sensors into the water to locate their targets and launching self-homing torpedoes to destroy them. Ship-borne helicopters also served as firing platforms for antiship missiles and were used to carry warning and surveillance radars, typically sharing information with their mother ships. By firing heat-producing or chaff flares to confuse infrared and radar homing systems, naval helicopters could serve as decoys for antiship missiles.

Remotely piloted vehicles. The first remotely piloted vehicles (RPVs) were small, pilotless aircraft controlled by command radio transmission. Most of these fell into one of two categories: extremely high-performance drones used to test new systems; and small, relatively inexpensive drones used for training. Both were typically reusable, being recovered by radio-controlled landing or, more commonly, by parachute. Target drones were commonly fitted with radar reflectors to stimulate the radar return of enemy aircraft, and it soon occurred to strategists to use them as decoys to assist bombers in penetrating enemy defenses. That modified target drones might be effective platforms for communications relay and for sensor and reconnaissance systems also became evident. The Ryan QM-34 Firebee, a photoreconnaissance modification of a standard U.S. target drone, saw extensive service in Vietnam. A swept-wing, turbojet-powered subsonic vehicle less than half the size of a jet fighter, the Firebee penetrated heavily defended areas at low altitudes with impunity by virtue of its small radar cross section and brought back strikingly clear imagery. Indicative of later development was the Boeing Compass Cope, a long-winged, subsonic, turbofan-powered drone capable of long flights at extremely high altitudes. (J.W.R.T./J.F.G.)

Warning and detection systems

Because military tactics from time immemorial have stressed the value of surprise—through timing, location of attack, route, and weight and character of arms—defenders have sought to construct warning systems to cope with all these tactics. Many types of warning systems exist. Long-term, or political, warning systems employ diplomatic, political, technological, and economic indicators to forecast hostilities. The defender may react by strengthening defenses, by negotiating treaties or concessions, or by taking other action. Political warning, equivocal and incapable of disclosing fully an attacker's intention, often results in an unevaluated and neglected situation.

Medium-term, or strategic, warning, usually involving a time span of a few days or weeks, is a notification or judgment that hostilities may be imminent. Short-term, or tactical, warning, often hours or minutes in advance, is a notification that the enemy has initiated hostilities.

Warning and detecting are separate functions. The sensors or detection devices perceive either the attack, the possibilities of an attack, the nearness of the enemy, his location, his size, his activities, his weapon capability, or some changes in his political, economic, technical, or military posture.

Warning systems include detection devices but also imply the judgments, decisions, and actions that follow receipt of the sensor's information. Warning encompasses communications, analysis of information, decisions, and appropriate actions. Visual observation still remains important, supplemented by telescopes, cameras, heat-sensing devices, low-light-level devices, radar, acoustic, seismic, chemical, and nuclear detection devices. The product, or output, of these sensors is complicated and voluminous and requires computers to condense and summarize the data for the decision maker. Often, the most expensive portion and weakest link of the warning system is not the sensor but the communication and evaluation systems. Technology of all types is required in modern warning systems.

HISTORY

History abounds with examples of successful military surprises; examples of effective warning are difficult to find. Military training emphasized the value of surprise, stratagem, and deception, but the value of warning was long neglected. Flank and rear guards, to protect marching columns, patrols and scouts to locate the enemy, and sentries to guard camps, were of course used in war from earliest times. Animals were sometimes employed to detect the approach of an enemy; dogs and horses were especially favoured, though, according to the ancient historian Livy, the Romans used geese to detect the night attack of the Gauls on Rome in the 4th century BC. High ground, favourable for observation, was often supplemented by watchtowers, such as those placed along the Great Wall of China and on Hadrian's Wall in Britain.

The observation balloon was an important technological advance. First used in warfare by the French in the late 18th century, primarily for offensive reconnaissance on the battlefield, its defensive possibilities were demonstrated in the American Civil War; in May 1863 a balloon of the army of the Potomac detected Lee's army moving from its camp across the Rappahannock to commence the Gettysburg campaign. Aerial photography had already been pioneered by the French and used in the War of Italian Independence (1859).

A balloon observer in the Spanish-American War of 1898 is credited with discovering an alternate route up San Juan Hill during the battle there. A few other successes are ascribed to such observation before the balloon was supplemented by the far more valuable airplane in World War I. Nevertheless, the balloon never fulfilled its potential as a warning device.

In sea warfare, warning and detection were equally neglected. As far back as the Minoan civilization of Crete, patrol ships were used, but mainly for offensive purposes. In later centuries, raised quarterdecks and lookout posts atop sailing masts were provided, but the beginnings of serious maritime detection technology did not come until the advent of the submarine.

Binoculars, telescopes, the telegraph, and telephone were well established military equipment by 1914; the airplane, first used by the Italians in the Italo-Turkish War of 1911, showed its potential as an observation device at the Battle of the Marne. Radio communications provided the means to make air observations immediately available. Aerial combat became inevitable as each side tried to deny the other its aerial reconnaissance.

Searchlights, first used in the Russo-Japanese War (1904), saw large-scale use in World War I to detect dirigibles and aircraft on night bombardment missions. Flares were used to illuminate the battlefield between trenches to detect raiding parties. Listening devices, using directional horns to detect and locate enemy aircraft, were also used with limited success.

Despite the novelties of World War I, World War II produced far more technological innovation. Radar made obsolete the slow and inaccurate older listening devices.

(margin) Balloon reconnaissance and aerial photography

(margin) The first observation airplanes

Radio communications made great strides, particularly in the very high frequency range. The combination of radar and interference-free very high frequency communications was pivotal in permitting the RAF to resist Hitler's aerial attack and win the Battle of Britain.

Notwithstanding radar sophistication, ground spotters played an important role in filling the gaps between radar coverage. Their messages, forwarded to a plotting centre, were assembled to trace the progress of intruders (tracking).

The advent of nuclear weapons (1945), especially when coupled later with the speed and range of intercontinental missiles, gave new dimensions to the value of surprise for the attacker. Long-term warning was suddenly of paramount importance. Not only did all forms of unequivocal warning become indispensable but the warning had to be made credible to an aggressor; that is, an assurance had to be given that the retaliatory weapons would not all be destroyed by a first strike. Bomber aircraft were kept in the air to avoid destruction on the ground and attempts were made to provide a degree of protection for the civilian population through shelters.

Practically all aspects of science and technology have been introduced into today's warfare and warning systems: airplanes, helicopters, submarines, earth satellites, television, lasers, and magnetic, acoustic, seismic, infrared, nuclear, and chemical detectors.

ELECTROMAGNETIC SENSORS

Modern detector technology. *The visible region.* Binoculars and telescopes have changed very little. Where vibration and motion create interference, gyroscopically stabilized optics are used in surface vehicles, ships, and aircraft.

Newer in character are the image intensifiers used for nighttime detection (see Figure 44). These devices receive the moonlight or starlight reflected from targets on a sensitive screen, amplify the image electronically, and present it at much higher light level on a small cathode-ray tube similar to that used in a television receiver. Typical of these devices is the starlight scope, resembling an oversized telescopic sight, with which riflemen can aim at night at 1,000–1,300 feet range. Artillery, tanks, helicopters, and aircraft use similar, larger devices having longer range. In aircraft the direct-viewing device is replaced by a cathode-ray tube in the instrument panel; this version is called low-light-level television.

Ordinary searchlights can often be used at night even in combat situations; but, to avoid drawing fire, invisible light, in the ultraviolet or near infrared range, can be used with appropriate viewing devices. Conventional photography, used in aerial reconnaissance and essential to long-term warning, must have high resolution despite temperature and vibration interference. To cover wide

(margin) The starlight scope

Figure 44: The night observation device, which provides a high degree of night vision capability to detect, locate, and identify the enemy. Using image intensification techniques, the low-light-level illumination of the night sky (*i.e.*, moonlight) reflected from the object and its background form a clearly defined image to the observer.

areas, panoramic cameras, scanning from side to side, record high-quality images. Frame cameras are also used, especially for mapping. At night, flares or flashing lights on aircraft are used.

Infrared. Infrared sensors on the ground, or in aircraft or spacecraft, can detect such hot spots as motor-vehicle engines, hot jet engines, missile exhausts, even campfires. They have good location accuracy and high sensitivity to signals, without registering such false targets as sun reflections.

In the very near infrared region, infrared imaging detectors use specially sensitized photographic film to reveal forms hidden by camouflage. More important are the detectors used in the far infrared region; objects at room temperature radiate sufficient energy for detection at ranges of several miles. Infrared imagery can have longer range than image intensifiers and can operate without starlight. When the humidity is high, the effective range is reduced.

The sniperscope, an early device that used infrared illumination and an infrared viewer, has been largely replaced by the image intensifier and by laser illuminators.

Radar. Radar is used by ground forces for many purposes: in portable sizes, for infiltration detection; in intermediate sizes, for mortar and artillery shell tracking; and in large sizes, for early warning, search, and control of air-defense weapons (interceptors and surface-to-air missiles).

Radar is used in fighter aircraft for finding enemy aircraft and controlling air-to-air missiles, rockets, and guns. It is used in bombers to find surface targets, fixed or moving, and to navigate and avoid obstacles. It is used in large aircraft as an airborne warning and control system, searching the skies over great distances for enemy aircraft, tracking them, and controlling interceptors. It also is used to search the seas for surface vessels or surfaced submarines. Radar also can be used in spacecraft to locate patterns of activity.

In all applications of radar, clutter in the form of reflections from surface objects or the terrain, or the disturbed sea, competes with reflection from the targets and must be cancelled by appropriate circuitry. Side-looking radars are used to obtain higher resolution than conventional radar, improving the ability to recognize surface targets.

Conventional radar operates at microwave and ultrahigh frequencies that propagate in straight lines like light rays; consequently, they cannot ordinarily detect objects beyond the Earth's horizon. Because high-frequency waves reflect from the ionosphere, over-the-horizon radars have been built to operate in this region.

Radio sensors. Radio receivers can be used to detect and locate enemy radio. Enemy radars can be located in much the same way. Messages can be intercepted. This form of warning has been combated by radio silence and by spoofing, the transmission of signals intended to deceive. In 1967 the Israelis transmitted voluminous radio messages from empty airfields to hide the fact that aircraft had been moved to other locations.

Radio direction finders can be used to locate nuclear bursts, because the explosion generates a large amount of energy in the radio frequency region.

Acoustic techniques. While electromagnetic waves do not propagate well under water, acoustic waves do and can be used to detect submerged submarines. These detection systems, called sonar, may intercept propeller or other noise generated by the submarine or may send out sounds and receive echoes from the submarine hull. Sonar devices can be operated aboard surface ships, aboard submarines, on floating sonobuoys, or suspended by cables from helicopters and dunked in the ocean.

Sonar systems are limited in range by attenuation (weakening) of the sound energy in water, bending caused by temperature differences in water layers, and extraneous noises, including reflections from the sea bottom.

Acoustic receivers are also used on land in sensors deployed near trails to detect the presence of personnel or vehicles along roads. The sounds are sent by radio to listening posts. Acoustic sensors are also used in monitoring nuclear explosions.

Seismic detectors. Seismic detectors (see Figure 45)—as well as underground acoustic detectors called geophones—are used in sensors for infiltration and vehicle detection.

Margin notes (left column):
Over-the-horizon radar

Sonar systems
Figure 45: *Distant sensing and identification.*
The acoustic sensing device is buried in the ground as shown. It detects movement of people and vehicles by sensing vibrations they cause in the earth and transmits a code to a special radio receiver.

Both types must be used, since either alone can yield false signals caused by the movement of animals.

Magnetic detectors. Sensitive magnetic detectors (magnetometers), flown in aircraft over the sea, are used to detect submarines because the large metallic mass of the submarine hull disturbs the earth's magnetic field. Buried on land, magnetometers are used to detect the passage of vehicles.

Nuclear detectors. Underground nuclear explosions are detected by sensitive seismometers. To increase the sensitivity and reject natural earth tremors, seismometers are often used in large arrays extending for hundreds of miles.

For atmospheric or space explosions, radio-pulse receivers and light flash and acoustic detectors are used, as well as devices to measure fallout. Aircraft and rockets can be used to collect radioactive debris, while high-altitude satellites carry detectors for gamma rays and other emissions.

Chemical sensors. Concealed chemical sensors, sensitive to minute amounts of body products, are capable of detecting personnel from short distances.

Future developments. Certain trends can be seen in sensor development for future warning systems. Infrared detectors of higher sensitivity and resolution are being developed. Higher-powered and smaller lasers will aid night warning systems. These and other lines of research, centred on lighter weight and more efficient optics and on more efficient detectors, should result in much cheaper systems with resolution approaching visual sensors. Perhaps most important are improvements in the resolution and brightness of the display—the chief limitation of most night viewing systems.

Photography has already reached an advanced state of technology, yet improvements in resolution are being actively pursued. Lightweight optics, more sensitive and fine-grained film, film that can be developed quickly by heat, and better compensation for the motion of the aircraft are some of the areas where photography can be improved.

Developments in large ground radars centre around the phased array radar having electronically steered beams. The beams must be computer-controlled. Moving target discrimination and Doppler processing are built out of digital circuitry as used in digital computers. This permits sensitive discrimination and rapid response.

The advent of the transistor and solid-state microcircuits is making small radars for infantrymen and tank operators possible. The miniature components and high reliability of these devices makes extremely complex and sophisticated circuitry possible.

Airborne radar is in its early stages of development. Side-looking Doppler-processing radar has already yielded high

resolution, but not quite as good as conventional photography. Developments in progress indicate that soon images comparable to photographic images will be obtained from airborne radar. Imperfections now common in radar imagery should be removed as a result of present research.

A great deal of effort in several countries has reduced the vulnerability of radars to electronic countermeasures; at the same time, however, similar improvements in electronic jamming and deception have taken place.

Nuclear propulsion enables submarines to remain submerged and escape detection by radar. This, plus its increased speed, makes the nuclear submarine a formidable threat. To combat this, sonar sensors for detection of submarines are now being formed into arrays. This increases the sensitivity and rejects extraneous noise, especially important in regions of turbulence.

The search for more sensitive systems of detection will go on. Measurement of the temperature change in the water in which a submarine lies and the magnetic anomaly observable when it is under the water are two directions in which study is being pursued. A range of such measurements may become possible. Testing of laser beams for underwater recognition capability has been proceeding for some time. The problem is extremely difficult, water being a medium quite different from air, and much work will be needed to overcome the obstacles.

The subject is closely linked with the study of undersea conditions generally; that is, oceanography. American efforts dwarf those of any other Western nation, though France, a pioneer in undersea exploration, is active. Underwater acoustic navigation enables ships to be used for missile or satellite tracking. Underwater communication over very long distances is essential for the control of nuclear submarines, to make the most of their almost unlimited radius of operation.

(margin note: Underwater laser beams)

WARNING SYSTEMS

Modern systems. *Air defense systems.* Radar and identification friend or foe (IFF) equipment constitute the forward elements of complex systems that have appeared throughout the world. Examples include the semiautomatic ground environment (SAGE), augmented by a mobile backup intercept control system called BUIC in the United States, NATO air defense ground environment (NADGE) in Europe, a similar system in Japan, and various land-mobile, airborne, and ship command and control systems. Little information concerning the Soviet systems is available, but they are known to be extensive, automated, and capable.

Air-defense systems require computers and communication nets to process the radar data. Position reports from the radars are formed into tracks of each detected aircraft. Height-finding radars add the third dimension. The IFF information, together with known flight plans, is correlated; clutter, false returns from clouds, and any electronic countermeasures are rejected. Decisions are made on whether to counter the attack with interceptors or surface-to-air missiles. The counterattack is controlled by guiding a missile or directing an intercept.

To avoid excessive centralization of equipment that would make the system vulnerable to nuclear attack, the computers and communication facilities are widely dispersed and supplemented by mobile facilities.

In addition to large conventional radars, small distributed radars (called gap fillers) are used to detect low-flying aircraft penetrating gaps in large radar coverage. Over-the-horizon radars and AWACS (airborne warning and control systems) are even more promising. The latter consist of large radar and computation, display, and control systems, housed in large aircraft. First introduced for naval defense, they have become potentially effective over land with new developments in clutter-rejection circuitry.

Large aircraft with powerful radars connected to sophisticated computer and display equipment can survive a nuclear attack and have a low-altitude surveillance capability. Their use, delayed because of problems caused by interference from land clutter, is growing.

A unique air-defense system is the U.S.-Canadian Distant Early Warning system stretching across the northern portion of North America. The radars are used strictly for early warning; no control of missiles or interceptors is provided. Elaborate communications to control centres to the south are part of the system.

(margin note: The DEW line)

Air-defense systems spread the warning to the civil population by sirens and radio alerts. Extensive communication nets are built for this purpose. Air-defense systems also select and assign the defensive weapons to particular threats. If interceptors are used, a control centre is assigned to send control information by digitally encoded radio messages.

If surface-to-air missiles are used, the target is designated to the missile control system, which has its own target-tracking and missile-control radar. Practically all surface-to-air missile systems have some autonomous capability of warning and target acquisition. Examples of these systems are the American Nike Hercules and Hawk, the British Thunderbird, Bloodhound, and Rapier, the French-German Roland, and the Italian Indigo. In sea warfare, such missiles as the U.S. Terrier and Talos, the British Sea Dart, and the French Masurca have autonomous radar capability.

At sea, air defense also uses large radars on ships, but more use is made of airborne radar and control systems. The weight and size of long-range radars restricts their installation to the larger ships; airborne radar over the ocean does not have severe land clutter to contend with, making it simpler than overland systems; the horizon limits are at a greater range; and the aircraft can patrol a large area. As in land defenses, extensive computer and display complexes, and communications between the ships, are used. In the U.S. Navy the Airborne Tactical Data System, consisting of airborne radar, computers, and memory and data links, is connected with the Naval Tactical Data System, located in fleet headquarters, which processes, organizes, and displays information of the overall picture of the tactical situation.

Ballistic missile warning. In the second half of the 20th century, warning against ballistic missiles with nuclear warheads has taken precedence over all other warning systems. Large ground radars, operating in the very high frequency (VHF) or ultrahigh frequency (UHF) range, are used. The radars search the skies and track detected objects. Computers calculate trajectory to determine if the target is a missile or an Earth-orbiting object. Depending on the trajectory, the number of objects, and other criteria, alerts, tentative warnings, or all-out warning signals are transmitted to command centres.

Surface-based radars have one serious flaw: they can detect an object only after it appears above the Earth's horizon. For earlier warning, over-the-horizon radars or satellite-borne infrared detectors can be used.

There are two types of over-the-horizon radars, operating in the high frequency range, which can reflect from the ionosphere. One system, called forward scatter, transmits from one location and receives the signal several thousand miles away on the other side of the launch point. The back-scatter system receives the signal from the same location as the transmitter, as is done in conventional radar. Both systems detect variations in the received signal due to fluctuations in the ionosphere caused by the missile's exhaust plume as it traverses the ionosphere.

Ballistic missile defense. Ballistic missile defense systems have their own warning and acquisition radar systems. These large radars are more sophisticated than the warning radars because they must form accurate tracks for the engagement radars. Decoy objects and lightweight metallic reflectors called chaff must be identified and rejected. To do this, the radars must be able to measure the velocity of all the objects, because lightweight objects decelerate more rapidly than heavy objects due to atmospheric drag and friction.

Space surveillance. Closely allied to warning systems are space-object detection and tracking systems. It is likely that only the United States and the Soviets have developed and operate these systems. A variety of very large radars are used, although the newer installations are phased-array radars that have stationary antennas with electronically steerable multiple beams. The scanning is more rapid than that by a mechanically rotated antenna, and

several objects can be tracked simultaneously. The radars used for ballistic missile early warning are connected into spacetrack nets.

Tracking by telescope

To supplement radars, telescopes have been designed for accurate tracking of comparatively low earth satellites. Telescopes, which can have cameras, have been adapted with varying degrees of success to pick up high-altitude satellites and extremely faint objects. The range depends on the size of the target, its reflectivity, and the solar aspect angle (angular position of the sun in the sky). Telescopes are not detection devices, but they can track objects if they are pointed in the correct direction by the ground radar net.

Detection of nuclear explosions. In 1963 a treaty banning nuclear weapon tests in the atmosphere, in outer space, and underwater was signed. Each signatory nation was to provide monitoring. A direct consequence was the development and construction of a wide variety of devices to monitor nuclear explosions.

Underground explosions, still permitted under the treaty, are monitored by seismometers, instruments that measure minute ground motions. Because of the high sensitivity required to measure at great distances the ground vibrations caused by nuclear explosions, the seismometers record many extraneous motions from natural sources; these are called noise. To reduce noise, a large number of seismometers arranged in arrays is used to reinforce the desired signal and exclude unwanted signals. Elaborate data processing, with the help of recorders and computers, further refines the output. Despite these measures, there is a limit to the sensitivity of underground and underwater systems, so that very small nuclear explosions at great distance from the receiving sites may not be detected or may be wrongly identified as a small earthquake.

Sensing an explosion in space

Detection of explosions in the atmosphere and in space depends upon measuring the products of an explosion. Acoustic sensors are used to measure the sound waves created by the blast, aircraft and rockets to collect possibly radioactive debris samples, flash detectors to detect the light flash as well as the radio pulse generated by the explosion, and a number of radio-detection techniques to measure the considerable disturbance of the ionosphere. None of the techniques is adequate by itself, since each is disturbed by various background signals. Analyzed together, however, they yield positive results.

To detect explosions in space, high-altitude satellites are used. They carry detectors of X-ray emissions, gamma rays, and neutrons, all of which are generated by a nuclear explosion. They can be detected because there is essentially no atmosphere in space to absorb the emissions.

Infiltration and base defense systems. The growth of insurgency warfare has made necessary the development of a variety of sensors to detect vehicles and personnel in the jungle along trails or on roads. Acoustic, seismic, magnetic, infrared, radar, and Doppler radar (radars that detect movement by shift in frequency of received signal) are the sensors.

The sensors are connected to processing centres where the progress of an infiltrating column or truck convoy can be monitored. This process eliminates many false detections due to random noise or animals. Because the sensors are widespread and the processing quite sophisticated, the systems have become known as the instrumented battlefield or electronic barrier.

Aerial reconnaissance. Aerial reconnaissance has grown in importance; it now encompasses all phases of warning. Visual observation from the air furnishes short-term information and warning. Direct receiving and image-recording infrared equipment in night reconnaissance, high resolution radar in bad weather, and conventional photography all contribute to medium and long-term warning by observing tactical preparations or discerning new military capabilities.

Manned aircraft are used more frequently than other platforms for these sensors. Unmanned aircraft, however, flying at low and high altitudes; helicopters, including small unmanned helicopters; and space vehicles are all used for various reconnaissance missions.

Photography from rockets was first undertaken in 1906.

A model for military reconnaissance was built in 1912, but by this time photography from airplanes had been shown to be feasible. After the launching of the first Soviet satellite, Sputnik 1, in 1957, the potential of observations from space vehicles became obvious and various applications were developed.

Detection from a satellite

Satellite platforms can carry a variety of sensors. Cameras in space can collect images on photographic film, infrared images, or television-type signals. Radars can be carried aloft for operation at night or through clouds that could otherwise obscure the images. Infrared sensors can be used to detect missiles, or space warnings. Sensors to detect nuclear explosions can also be used to monitor possible violations of the nuclear test treaty.

To be useful, the sensors must have high resolution. The large distances involved make this difficult. Cameras must have telescopic optics and must be quite large and heavy. As the ability to lift larger weights to orbital altitudes increases, the capabilities of the sensors will improve. Infrared sensors also need heavy equipment. Radar sensors are limited not only in resolution (generally much poorer than optical sensors) but by electrical power limitations, since quite powerful radar transmitters are necessary.

Photographic resolution of about one second of arc is achievable today. At 200 miles (320 kilometres) altitude, this would be equivalent to a resolution of 10 feet (three metres); that is, an object 10 feet in diameter could be clearly distinguished. Vibration and high speed reduce this resolution considerably.

Antisubmarine systems. The limited range of both active (echo-ranging) and passive (listening) sonar makes the use of many sensors necessary in submarine detection. To guard a shore, a line of sensors can be set on the ocean floor. In the broad ocean area, however, the sensors on ships and submarines leave vast spaces uncovered. To fill these gaps, sonobuoys, floating buoys with sonar sensors and radio transmitters, are used. The signals from the sonobuoys are received by patrolling aircraft; these then track the submarines.

Naval vessels use helicopters for submarine detection and warning. Each carries a sonar sensor at the end of a cable, lowering it into the water to detect submarines. Such sensors are called dunked sonar sensors.   (Ha.D.)

Military communication

Military communication, or signaling, has long played an important role in warfare. It provides the means for transmitting information from reconnaissance and other units in contact with the enemy and the means for exercising command by transmitting the orders and instructions of commanders to their subordinates. It comprises all means of transmitting messages, orders, and reports, both in the field and at sea and between headquarters and distant installations or ships.

EARLY DEVELOPMENT

Messengers have been employed in war since ancient times and still constitute a valuable means of communication. Alexander, Hannibal, and Caesar each developed an elaborate system of relays by which messages were carried from one messenger post to another by mounted messengers traveling at top speed. They were thus able to maintain contact with their homelands during their far-flung campaigns and to transmit messages with surprising speed. Genghis Khan at the close of the 12th century not only emulated his military predecessors by establishing an extensive system of messenger posts from Europe to his Mongol capital but also utilized homing pigeons as messengers. As he advanced upon his conquests he established pigeon relay posts across Asia and much of eastern Europe. He was thus able to use these messengers to transmit instructions to his capital for the governing of his distant dominions. Before the end of the 18th century European armies used the visual telegraph system devised by Claude Chappe, employing semaphore towers or poles with movable arms. The Prussian army in 1833 assigned such visual telegraph duties to engineer troops.

Genghis Khan's homing pigeons

At the same time that these elementary methods of signal

communication were being evolved on land, a comparable development was going on at sea. Early signaling between naval vessels was by prearranged messages transmitted by flags, lights, or the movement of a sail. Codes were developed in the 16th century that were based upon the number and position of signal flags or lights or on the number of cannon shots. In the 17th century the British admiral Sir William Penn and others developed regular codes for naval communication; and toward the close of the 18th century, Admiral Richard Kempenfelt developed a plan of flag signaling similar to that now in use. Later Sir Home Popham increased the effectiveness of ship-to-ship communication by improved methods of flag signaling.

THE ADVENT OF ELECTRICAL SIGNALING

Despite the early pioneering efforts on land and sea the real development of signal communication in war did not come until after invention of the electric telegraph by Samuel F.B. Morse. In his successful demonstration of electric communication between Washington, D.C., and Baltimore in 1844, he provided a completely new means of rapid signal communication. The development of the Morse Code of dots and dashes used with key and sounder was soon used to augment the various means of visual signaling. Vice Admiral Philip Colomb's flash signaling, adopted in the British navy in 1867, was an adaptation of the Morse code to lights. The first application of the telegraph in time of war was made by the British in the Crimean War in 1854, but its capabilities were not well understood, and it was not widely used. Three years later, in the Indian Mutiny, the newly established telegraph, which was controlled by the British, was a deciding factor.

Telegraph
in the
American
Civil War

In the American Civil War (1861–65), wide use was made of the electric telegraph. In addition to its employment in spanning long distances under the civilian-manned military telegraph organization, mobile field service was provided in the Union army by wagon trains equipped with insulated wire and lightweight poles for the rapid laying of telegraph lines. Immediately before and during the Civil War visual signaling also received added impetus through development of a system, applying the Morse code of dots and dashes, that spelled out messages with flags by day and lights or torches by night. Another development for light signaling placed a movable shutter, controlled by a key, in front of a strong light. An operator, opening and closing the shutter, could produce short and long flashes to spell out messages in Morse code.

Simultaneously, the Prussian and French armies also organized mobile telegraph trains. During the short, decisive Prussian campaign against Austria in 1866, field telegraph enabled Count Helmuth von Moltke, the Prussian commander, to exercise command over his distant armies. Soon afterward the British organized their first field telegraph trains in the Royal Engineers.

Another instrument was added to the techniques for visual signaling through the development of the heliograph. It employed two adjustable mirrors so arranged that a beam of light from the sun could be reflected in any direction. The beam was interrupted by a key-operated shutter that permitted the formation of the dots and dashes of the Morse code. Where climatic conditions were favourable this instrument found much use, notably by the British army in India and the U.S. Army in the American Southwest. Because consistency and regularity of sunshine were important, the heliograph was never widely adopted throughout the armies of continental Europe.

The invention of the telephone in 1876 was not followed immediately by its adoption and adaptation for military use. This was probably due to the fact that the compelling stimulation of war was not present and to the fact that the development of long-distance telephone communication was not achieved for many years. The telephone was used by the U.S. Army in the Spanish-American War, by the British in the South African (Boer) War, and by the Japanese in the Russo-Japanese War. This military use was not extensive, and it made little material contribution to the development of voice telephony. Before the outbreak of World War I, military adaptation of the telephone did take place, but its period of growth had not yet arrived.

Near the close of the 19th century, a new means of military signal communication made its appearance—the wireless telegraph, or radio. The major powers throughout the world were quick to see the wonderful possibilities for military and naval signaling. Development was rapid and continuous, and, by 1914, it was adopted and in extensive use by all the armies and navies of the world. It soon became apparent that wireless telegraphy was not an unmixed blessing to armies and navies, because it lacked secrecy and messages could be heard by the enemy as well as by friendly forces. This led to the development of extensive and complicated codes and ciphers as necessary adjuncts to military signaling. The struggle between the cryptographer and the cryptanalyst expanded greatly with the adoption of radio and continued to be a major factor affecting its military use.

FROM WORLD WAR I TO 1940

The onset of World War I found the opposing armies equipped to a varying degree with modern means of signal communication but with little appreciation of the enormous load that signal systems must carry to maintain control of the huge forces that were set in motion. The organization and efficiency of the armies varied greatly. At one end of the scale was Great Britain, with a small but highly developed signal service; and at the other end stood Russia, with a signal service inferior to that of the Union Army at the close of the American Civil War. The fact that commanders could not control, coordinate, and direct huge modern armies without efficient signal communication quickly became apparent to both the Allies and the Central Powers. The Germans, despite years of concentration on the Schlieffen Plan, failed to provide adequately for communication between higher headquarters and the rapidly marching armies of the right wing driving through Belgium and northern France. This resulted in a lack of coordination between these armies, which caused a miscarriage of the plan, a forced halt in the German advance, and the subsequent withdrawal north of the Marne. On the Allied side, the debacle of the Russian forces in East Prussia—a crushing defeat at the hands of General Paul von Hindenburg in the Battle of Tannenberg—was largely due to an almost total lack of signal communication.

As the war progressed there was a growing appreciation of the need for improved electrical communications of much greater capacity for the larger units and of the need within regiments for electrical communications, which had heretofore been regarded as unessential and impractical. Field telephones and switchboards were soon developed, and those already in existence were improved. An intricate system of telephone lines involving thousands of miles of wire soon appeared on each side. Pole lines with many crossarms and circuits came into being in the rear of the opposing armies, and buried cables and wires were laid in the elaborate trench systems leading to the forwardmost outposts. The main arteries running from the rear to the forward trenches were crossed by lateral cable routes roughly parallel to the front.

The
telephone
in
World
War I

Thus, there grew an immense gridwork of deep buried cables, particularly on the German side and in the British sectors of the Allied side, with underground junction boxes and test points every few hundred yards. The French used deep buried cable to some extent but generally preferred to string their telephone lines on wooden supports set against the walls of deep open trenches. Thus electrical communication in the form of the telephone and telegraph gradually extended to the smaller units until frontline platoons were frequently kept in touch with their company headquarters through these mediums.

Despite efforts to protect the wire lines, they were frequently cut at critical times as the result of the intense artillery fire. This led all the belligerents to develop and use radio (wireless) as an alternate means of communication. Prewar radio sets were too heavy and bulky to be taken into the trenches, and they also required large and highly visible aerials. Radio engineers of the belligerent nations soon developed smaller and more portable sets powered by storage batteries and using low, inconspicuous aerials. Although radio equipment came to be issued to

the headquarters of all units, including battalions, the ease of enemy interception, the requirements for cryptographing or encoding messages, and the inherent unreliability of these early systems caused them to be regarded as strictly auxiliary to the wire system and reserved for emergency use when the wire lines were cut. Visual signaling returned to the battlefield in World War I with the use of electric signal lamps. Pyrotechnics, rockets, Very pistols, and flares had a wide use for transmitting prearranged signals. Messenger service came to be highly developed, and motorcycle, bicycle, and automobile messenger service was employed. Homing pigeons were used extensively as one-way messengers from front to rear and acquitted themselves extremely well. Dogs were also used as messengers and, in the German army, reached a high degree of efficiency.

A new element in warfare, the airplane, introduced in World War I, immediately posed a problem in communication. During most of the war, communication between ground and air was difficult and elementary. To make his reports the pilot had to land or drop messages, and he received instructions while in the air from strips of white and black cloth called "panels" laid out in an open field according to prearranged designs. Extensive efforts were made to use radiotelegraph and radiotelephone between the airplanes and ground headquarters. The closing stages of the war saw many planes equipped with radio, but the service was never satisfactory or reliable and had little influence on military operations.

During World War I, wireless telegraph communication was employed extensively by the navies of the world and had a major influence on the character of naval warfare. High-powered shore and ship stations made wireless communication over long distances possible.

One of the war lessons learned by most of the major nations was the compelling need for scientific research and development of equipment and techniques for military purposes. Although the amount of funds devoted to military development during the period from World War I to World War II was relatively small, the modest expenditures served to establish a bond between industry, science, and the armed forces of the major nations.

Of great importance in postwar radio communication was the pioneering by amateurs and by industry and science in the use of very high frequencies. These developments opened up to the armed services the possibilities of portable short-range equipment for mobile and portable tactical use by armies, navies, and air forces. Military work in these fields was carried out actively in Germany, Great Britain, and the United States. As early as 1938 Germany had completed the design and manufacture of a complete line of portable and mobile radio equipment for its army and air force.

Between World Wars I and II the printing telegraph, commonly known as the teleprinter or teletypewriter machine, came into civilian use and was incorporated in military wire-communication systems, but military networks were not extensive. Before World War II, military radioteleprinter circuits were nonexistent.

Another major communication advance that had its origin and early growth during the period between World Wars I and II was frequency-modulated (FM) radio. Developed during the late 1920s and early 1930s by Edwin H. Armstrong, an inventor and a major in the U.S. Army Signal Corps during World War I, this new method of modulation offered heretofore unattainable reduction of the effect of ignition and other noises encountered in radios used in vehicles. It was first adapted for military use by the U.S. Army, which, prior to World War II, had under development tank, vehicular, and man-pack frequency-modulated radio transmitters and receivers.

On the eve of World War II, all nations employed generally similar methods for military signaling. The messenger systems included foot, mounted, motorcycle, automobile, airplane, homing pigeon, and the messenger dog. Visual agencies included flags, lights, panels for signaling airplanes, and pyrotechnics. The electrical agencies embraced wire systems providing telephone and telegraph service, including the printing telegraph. Both radiotelephony and

(margin: Radio-equipped aircraft)

(margin: FM radio)

radiotelegraphy were in wide use, but radiotelephony had not as yet proved reliable and satisfactory for tactical military communication. The navies of the world entered World War II with highly developed radio communication systems, both telegraph and telephone, and with development under way of many electronic navigational aids. Blinker-light signaling was still used. The use of telephone systems and loud-speaking voice amplifiers on naval vessels had also come into common use. Air forces employed wire and radio communication to link up their bases and landing fields and had developed airborne long-range, medium-range, and short-range radio equipment for air-to-ground and air-to-air communication.

WORLD WAR II AND AFTER

In communications electronics, World War II was in one sense similar to World War I: the most extravagant prewar estimates of military requirements proved to represent only a fraction of the actual demand. The need for all kinds of communication equipment and for improved quality and quantity of communications pyramided beyond the immediate capabilities of industry. An increase in manufacturing plant became vital, and research and development in the communications–electronics field was unprecedented. The early German blitzkrieg, with tank and armoured formations, placed a new order of importance on reliable radio communication.

The development of the air, infantry, artillery, and armoured team created new requirements for split-second communication by radio among all members. Portable radio sets were provided as far down in the military echelons as the platoon. In every tank there was at least one radio and in some command tanks as many as three. Multiconductor cables were provided wire communications; they could be reeled out rapidly and as many as four conversations could take place on them simultaneously through the use of carrier telephony. The Germans were the first to use this type of military long-range cable, and their example was followed promptly by both the British and the U.S. forces. High-powered mobile radio sets became common at division and regimental level. With these sets telegraph communication could be conducted at distances of more than 100 miles (160 kilometres) with vehicles in normal motion on the road. Major telephone switchboards of much greater capacity were needed. These were developed, manufactured, and issued for use at all tactical headquarters to satisfy the need for the greatly increased number of telephone channels required to coordinate the movements of field units whose mobility had been expanded many times.

Radio relay, born of the necessity for mobility, became the outstanding communication development of World War II. Sets employing frequency modulation and carrier techniques were developed and used, as were also radio relay sets that used radar pulse transmission and reception techniques and multiplex time-division methods for obtaining many voice channels from one radio carrier. Radio relay telephone and teletypewriter circuits spanned the English Channel for the Normandy landing and later furnished important communication service for General George S. Patton, after his breakout from the Normandy beachhead.

The need for communication between the homelands and many far-flung theatres of war gave rise to the need for improved long-range overseas communication systems. A system of radioteletypewriter relaying was devised, by which a radioteletypewriter operator in Washington, London, or other capitals could transmit directly by teleprinter to the commander in any theatre of war. In addition, a system of torn-tape relay centres was established so that tributaries could forward messages through the major centres and retransmit quickly by transferring a perforated tape message from the receiving to the transmitting positions. In addition a system of holding teletypewriter conferences was developed. These conferences, called "telecons," enabled a commander or his staff at each end to view on a screen the incoming teletypewriter messages as fast as the characters were received. Questions and answers could be passed rapidly back and forth over the thousands of miles

(margin: Mobile communications)

separating the Pentagon in Washington, D.C., for example, from the supreme Allied headquarters in Europe or General Douglas MacArthur's headquarters in the Far East.

During the latter years of the war, new and improved communication and electronic devices came forth from research and development in ever-increasing numbers. A new long-range electronic navigation device, known as loran, used for both naval vessels and aircraft, was developed, as were short-range navigational systems, called shoran. Combinations of radar and communications for the landing of aircraft in zero visibility were perfected. One such system was the GCA, or ground-controlled approach system. Combinations of radio direction-finding, radar, and communications systems were developed and used for ground control of intercept aircraft—the system called GCI (ground-controlled intercept). Radio-controlled guidance of falling bombs enabled an operator in a bomber to direct a bomb to the target. Electronic countermeasures made their appearance in the form of jamming transmitters to jam radio channels and radar, navigation, and other military electronics.

The military services learned well from their wartime experiences the importance of scientific research and development in all fields, including communications electronics. Advances were made in the communication capacity of wire and radio relay systems and in improved electronic aids for navigation. Measures to provide more comprehensive and more reliable communication and electronic equipment continued to be stressed in the armies, navies, and air forces of the major powers.

After mid-century, accordingly, military efforts in all the many facets of signal communication continued to intensify almost as extravagantly as during World War II. Two major additions in the U.S. Army were television and "electronic brain" equipment. The latter, in many forms of digital and analog computers and of such data-processing devices as punch-card machines, were applied increasingly to personnel record handling and to depot and supply operations interconnected over wide areas by signal-communication networks.

Television proved a valuable training aid in military schools, where mass instruction, especially in manual skills, was needed and where instructors were few. A single instructor could teach many small classes simultaneously, each grouped before a TV set where they could watch demonstrations closely. Two-way communication permitted the instructor to call and question any student in any classroom and enabled any student to put questions to the instructor. Portable television equipment in the field proved valuable for sending back to headquarters, by antenna radiation or coaxial cable, a picture of any scene of operations such as a river crossing. Equally valuable was a television camera in the hands of a forward scout or in a reconnaissance aircraft, whether piloted or remotely controlled, to scan enemy territory.

Thus signal communication, combining in itself the powers of photography, television, radar, and other instruments using the electromagnetic radiation spectrum, moved into such new areas of military electronics as battle area surveillance and electronic warfare devices to interfere with, or jam, enemy transmitters. In the U.S. Army, battle area surveillance radically augmented conventional reconnaissance methods. An electronically controlled target acquisition system, to discover enemy troops or transport on the ground or in the air, was being developed using optical, sonic, photographic, infrared, and radar equipment. The aggregate of information gathered by these devices over a wide enemy front can be assembled electronically and displayed at headquarters where the combat commander can quickly estimate the situation and make tactical decisions. (G.I.Bk./G.R.T.)

BIBLIOGRAPHY

Military technology before the modern era. ARTHUR FERRILL, *The Origins of War: From the Stone Age to Alexander the Great* (1985), offers a scholarly survey of evidence for prehistoric war. For a glimpse of the vestiges of prehistoric tradition in modern times, see the article "Ancient World of a War-Torn Tribe: Willigiman-Wallalua People," *Life,* 53(13):73–91 (Sept. 28, 1962), which contains dramatic photographs of New Guinea tribesmen skirmishing with javelins. JAMES D. MUHLY, "How Iron Technology Changed the Ancient World and Gave the Philistines a Military Edge," *The Biblical Archaeology Review,* 8(6):40–54 (November/December 1982), analyzes early metalworking techniques and their role in the beginnings of military technology. YIGAEL YADIN, *The Art of Warfare in Biblical Lands in the Light of Archaeological Study,* 2 vol. (1963; originally published in Hebrew, 1963), applies an operational perspective to the development of military technology and tactics in ancient and early classical time, but some of the author's conclusions need to be modified in light of subsequent archaeological discoveries. P.A.L. GREENHALGH, *Early Greek Warfare: Horsemen and Chariots in the Homeric and Archaic Ages* (1973), offers a revisionist analysis of the use of horses in war. J.G. LANDELS, *Engineering in the Ancient World* (1978), presents a comparative study of human and animal muscle, wind, and falling water as sources of power and has separate chapters on land and sea transport and catapult design. A.M. SNODGRASS, *Arms and Armour of the Greeks* (1967), is a brief but scholarly work on the subject. F.E. ADCOCK, *The Greek and Macedonian Art of War* (1957, reprinted 1967); and E.W. MARSDEN, *Greek and Roman Artillery: Historical Development* (1969), remain standard treatments. WERNER SOEDEL and VERNARD FOLEY, "Ancient Catapults," *Scientific American,* 240(3):150–160 (March 1979), is an illustrated technical analysis. EDWARD N. LUTTWAK, *The Grand Strategy of the Roman Empire From the First Century A.D. to the Third* (1976), devotes considerable attention to technical aspects of Rome's military power. J.F.C. FULLER, *The Generalship of Alexander the Great* (1958, reissued 1981), remains a standard historical treatment of the organization and use of the army; it can be supplemented by the brilliant examination in DONALD W. ENGELS, *Alexander the Great and the Logistics of the Macedonian Army* (1978). Brief historical surveys of equipment and dress, based on artistic interpretations of archaeological evidence, are presented in the works from the "Men-at-Arms" series: TERENCE WISE, *Ancient Armies of the Middle East* (1981), and *Armies of the Carthaginian Wars, 265–146 BC* (1982); NICK SEKUNDA, *The Ancient Greeks: Armies of Classical Greece, 5th and 4th Centuries BC* (1986), and *The Army of Alexander the Great* (1984); and MICHAEL SIMKINS, *The Roman Army From Caesar to Trajan,* rev. ed. (1984).

MICHEL BUR, "The Social Influence of the Motte-and-Bailey Castle," *Scientific American,* 248(5):132–140 (May 1983), describes the early beginnings of the European feudal system of war; and JOHN BEELER, *Warfare in Feudal Europe, 730–1200* (1971), summarizes the subject. BERNARD S. BACHRACH, "Animals and Warfare in Early Medieval Europe," in the symposium *L'Uomo di fronte al mondo animale nell'alto Medioevo,* vol. 1, pp. 707–751 (1985), analyzes textual, graphic, and archaeological evidence on the development of the technology of mounted shock action in western Europe; the same author's *Merovingian Military Organization, 481–751* (1972) examines the social context within which the new technology developed. A.V.B. NORMAN, *The Medieval Soldier* (1971); and A.V.B. NORMAN and DON POTTINGER, *English Weapons & Warfare, 449–1660* (1979, reissued 1985), address weaponry in detail. CHARLES FFOULKES, *Armour & Weapons* (1909, reprinted 1973), remains a classic treatment of the development of personal armour in Europe.

V.J. PARRY and M.E. YAPP (eds.), *War, Technology, and Society in the Middle East* (1975), contains a number of essays dealing with various aspects of warfare and military technology during the age of cavalry. DAVID C. NICOLLE, *Arms and Armour of the Crusading Era, 1050–1350,* 2 vol. (1988), is a comprehensive reference work. FRANK A. KIERMAN, JR., and JOHN K. FAIRBANK (eds.), *Chinese Ways in Warfare* (1974), is a collection of scholarly essays. S.R. TURNBULL, *The Mongols* (1980); and DAVID C. NICOLLE, *The Armies of Islam, 7th–11th Centuries* (1982), are two works from the "Men-at-Arms" series. RALPH PAYNE-GALLWEY, *A Summary of the History, Construction, and Effects in Warfare of the Projectile-Throwing Engines of the Ancients with a Treatise on the Structure, Power, and Management of Turkish and Other Oriental Bows of Mediaeval and Later Times* (1907, reprinted 1973), though old, contains valuable reports of practical experiments in the reconstruction of mechanical artillery and informed speculation on the capabilities of the composite bow. W.F. PATERSON, "The Archers of Islam," *Journal of the Economic and Social History of the Orient,* 9(1–2):69–87 (November 1966), offers technical and tactical analysis of medieval archery. PAUL E. KLOPSTEG, *Turkish Archery and the Composite Bow: A Review of an Old Chapter in the Chronicles of Archery, and a Modern Interpretation,* 3rd enlarged ed. (1987), contains the most complete technical description of composite bow construction, based on an 1847 Ottoman text written during the final revival of Turkish archery. RALPH PAYNE-GALLWEY, *The Crossbow, Mediaeval and Modern, Military and Sporting: Its Construction, History & Management, with a Treatise on the Balista and Catapult*

In the margin:
Electronic detection, navigation, and guidance

of the Ancients, and an Appendix on the Catapult, Balista & the Turkish Bow, 2nd ed. (1958, reprinted 1981), remains the basic text on the crossbow; ROBERT HARDY, *Longbow: A Social and Military History* (1976, reissued 1986), is a definitive treatment by a famous archer, with appendixes on design and ballistics by technical experts. The above-mentioned "Men-at-Arms" series includes DOUGLAS MILLER, *The Landsknechts* (1976) and *The Swiss at War, 1300–1500* (1979); DAVID C. NICOLLE, *Armies of the Ottoman Turks, 1300–1774* (1983); and S.R. TURNBULL, *Samurai Armies, 1550–1615* (1979). Though not primarily concerned with warfare or military technology, NORMAN ITZKOWITZ, *Ottoman Empire and Islamic Tradition* (1972, reprinted 1980); and PETER DUUS, *Feudalism in Japan,* 2nd ed. (1976), provide the institutional and cultural context for military developments.

DAVID AYALON, *Gunpowder and Firearms in the Mamluk Kingdom: A Challenge to a Mediaeval Society,* 2nd ed. (1978), studies a military elite that failed to adapt to gunpowder. CHARLES OMAN, *A History of the Art of War in the Middle Ages,* 2nd rev. ed., 2 vol. (1924, reissued 1959), and *A History of the Art of War in the Sixteenth Century* (1937, reprinted 1979), provide encyclopaedic coverage and analytical treatment. F.L. TAYLOR, *The Art of War in Italy, 1494–1529* (1921, reprinted 1973), is a useful supplement. JACOB DE GHEYN, *The Exercise of Armes: A Seventeenth Century Military Manual,* new ed., edited by DAVID J. BLACKMORE (1986; originally published in Dutch, 1607), is one of the earliest published detailed books of musket drill. PHILIP J. HAYTHORNTHWAITE, *Weapons and Equipment of the Napoleonic Wars* (1979), provides comprehensive coverage of the subject. KENNETH MACKSEY, *The Guinness History of Land Warfare* (1973; also published as *The History of Land Warfare,* 1974), is a useful reference source. CHRISTOPHER DUFFY, *The Military Experience in the Age of Reason* (1987), is a comprehensive treatment of European methods of war. GEOFFREY PARKER, *The Army of Flanders and the Spanish Road, 1567–1659: The Logistics of Spanish Victory and Defeat in the Low Countries' Wars* (1972), examines human and tactical aspects of the war of the Netherlands, and his *The Military Revolution: Military Innovation and the Rise of the West, 1500–1800* (1988), uses current scholarship in an analysis of the impact of gunpowder on warfare and politics on a global scale.

CHRISTOPHER DUFFY, *Fire and Stone: The Science of Fortress Warfare, 1660–1860* (1975), and *Siege Warfare,* vol. 1: *The Fortress in the Early Modern World, 1494–1660,* and vol. 2: *The Fortress in the Age of Vauban and Frederick the Great, 1680–1789* (1979–85), treat the development of methods of siege craft and fortification and survey positional warfare. SÉBASTIEN LE PRESTRE DE VAUBAN, *A Manual of Siegecraft and Fortification,* trans. and ed. by GEORGE A. ROTHROCK (1968; originally published in French, 1740), is the famous text with informative notes, appendixes, and introduction; and SIMON PEPPER and NICHOLAS ADAMS, *Firearms & Fortification: Military Architecture and Siege Warfare in Sixteenth-Century Siena* (1986), studies the technology and tactics of early modern positional warfare in detail. PETER YOUNG and WILFRID EMBERTON, *Sieges of the Great Civil War, 1642–1646* (1978), offers siege narratives of the English Civil War; and HORST DE LA CROIX, *Military Considerations in City Planning: Fortifications* (1972), surveys urban fortifications from the earliest times to the mid-19th century.

For the transition to modern warfare, see WILLIAM H. MCNEILL, *The Pursuit of Power: Technology, Armed Force, and Society Since A.D.1000* (1982), a broad overview of the political and economic effect of developments in military technology; HEW STRACHAN, *European Armies and the Conduct of War* (1983), which summarizes developments from the age of Frederick the Great onward; and MARTIN VAN CREVELD, *Technology and War: From 2000 B.C. to the Present* (1989). (J.F.G.)

Modern weapons and weapon systems: On small arms, basic reference works offering encyclopaedic treatment include CLAUDE BLAIR (ed.). *Pollard's History of Firearms* (1983); JAROSLAV LUGS, *Firearms Past and Present: A Complete Review of Firearms Systems and Their Histories,* 2 vol., trans. from Czech (1973); and HAROLD L. PETERSON (ed.), *Encyclopedia of Firearms* (1964). Histories of small-arms development in various countries include HOWARD L. BLACKMORE, *British Military Firearms, 1650–1850* (1961); M.L. BROWN, *Firearms in Colonial America: The Impact on History and Technology, 1492–1792* (1980); JOHN WALTER, *The German Rifle: A Comprehensive Illustrated History of the Standard Bolt-Action Designs, 1871–1945* (1979); and EDWARD C. EZELL, *The AK-47 Story: Evolution of the Kalashnikov Weapons* (1986), including a history of shoulder-weapons development in Russia and the Soviet Union from 1800 to the 1980s, and *The Great Rifle Controversy: Search for the Ultimate Infantry Weapon from World War II Through Vietnam and Beyond* (1984), on U.S. and NATO small-arms development. Other works by Ezell are

Handguns of the World: Military Revolvers and Self-Loaders from 1870 to 1945 (1979); and *Small Arms of the World: A Basic Manual of Small Arms,* 12th rev. ed. (1983), with chapters that summarize the development of rifles, handguns, submachine guns, machine guns, and special-purpose weapons from 1945 to the 1980s. MERRITT ROE SMITH, *Harpers Ferry Armory and the New Technology: The Challenge of Change* (1977), discusses the American system of manufacture in its human and technological contexts. JOHN ELLIS, *The Social History of the Machine Gun* (1975, reprinted 1986), is an essay on the social impact of the machine gun. (E.C.E.)

On artillery, a full history of gun design and development in the second half of the 19th century is presented in the official British handbook *Treatise on Service Ordnance,* 7th ed. (1908); an overview of artillery knowledge of that period, with useful historical background, is offered in E.W. LLOYD and A.G. HADCOCK, *Artillery: Its Progress and Present Position* (1893). The design and development of the guns, carriages, ammunition, and tactics, with descriptions of current weapons, are covered in H.A. BETHELL, *Modern Guns and Gunnery, 1910: A Practical Manual for Officers of the Horse, Field, and Mountain Artillery,* new ed. (1910), and *Modern Artillery in the Field: A Description of the Artillery of the Field Army, and the Principles and Methods of Its Employment* (1911). THOMAS J. HAYES, *Elements of Ordnance: A Textbook for Use of Cadets of the United States Military Academy* (1938), is a later textbook covering the design and construction of guns, mountings, ammunition, and fire-control equipment in ample detail. IAN V. HOGG, *A History of Artillery* (1974), is a profusely illustrated history providing considerable technical detail on the development of arms from the 12th century to the present day. *Jane's Armour and Artillery* (annual) lists all current tanks and artillery weapons, with descriptions, specifications, and illustrations. (I.V.H.)

On missile systems, see KENNETH W. GATLAND, *Development of the Guided Missile,* 2nd ed. (1954), a somewhat technical examination of early efforts. Other historical works include HOMER E. NEWELL, *Guide to Rockets, Missiles, and Satellites,* 2nd rev. ed. (1961); ERIC BURGESS, *Long-Range Ballistic Missiles* (1961); E. MICHAEL DEL PAPA, *From SNARK to SRAM: A Pictorial History of Strategic Air Command Missiles* (1976); NORMAN POLMAR, *Strategic Weapons: An Introduction,* rev. ed. (1982); and KENNETH P. WERRELL, *The Evolution of the Cruise Missile* (1985). Characteristics of strategic weapons are covered in MICHAEL J.H. TAYLOR, *Missiles of the World,* 3rd ed. (1980); and PHILIP BIRTLES and PAUL BEAVER, *Missile Systems* (1985). Some insight into future developments is suggested in MAX WALMER, *An Illustrated Guide to Strategic Weapons* (1988); and UNITED STATES. DEPARTMENT OF DEFENSE, *Soviet Military Power: An Assessment of the Threat, 1988* (1988). The latest developments in the field are covered in *Jane's Weapon Systems* (annual) and *The International Countermeasures Handbook* (annual). (S.O.F./J.F.G.)

The history of nuclear weapons is the subject of voluminous literature. RICHARD RHODES, *The Making of the Atomic Bomb* (1986), is an excellent work on the U.S. effort to develop nuclear weapons. It can be supplemented by the official histories: VINCENT C. JONES, *Manhattan, the Army and the Atomic Bomb* (1985); DAVID HAWKINS, EDITH C. TRUSLOW, and RALPH CARLISLE SMITH, *Manhattan District History-Project Y, the Los Alamos Project,* 2 vol. (1961, reprinted as *Project Y, the Los Alamos Story,* in 1 vol. with a new introduction, 1983); and RICHARD G. HEWLETT, OSCAR E. ANDERSON, JR., and FRANCIS DUNCAN, *A History of the United States Atomic Energy Commission,* 2 vol. (1962–69); continued by RICHARD G. HEWLETT and JACK M. HALL, *Atoms for Peace and War, 1953–1961* (1989). For the development of thermonuclear weapons, see HERBERT F. YORK, *The Advisors: Oppenheimer, Teller, and the Superbomb* (1976); and HANS A. BETHE, "Comments on the History of the H-Bomb," *Los Alamos Science,* 3(3):43–53 (Fall 1982). Technical data are compiled in THOMAS B. COCHRAN, WILLIAM M. ARKIN, and MILTON H. HOENIG, *U.S. Nuclear Forces and Capabilities* (1984); and THOMAS B. COCHRAN et al., *U.S. Nuclear Warhead Production* (1987), and *U.S. Nuclear Warhead Facility Profiles* (1987).

The British project is discussed in the official histories of the U.K. Atomic Energy Authority: MARGARET GOWING, *Britain and Atomic Energy, 1939–1945* (1964), and *Independence and Deterrence: Britain and Atomic Energy, 1945–1952,* 2 vol. (1974). Little has been published about the program of the former U.S.S.R., but see DAVID HOLLOWAY, *The Soviet Union and the Arms Race,* 2nd ed. (1984); and THOMAS B. COCHRAN, *Soviet Nuclear Weapons* (1989). No official history is available for the French project. BERTRAND GOLDSCHMIDT, *Les Rivalités atomiques, 1939–1966* (1967), is a semiofficial account by a participant. The Chinese project is covered in JOHN WILSON LEWIS and XUE LITAI, *China Builds the Bomb* (1988). DAVID IRVING, *The German Atomic Bomb* (1968, reprinted 1983), covers the German program; and ROBERT K. WILCOX, *Japan's*

Secret War (1985), examines Japanese work on the atomic bomb. Proliferation developments are followed in LEONARD S. SPECTOR. *Nuclear Proliferation Today* (1984), *The New Nuclear Nations* (1985). *Going Nuclear* (1987), and *The Undeclared Bomb* (1988).   (T.B.C./R.S.N.)

Chemical and biological weapons are the subject of FREDER-ICK J. BROWN, *Chemical Warfare: A Study in Restraints* (1968, reprinted 1981); L.F. HABER, *The Poisonous Cloud: Chemical Warfare in the First World War* (1986); UNITED NATIONS, *Chemical and Bacteriological (Biological) Weapons and the Effects of Their Possible Use: Report of the Secretary General* (1969); WORLD HEALTH ORGANIZATION, *Health Aspects of Chemical and Biological Weapons* (1970); STOCKHOLM INTERNATIONAL PEACE RESEARCH INSTITUTE, *The Problem of Chemical and Biological Warfare: A Study of the Historical, Technical, Military, Legal, and Political Aspects of CBW, and Possible Disarmament Measures,* 6 vol. (1971–75); and MATTHEW MESELSON and JULIAN PERRY ROBINSON, "Chemical Warfare and Chemical Disarmament," *Scientific American,* 242(4):38–47 (April 1980).

(Ma.Me./J.P.P.R.)

Tanks and armoured vehicles are discussed in RICHARD M. OGORKIEWICZ, *Armour: A History of Mechanized Forces* (1960, reissued as *Armoured Forces: A History of Armoured Forces and Their Vehicles,* 1970); and *Design and Development of Fighting Vehicles* (1968), on the technical aspects. The history of various types of vehicles from World War I to the end of World War II is presented in DUNCAN CROW (ed.), *AFVs of World War One* (1970), *British AFVs, 1919–40* (1970), *British and Commonwealth AFVs, 1940–46* (1971), *American AFVs of World War II* (1972), and *Armored Fighting Vehicles of Germany: World War II* (1973). PETER CHAMBERLAIN and HILARY L. DOYLE, *Encyclopedia of German Tanks of World War Two: A Complete Illustrated Directory of German Battle Tanks, Armoured Cars, Self-Propelled Guns, and Semi-tracked Vehicles, 1933–1945* (1978), provides a comprehensive pictorial record. DUNCAN CROW (ed.), *Modern Battle Tanks* (1978). focuses on the period between 1950 and 1970. For particular types of tanks, see WALTER J. SPIELBERGER, *From Half-Track to Leopard 2: The Complete Illustrated History of the Krauss-Maffei Ordnance Department* (1979; originally published in German, 1979); JOHN MILSOM, *Russian Tanks, 1900–1970: The Complete Illustrated History of Soviet Armoured Theory and Design* (1970); and R.P. HUNNICUT, *Sherman: A History of the American Medium Tank* (1978), *Patton: A History of the American Main Battle Tank* (1984), and *Firepower: A History of the American Heavy Tank* (1988). For current information on developments in technology, see *Jane's Armour and Artillery* (annual) and *Jane's Armoured Fighting Vehicle Systems* (annual).   (R.M.O.)

Naval ships and craft are the subject of voluminous literature. For early history, WILLIAM LEDYARD RODGERS, *Naval Warfare Under Oars, 4th to 16th Centuries* (1939, reprinted 1967), and *Greek and Roman Naval Warfare* (1937, reprinted 1973), are older but still the most comprehensive sources on the classical era. J.S. MORRISON and J.F. COATES, *The Athenian Trireme: The History and Reconstruction of an Ancient Greek Warship* (1986), treats in detail design evolution and technological developments. JOHN H. PRYOR, *Geography, Technology, and War: Studies in the Maritime History of the Mediterranean, 649–1571* (1988), explores both military and commercial navigation in the region. JOHN FRANCIS GUILMARTIN, JR., *Gunpowder and Galleys: Changing Technology and Mediterranean Warfare at Sea in the Sixteenth Century* (1974), examines the way in which gunpowder changed the nature of warfare on land as well as at sea. PHILIP COWBURN, *The Warship in History* (1965); RICHARD HOUGH, *Fighting Ships* (1969); and DONALD MACINTYRE and BASIL W. BATHE, *The Man-of-War: A History of the Combat Vessel,* rev. ed. (1974), discuss and illustrate the general evolution of the warship from early to modern times.   (J.F.G.)

The modern era is covered in PETER HODGES, *The Big Gun: Battleship Main Armament, 1860–1945* (1981); NORMAN FRIEDMAN, *Battleship Design and Development, 1905–1945* (1978), and *Modern Warship: Design and Development* (1979); and DAVID R. FRIEDEN (ed.), *Principles of Naval Weapons Systems* (1985). Historical characteristics of the major navies of the world are found in ROGER CHESNEAU and EUGENE M. KOLESNIK (eds.), *Conway's All the World's Fighting Ships, 1860–1905* (1979); ROBERT GARDINER and RANDAL GRAY (eds.), *Conway's All the World's Fighting Ships, 1906–1921* (1985); ROGER CHESNEAU (ed.), *Conway's All the World's Fighting Ships, 1922–1946* (1980); and ROBERT GARDINER (ed.), *Conway's All the World's Fighting Ships, 1947–1982,* 2 vol. (1983). For characteristics by country, see: (*United States*): NORMAN POLMAR, *Ships and Aircraft of the U.S. Fleet,* 14th ed. (1987); NORMAN FRIEDMAN, *U.S. Battleships* (1985), and *U.S. Cruisers* (1984); and PAUL H. SILVERSTONE, *U.S. Warships Since 1945* (1987); (*Great Britain*): . D.K. BROWN, *A Century of Naval Construction: The History of the Royal Corps of Naval Constructors, 1883–1983* (1983); and ALAN RAVEN and JOHN ROBERTS, *British Cruisers of World War Two* (1980), and *British Battleships of World War Two* (1976).

(*Other countries*): JOHN JORDAN, *Soviet Warships: The Soviet Surface Fleet, 1960 to the Present* (1983); NORMAN POLMAR, *Guide to the Soviet Navy,* 4th ed. (1986); HENRI LE MASSON, *The French Navy,* 2 vol. (1969); HANSGEORG JENTSCHURA, DIETER YUNG, and PETER MICKEL, *Warships of the Imperial Japanese Navy, 1869–1945* (1977; originally published in German, 1970); and ERICH GRÖNER (ed.), *Die deutschen Kriegsschiffe, 1815–1945* (1982–   ), with six out of a projected seven volumes published by 1988.

The engineering characteristics of submarines are explored in ULRICH GABLER, *Submarine Design* (1986; originally published in German, 1964); NORMAN FRIEDMAN, *Submarine Design and Development* (1984); EBERHARD RÖSSLER, *The U-Boat: The Evolution and Technical History of German Submarines* (1981; originally published in German, 1975); and JOHN D. ALDEN, *The Fleet Submarine in the U.S. Navy: A Design and Construction History* (1979). ERMINIO BAGNASCO, *Submarines of World War Two* (1977; originally published in Italian, 1973); DORR CARPENTER and NORMAN POLMAR, *Submarines of the Imperial Japanese Navy* (1986); and RICHARD COMPTON-HALL, *The Underwater War, 1939–1945* (1982), discuss underwater naval operations during this specific period. Antisubmarine warfare is the subject of RICHARD COMPTON-HALL, *Submarine Versus Submarine: The Tactics and Technology of Underwater Warfare* (1988).

On aircraft carriers, see DAVID BROWN, *Aircraft Carriers* (1977); ROGER CHESNEAU, *Aircraft Carriers of the World, 1914 to the Present: An Illustrated Encyclopedia* (1984); NORMAN FRIEDMAN, *Carrier Air Power* (1981), *U.S. Aircraft Carriers: An Illustrated Design History* (1983), and *British Carrier Aviation: The Evolution of the Ships and Their Aircraft* (1988).   (N.F.)

For military aircraft, historical overviews are offered by JOHN W.R. TAYLOR (ed.), *The Lore of Flight* (1970, reissued 1986), a technically informed and well-illustrated work with separate sections on history, structures, engines, equipment, and flying, and containing an encyclopaedic index; and DAVID BROWN, CHRISTOPHER SHORES, and KENNETH MACKSEY, *The Guinness History of Air Warfare* (1976), a concise compilation of salient events and developments. Aircraft design is covered in JOHN D. ANDERSON, JR., *Introduction to Flight,* 3rd ed. (1989), an engineering overview of aircraft design and performance at a basic level, incorporating a technically accurate history of manned flight; and EDWARD H. HEINEMANN, ROSARIO RAUSA, and K.E. VAN EVERY, *Aircraft Design* (1985), a study of contemporary theory and practice. Aircraft propulsion is covered in HERSCHEL SMITH, *Aircraft Piston Engines* (1981), a technically informed history of power plants from the Wright era to the years immediately after World War II; and EDWARD W. CONSTANT II, *The Origins of the Turbojet Revolution* (1980), a scholarly history of the development of turbojet engines. For early military aircraft, see RICHARD P. HALLION, *Rise of the Fighter Aircraft, 1914–18* (1984), a technologically and tactically informed account; and JOHN H. MORROW, JR., *German Air Power in World War I* (1982), an account stressing interactions between strategy and tactics on the one hand and social and economic factors on the other. ERIC M. BROWN, *Duels in the Sky: World War II Naval Aircraft in Combat* (1988), is an analysis of combat capabilities, based on personal experience, by a military test pilot. ROBERT L. SHAW, *Fighter Combat,* 2nd ed. (1988), focuses on modern jet aircraft but incorporates a solid historical base. R.A. MASON and JOHN W.R. TAYLOR, *Aircraft, Strategy, and Operations of the Soviet Air Force* (1986), covers the development of military aeronautics in the former Soviet Union. For treatments of radar-evading aircraft, see DOUG RICHARDSON, *Stealth Warplanes* (1989; also published as *Stealth*), a review of the origins of stealth technology with informed speculation on current and future developments.   (J.F.G.)

Airborne warning and control systems are discussed in ARNOLD LEE TESSMER, *Politics of Compromise: NATO and AWACS* (1988); and MIKE HIRST, *Airborne Early Warning: Design, Development, and Operations* (1983). DANIEL FORD, *The Button: The Pentagon's Strategic Command and Control System* (1985); UNITED STATES, CONGRESS, COMMITTEE ON GOVERNMENT OPERATIONS, *Our Nation's Nuclear Warning System: Will It Work If We Need It?* (1986); and STEPHEN KIRBY and GORDON ROBSON (eds.), *The Militarisation of Space* (1987), study missile-attack warning systems. Use of electronics in military engineering is the subject of CHARLES M. DAVIS *et al., Fiberoptic Sensor Technology Handbook* (1982); and RICHARD G. WILEY, *Electronic Intelligence, the Interception of Radar Signals* (1985).

For information on military communications, see R.J. HOLBECHE (ed.), *Land Mobile Radio Systems* (1985); WILLIAM C.Y. LEE, *Mobile Communications Design Fundamentals* (1986); H. HODARA (ed.), *Optical Fibres, Integrated Optics, and Their Military Applications* (1977); RAY BONDS (ed.), *The Modern U.S. War Machine: An Encyclopedia of American Military Equipment and Strategy.* rev. ed. (1987); and, for a more general view. L.H. GANN, *The Defense of Western Europe* (1987).

(Ed.)

The Theory and Conduct of War

War in the popular sense is a conflict among political groups involving hostilities of considerable duration and magnitude. In the usage of social science certain qualifications are added. Sociologists usually apply the term to such conflicts only if they are initiated and conducted in accordance with socially recognized forms. They treat war as an institution recognized in custom or in law. Military writers usually confine the term to hostilities in which the contending groups are sufficiently equal in power to render the outcome uncertain for a time. Armed conflicts of powerful states with primitive peoples are usually called pacifications, military expeditions, or explorations; with small states, they are called interventions or reprisals; and with internal groups, rebellions or insurrections. Such incidents, if the resistance is sufficiently strong or protracted, may achieve a magnitude that entitles them to the name "war."

This article is in two major sections. The first treats the social sciences of war, such as law, economics, and theories of the causes and prevention of war. The second section presents the military arts and sciences, such as strategy, tactics, logistics, and intelligence.

War is treated in several other *Macropædia* articles. For the relation between diplomacy and war, see INTERNATIONAL RELATIONS, 20TH-CENTURY. For the weapons of war, see WAR, THE TECHNOLOGY OF. For a history of World Wars I and II, see WORLD WARS, THE. Other wars are covered in the history sections of articles on the relevant countries or regions—*e.g.*, for the American Civil War, see UNITED STATES OF AMERICA; for the Punic Wars, see GREEK AND ROMAN CIVILIZATIONS, ANCIENT.

For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* section 544, and the *Index.*

The article is divided into the following sections:

THE INSTITUTION OF WAR

Theory of war

In all ages war has been an important topic of analysis. In the latter part of the 20th century, in the aftermath of two world wars and in the shadow of nuclear, biological, and chemical holocaust, more has been written on the subject than ever before. Endeavours to understand the nature of war, to formulate some theory of its causes, conduct, and prevention, are of great importance, for theory shapes human expectations and determines human behaviour. The various schools of theorists are generally aware of the profound influence they can exercise upon life, and their writings usually include a strong normative element, for, when accepted by politicians, their ideas can assume the characteristics of self-fulfilling prophecies.

The analysis of war may be divided into several categories. Philosophical, political, economic, technological, legal, sociological, and psychological approaches are frequently distinguished. These distinctions indicate the varying focuses of interest and the different analytical categories employed by the theoretician, but most of the actual theories are mixed because war is an extremely complex social phenomenon that cannot be explained by any single factor or through any single approach.

EVOLUTION OF THEORIES OF WAR

Reflecting changes in the international system, theories of war have passed through several phases in the course of the past three centuries. After the ending of the wars of religion, about the middle of the 17th century, wars were fought for the interests of individual sovereigns and were limited both in their objectives and in their scope. The art of maneuver became decisive, and analysis of war was couched accordingly in terms of strategies. The situation changed fundamentally with the outbreak of the French Revolution, which increased the size of forces from small professional to large conscript armies and broadened the objectives of war to the ideals of the revolution, ideals that appealed to the masses who were subject to conscription. In the relative order of post-Napoleonic Europe the mainstream of theory returned to the idea of war as a rational, limited instrument of national policy. This approach was best articulated by the Prussian military theorist Carl von Clausewitz in his famous classic *On War* (1832–37).

War as a rational instrument

World War I, which was "total" in character because it resulted in the mobilization of entire populations and economies for a prolonged period of time, did not fit into the Clausewitzian pattern of limited conflict, and it led to a renewal of other theories. These no longer regarded war

as a rational instrument of state policy. The theorists held that war, in its modern, total form, if still conceived as a national state instrument, should be undertaken only if the most vital interests of the state, touching upon its very survival, are concerned. Otherwise, warfare serves broad ideologies and not the more narrowly defined interests of a sovereign or a nation. Like the religious wars of the 17th century, war becomes part of "grand designs," such as the rising of the proletariat in communist eschatology or the Nazi doctrine of a master race.

Some theoreticians have gone even further, denying war any rational character whatsoever. To them war is a calamity and a social disaster, whether it is afflicted by one nation upon another or conceived of as afflicting humanity as a whole. The idea is not new—in the aftermath of the Napoleonic Wars it was articulated, for example, by Tolstoy in the concluding chapter of *War and Peace* (1865–69). In the second half of the 20th century it gained new currency in peace research, a contemporary form of theorizing that combines analysis of the origins of warfare with a strong normative element aiming at its prevention. Peace research concentrates on two areas: the analysis of the international system and the empirical study of the phenomenon of war.

World War II and the subsequent evolution of weapons of mass destruction made the task of understanding the nature of war even more urgent. On the one hand, war has become an intractable social phenomenon, the elimination of which seems to be an essential precondition for the survival of mankind. On the other hand, the use of war as an instrument of policy is calculated in an unprecedented manner by the nuclear superpowers, the United States and the Soviet Union. War also remains a stark but rational instrumentality in certain more limited conflicts, such as those between Israel and the Arab nations. Thinking about war is, consequently, becoming increasingly more differentiated because it has to answer questions related to very different types of conflict.

Definitions of war Clausewitz cogently defines war as a rational instrument of foreign policy: "an act of violence intended to compel our opponent to fulfill our will." Modern definitions of war, such as "armed conflict between political units," generally disregard the narrow, legalistic definitions characteristic of the 19th century, which limited the concept to formally declared war between states. Such a definition includes civil wars but at the same time excludes such phenomena as insurrections, banditry, or piracy. Finally, war is generally understood to embrace only armed conflicts on a fairly large scale, usually excluding conflicts in which fewer than 50,000 combatants are involved.

THE CAUSES OF WAR

Contemporary theories of the causes of war divide roughly into two major schools. One attributes war to certain innate biological and psychological factors or drives, the other attributes it to certain social relations and institutions. Both schools include optimists and pessimists concerning the preventability of war.

Biological theories. Theories centring upon man's innate drives are developed by ethologists, who draw analogies from animal behaviour, and also by psychologists and psychoanalysts.

Ethology. Ethologists start with the persuasive argument that study of animal warfare may contribute toward an understanding of war as employed by man. The behaviour of monkeys and apes in captivity and of young children, for example, shows basic similarities. In both cases it is

Aggressive behaviour in animals possible to observe that aggressive behaviour usually arises from several drives: rivalry for possession, the intrusion of a stranger, or frustration of an activity. The major conflict situations leading to aggression among animals, especially those concerning access of males to females and control of a territory for feeding and breeding, are usually associated with patterns of dominance.

The analogies of animal to human behaviour drawn by many ethologists, however, are severely questioned by their more restrained colleagues as well as by many social scientists. The term aggression, for example, is imprecisely and inconsistently used, often referring merely to the largely symbolic behaviour of animals involving such signals as grimaces.

Observed animal behaviour can be regarded as a possible important source of inspiration for hypotheses, but these must then be checked through the study of actual human behaviour. As this has not yet been adequately done, the hypotheses advanced have little foundation and are merely interesting ideas to be investigated. Further, human behaviour is not fixed to the extent that animal behaviour is, partly because man rapidly evolves different patterns of behaviour in response to environmental factors, such as geography, climate, and contact with other social groups. The variety of these behaviour patterns is such that they can be used on both sides of an argument concerning, for example, whether or not men have an innate tendency to be aggressive.

Two particularly interesting subjects studied by ethologists are the effects of overcrowding on animals and animal behaviour regarding territory. The study of overcrowding is incomplete, and the findings that normal behaviour patterns tend to break down in such conditions and that aggressive behaviour often becomes prominent are subject to the qualification that animal and human reactions to overcrowding may be different. Ethologists have also advanced plausible hypotheses concerning biological means of population control through reduced fertility that occurs when animal populations increase beyond the capacity of their environment. Whether such biological control mechanisms operate in human society, however, requires further investigation.

Findings concerning the "territorial imperative" in animals—that is, the demarcation and defense against intrusion of a fixed area for feeding and breeding—are even more subject to qualification when an analogy is drawn from them to human behaviour. The analogy between an animal territory and a territorial state is obviously extremely tenuous. In nature the territories of members of a species differ in extent but usually seem to be provided with adequate resources, and use of force in their defense is rarely necessary, as the customary menacing signals generally lead to the withdrawal of potential rivals. This scarcely compares with the sometimes catastrophic defense of the territory of a national state.

Psychology. One school of theorists has postulated that the major causes of war can be found in man's psychological nature. Such psychological approaches range from very general, often merely intuitive assertions regarding human nature, to complex analyses utilizing the concepts and techniques of modern psychology. The former category includes a wide range of ethical and philosophical teaching and insights, including the works of such figures as St. Augustine and the 17th-century Dutch philosopher Spinoza.

Psychological maladjustments Modern writers utilizing psychological approaches emphasize the significance of psychological maladjustments or complexes and of false, stereotyped images held by decision makers of other countries and their leaders. Some psychologists posit an innate aggressiveness in man. Others concentrate upon public opinion and its influence, particularly in times of tension; others stress the importance of decision makers and the need for their careful selection and training. Most believe that an improved social adjustment of individuals would decrease frustration, insecurity, and fear and would reduce the likelihood of war. All of them believe in the importance of research and education. Still, the limitations of such approaches derive from their very generality. Also, whether the psychological premises are optimistic or pessimistic about the nature of man, one cannot ignore the impact upon human behaviour of social and political institutions that give man the opportunities to exercise his good or evil propensities and to impose restraints upon him.

Social theories. Whereas psychological explanations of war contain much that seems to be valid, they are insufficient because man behaves differently in different social contexts. Hence many thinkers have sought their explanations in these contexts, focusing either on the internal organization of states or on the international system within which these operate.

The most voluminous and influential theories attributing war to the nature of the state fall into two broad streams, which can be loosely called liberal and socialist.

Liberal analyses. The early or classical liberals of the 18th and 19th centuries distinguished three basic elements in their analysis—individuals, society, and the state—and regarded the state as the outcome of the interaction of the former two. They assumed that society is self-regulating and that the socioeconomic system is able to run smoothly with little interference from the government. Economy, decentralization, and freedom from governmental control were the classical liberal's main concerns, as shown particularly clearly in the writings of John Stuart Mill. They accepted the necessity of maintaining defense but postulated the existence of a basic harmony of interests among states, which would minimize the incidence of wars. Economic cooperation based upon an international division of labour and upon free trade would be in the interests of everybody—commerce would be the great panacea, the rational substitute for war.

In explanation of wars that did occur, however, liberals emphasized a variety of factors. First, they focused on autocratic governments, which were presumed to wage war against the wishes of peacefully inclined people. It thus became a major tenet of liberal political philosophy that war could be eliminated by introducing universal suffrage because the people would surely vote out of office any belligerently inclined government. From the early American pamphleteer Thomas Paine onward, a major school of liberals supported republicanism and stressed the peaceful impact of public opinion. Although they could not agree about actual policies, they stressed certain general ideas concerning relations between states, paralleling their laissez-faire ideas of the internal organization of the state with ideas of a minimum amount of international organization, use of force strictly limited to repelling aggression, the importance of public opinion and of democratically elected governments, and rational resolution of conflicts and disputes. Later in the course of the 19th century, however, and especially after World War I, liberals began to accept the conclusion that an unregulated international society did not automatically tend toward peace and advocated international organization as a corrective.

Socialist analyses. Whereas liberals concentrated on political structures, regarding them as of primary importance in determining the propensity of states to engage in war, socialists turned to the socioeconomic system of states as the primary factor. Early in the 20th century the two streams did, to some extent, converge, as evidenced by the fact that the English radical liberal John Hobson explained wars in terms later adopted by Lenin.

Marxian class conflict Karl Marx attributed war not to the behaviour of states but to the class structure of society. To him wars occurred not as an often voluntary instrument of state policy but as the result of a clash of social forces. To Marx the state was merely a political superstructure; the primary, determining factor lies in the capitalist mode of production, which leads to the development of two antagonistic classes: the bourgeoisie and the proletariat. The bourgeoisie controls governmental machinery in its own interests. In its international relations, the capitalist state engages in wars because it is driven by the dynamism of its system—the constantly growing need for raw materials, markets, and supplies of cheap labour. The only way to avoid war is to remove its basic cause, by replacing capitalism with socialism, thus abolishing both class struggle and states. The Marxist doctrine, however, gave no clear guidance about the interim period before the millennium is reached; and the international solidarity of the proletariat proved a myth when war broke out in 1914, facing the European Social Democratic parties with the problem of adopting an attitude to the outbreak of the war. The Second International of working-class parties had repeatedly passed resolutions urging the working classes to bring pressure upon their respective governments to prevent war, but, once war had broken out, each individual party chose to regard it as defensive for its own state and to participate in the war effort. This was explained by Lenin as being due to a split in the organization of the proletariat that

could be overcome only through the activity of a rigidly organized revolutionary vanguard.

Socialists in the West turned increasingly, although in varying degrees, to revisionist interpretations of Marxism and returned to their attempts to revise socioeconomic structures through evolutionary constitutional processes, seeing this as the only possible means of preventing wars. In the Soviet Union the socialist theory of war changed as the new communist regime responded to changes in circumstances. Soviet theoreticians have distinguished three major types of war: between capitalist states, between capitalist and socialist states, and colonial wars of liberation. The internecine wars among capitalist states are supposed to arise from capitalist competition and imperialist rivalries, such as those that led to the two world wars. They are desirable, for they weaken the capitalist camp. A war between capitalist and socialist states is one that clearly expresses the basic principle of class struggle and is, therefore, one for which the socialist states must prepare. Finally, wars of colonial liberation can be expected between subjugated people and their colonial masters.

The weakness of the theory is that the two major expected types of war, the intracapitalist and the capitalist–socialist, have not materialized as frequently as Soviet theoreticians predicted. Further, the theory failed to analyze adequately the situation in the Soviet Union and in the socialist camp. Even in communist countries, nationalism seems to have proved more powerful than socialism: "national liberation" movements have appeared and have had to be forcibly subdued in the Soviet Union, despite its communist regime. Also, war between socialist states is not unthinkable, as the doctrine indicates: only the colossal preponderance of Soviet forces prevented a full-scale war in 1956 against Hungary and in 1968 against Czechoslovakia; war between the Soviet Union and the People's Republic of China was a serious possibility for two decades after the Sino-Soviet split in 1962; and armed conflict erupted between China and Vietnam after the latter country became the most powerful in Southeast Asia. Finally, the theory does not provide for wars of liberation against socialist states, such as that conducted by the Afghan mujahideen against the Soviet Union from 1979 to 1989.

Nationalism. Many theories claim or imply that wars result ultimately from the allegiance of men to nations and from the intimate connection between the nation and a state. This link between the nation and the state is firmly established by the doctrine of national self-determination, which has become in the eyes of many the major basis of the legitimacy of states and the major factor in their establishment and breakup. It was the principle on which the political boundaries of eastern Europe and the Balkans were arranged after World War I and has been the principal slogan of the anticolonial movement of the 20th century, finding expression in Chapter I, article 1, of the Charter of the United Nations in the objective of "self-determination of peoples," as well as in the more specific provisions of Chapters XI and XII. It is this intimate link between nationalism and statehood that renders them both so dangerous. The rulers of a state are ultimately governed in their behaviour by what is loosely summed up as the "national interest," which occasionally clashes directly with the national interests of other states. National self-determination

The ideal of the nation-state is never fully achieved. In no historical case does one find all members of a particular nation gathered within one state's boundaries. Conversely, many states contain sizable national minorities. This lack of full correlation has frequently given rise to dangerous tensions that can ultimately lead to war. A government inspired by nationalism may conduct a policy aiming at the assimilation of national minorities, as was the general tendency of central and eastern European governments in the interwar period; it may also attempt to reunite the members of the nation living outside its boundaries, as Adolf Hitler did. National groups that are not in control of a state may feel dissatisfied with its regime and claim self-determination in a separate state, as demonstrated in the attempt to carve Biafra out of Nigeria and the separation of Bangladesh from Pakistan.

There is no rational basis for deciding on the extent to which the self-determination principle should be applied in allowing national minorities to break away. As a rule, the majority group violently opposes the breakaway movement. Violent conflicts can ensue and, through foreign involvement, turn into international wars. No suitable method has been found for divorcing nationalism from the state and for meeting national demands through adequate social and cultural provisions within a larger unit. Such an attempt in the Austro-Hungarian Empire before its dissolution in World War I failed. Whether the Soviet Union will be permanently successful in containing its large proportion of national minorities remains to be seen.

Nationalism not only induces wars but, through the severity of its influence, makes compromise and acceptance of defeat more difficult. It thus tends to prolong the duration and to increase the severity of wars. Possibly, however, this is the characteristic only of new, immature nationalisms, for nationalism has ceased to be a major cause of conflict and war among the nations of western Europe.

Nationalism is but one form of ideology: in all ages people seem to develop beliefs and try to proselytize others. Even within particular ideological groups schisms result in conflicts as violent as those between totally opposed creeds, and heretics are often regarded as more dangerous and hostile than opponents. As long as individual states can identify themselves with explosive differences in beliefs, the probability of a war between states is increased, and its intensity is likely to be greater.

Special-interest groups. Whereas some theories of war regard the state as an undifferentiated whole and generalize about its behaviour, other theorists are more sociologically oriented and focus on the roles played within the state by various special-interest groups.

A distinction is made by these theorists between the great mass of people and those groupings directly involved or influential with government. The people, about whose attitudes adequate knowledge is lacking, are generally assumed to be taken up with their daily lives and to be in favour of peace. The influential groups, who are directly involved in external affairs and, hence, in wars, are the main subject of analysis. Warlike governments dragging peace-loving people into international conflict is a recurrent theme both of liberal and socialist analyses of war. Some writers have gone to the length of postulating a continuous conspiracy of the rulers against the ruled that can be traced to prehistoric times, when priests and warriors combined in the first state structures. Most writers, however, narrow the field and seek an answer to the question of why some governments are more prone to engage in war than others; and they generally find the answer in the influence of important interest groups that pursue particular and selfish ends.

The chief and most obvious of such groups is the military. Military prowess was a major qualification for political leadership in primitive societies; the search for military glory as well as for the spoils of victory seems to have been one of the major motivations for war. Once the military function became differentiated and separated from civilian ones, a tension between the two became one of the most important issues of politics. The plausible view has generally been held that the military strive for war, in which they attain greater resources and can satisfy their status seeking and sometimes, also, an aspiration for direct and full political power. In peacetime, the military are obviously less important, are denied resources, and are less likely to influence or attain political power directly. At the same time, a second, although usually subsidiary, consideration of the military as a causal agent in war holds that an officer corps is directly responsible for any fighting and is thus more aware of its potential dangers for its members and for the state as well. Although intent on keeping the state in a high state of preparedness, the military may be more cautious than civilians about engaging in war. It is often held, however, that increased military preparedness may result in increased tensions and thus indirectly lead to the outbreak of war.

Closely allied are theories about groups that profit from wars economically—capitalists and the financiers, espe-cially those involved in industries catering to war. All of these play a central part as the villains of the piece in socialist and the liberal theories of war, and even those not subscribing to such theories do not deny the importance of military-industrial complexes in countries in which large sectors of the economy specialize in war supplies. But, although industrialists in all of the technologically advanced systems are undoubtedly influential in determining such factors as the level of armaments to be maintained, it is difficult to assume that their influence is or could be decisive when actual questions concerning war or peace are being decided by politicians.

Finally, some scientists and technologists constitute a new, much smaller, but important group with special interests in war. To some extent one can generalize about them, although the group is heterogeneous, embracing as it does nuclear scientists, space researchers, biologists and geneticists, chemists, and engineers. If they are involved in defense work, they all share the interest of the military in securing more resources for their research: without their military applications, for example, neither nuclear nor space research would have gone ahead nearly as fast as it has. War, however, does not enhance the status and standing of scientists; on the contrary, they come under the close control of the military. They also usually have peaceful alternatives to military research, although these may not be very satisfactory or ample. Consequently, although modern war technology depends heavily upon scientists, and although many of them are employed by governments in work directly or indirectly concerned with this technology, scientists as a group are far from being wedded to war. On the contrary, many of them are deeply concerned with the mass destruction made possible by science and participate in international pacifist movements.

THE CONTROL OF WAR

The international environment within which states and the people within them operate is regarded by many theorists as the major factor determining the occurrence and the nature of wars. War remains possible as long as individual states seek to ensure self-preservation and to promote their individual interests and—in the absence of a reliable international agency to control the actions of other states—rely on their own efforts. It is no accident that reforms of the international system figure prominently in many prescriptions for the prevention of war. Whereas the reform of human propensities or of the state is bound to be a long, drawn-out affair, if it is at all possible, relatively straightforward partial reforms of the international system may produce significant restraints upon resorting to war, and a thorough reform could make war impossible.

Some theorists, being more optimistic about the nature of states, concentrate upon the removal of the fear and suspicion of other states, which is characteristic of the present as well as of all historical political systems; others, being less optimistic, think mainly of possible controls and restraints upon the behaviour of states. The underlying reasoning of both parties is generally similar. If individual states in competitive situations are governed by a short-term conception of their interests, acute conflicts between them will occur and will show a strong tendency to escalate. Thus, one state erects a tariff barrier to protect its industry against the competition of a trade partner, and the partner retaliates, the retaliatory interaction being repeated until the two countries find themselves in a trade war. Armaments races show a similar tendency to escalate, particularly so in an age of rapid technological change. The economic and the scientific efforts necessary to avoid falling behind rivals in the invention and development of rapidly improving weapons of mass destruction have already reached unprecedented heights.

And yet, neither trade wars nor arms races necessarily end in violent conflict; there seem to be operating some restraining and inhibiting factors that prevent an automatic escalation. Much of the theory of war concerns itself with the identification, improvement, and development of these restraining factors.

Diplomacy. The outcome of starkly competitive behaviour leading to wars is clearly against the interests of

Military-industrial complex

Restraining national self-interest

states, and it is rational for them to seek more desirable outcomes. If competitive behaviour is dangerous, theorists seek for alternative methods of cooperative behaviour that would not jeopardize the interests of the state through exposing it to the possibly less cooperative behaviour of others. Some theorists concentrate upon improving the rationality of the decision-making of individual states through a better understanding of the international environment, through eliminating misperceptions and irrational fears, and through making clear the full possible costs of engaging in war and the full destructiveness of an all-out war, possible in our age.

Balance of power

The relative paucity of wars and their limited nature throughout the century following the Napoleonic Wars (1815–1914) have stirred great theoretical interest in the nature of the balance-of-power system of that period—that is, in the process by which the power of competing groups of states tended toward a condition of equilibrium. Contributing to the successful operation of the balance-of-power system of the 19th century were relatively slow technological change, great diversionary opportunities for industrial and colonial expansion, and the ideological and cultural homogeneity of Europe. Pursuit of a balance of power is a way of conducting foreign policy that is perhaps less prone to war than other types of policy because, instead of indiscriminately increasing their power, states increase it only moderately, so as not to provoke others; and instead of joining the strongest, they join the weaker side in order to ensure balance. States in a balance-of-power system must, however, be ready to abide by constraints upon their behaviour in order to ensure stability of the system.

The application to international relations of a branch of mathematics—game theory—that analyzes the strategy of conflict situations has provided a new tool of analysis. In state interaction, as in any game situation, one side's strategy generally depends upon that side's expectations of the other side's strategy. If all sides in a game are to maximize their chances of a satisfactory outcome, it is necessary that some rational rules of behaviour be conceptualized and agreed upon, and this idea of a set of rational rules can be applied to competing states in the international system. Game theorists distinguish antagonistic situations called zero-sum games in which one state's gain can be only at the expense of another state because the "payoff" is fixed. Even then a mutually acceptable distribution of gains can be rationally reached on the basis of the "minimax" principle—the party in a position of advantage satisfies itself with the minimum acceptable gain because it realizes that the other party, in a position of disadvantage, would yield on the basis of its possible minimum loss but would violently oppose a distribution even more to its detriment. In other situations called non-zero-sum games, the payoff is not constant but can be increased by a cooperative approach; the gain of one participant is not at the cost of another. The contestants, however, have to agree about the distribution of the gain, which is the product of their cooperation.

The theory of games is the foundation of theories of bargaining that analyze the behaviour of individual states in interaction. Diplomacy based upon such theories is less likely to lead to war. Policymakers pursuing such strategies will conduct conflicts of the zero-sum type so that war is avoided. More than that, with some skill, such situations can be transformed into the non-zero-sum type by introducing additional benefits accruing from cooperation in other interactions and also, more generally, by eliminating the likelihood of war and, consequently, by reducing the costs of preparing for one.

Regional integration. Because wars within states have been eliminated through the establishment of suitable political structures, such as central governments that hold a monopoly of coercive power, many theories concentrate upon the establishment of parallel structures within the international context. Regional integration (cooperation in economic, social, and political affairs, as, for example, within the European Economic Community) and the establishment of security communities, such as the North Atlantic Treaty Organization, have made much greater advances than attempts at the reform of the entire, global international system.

Because conflicts among neighbours tend to be frequent, regional integration is an important advance toward reducing the incidence of war. Even if it were to become generally successful, however, regional integration would simply shift the problem of war to a different level: there would be fewer possibilities of war because intraregional conflicts would be contained, but interregional conflicts could still give rise to wars of much greater scope and severity. The phenomenon of war must, therefore, be analyzed at the universal level.

International law. Some of the most influential thinking about war and the international system has come from specialists in international law. All of them postulate that there exists an international society of states that accepts the binding force of some norms of international behaviour. These norms are referred to as international law, although they differ fundamentally from municipal law because no sovereign exists who can enforce them. Most international lawyers realistically accept that international law is, consequently, among rather than above states. It is, according to legal doctrine, binding on states, but unenforceable.

The problem of enforcement

International law concerns itself largely with two aspects of war: its legality and its regulation. (For the regulation of warfare, see below *Law of war.*) As far as the legality of war is concerned, there has arisen in the 20th century a general consensus among states, expressed in several international treaties, including the Covenant of the League of Nations, the Kellogg–Briand Pact of 1928, and the Charter of the United Nations, that resort to armed force, except in certain circumstances, such as self-defense, is illegal. Such a legalistic approach to the prevention of war, however, remains futile in the absence of a means of enforcement. The enforcement provisions of the Covenant of the League of Nations and those of the United Nations Charter, which entail the application of military and economic sanctions, have never been applied successfully, owing to political disagreement among the major powers. This underlines the fact that legal norms, to be effective, must reflect an underlying political reality.

The United Nations. The United Nations is charged with the maintenance of international peace and security. The several approaches to peace outlined in its Charter and developed in its practice are based upon and clearly reflect the cumulative development of the relevant theories of war.

Drawing heavily upon the experience of the League of Nations, the Charter develops three interrelated approaches: first, pacific settlement of disputes, which would leave nations with nothing to fight about; second, collective security, which would confront aggressors with too much to fight against; and third, disarmament, which would deprive them of anything substantial with which to fight.

Peaceful settlement of disputes. Pacific settlement of disputes is based upon the assumption that war is primarily a technique for settling disputes, although it can, of course, also serve other purposes, such as allaying fears and seeking status. Further assumptions are that war frequently comes about because of the unawareness of decision makers of the possibility of settling disputes peacefully to the mutual advantage of both sides—an unawareness due to mere ignorance, pride, lack of imagination, or selfish and cynical leadership. It is thus possible that international organizations can contribute to the prevention of wars by devising and institutionalizing alternative, peaceful techniques for the settlement of disputes and by persuading the states to use them.

The scope of this approach is limited, for states are notoriously reluctant to abide by impartial findings on matters they regard as being of vital importance. Hence, what the procedures really offer is a means of slowing down the progression of a dispute toward war, giving reason a chance to prevail.

Collective security. Collective security is an approach to peace involving an agreement by which states agree to take collective action against any state defined as an aggressor. Leaving aside the problems of settling disputes or enforcing

Collective action against aggressors

law or satisfying justice, it concentrates upon forestalling violence by bringing to bear an overwhelmingly superior international force against any aggressor. Although collective security, in somewhat different forms, played a prominent part in the League of Nations Covenant and is embodied in the United Nations Charter, it has completely failed in both cases. Failing an international government capable of ultimately determining the issues, nations have not managed to agree on an unequivocal definition of aggression, have not in practice accepted the principle that aggression must be acted against independently of the identity of the perpetrator, and, therefore, have not established the international collective security force envisaged in the Charter.

Disarmament. Disarmament and limitation of armaments are based upon the theory that states are inclined to strive for dominance in arms over any potential rivals, and that this leads to arms races that tend to end in war. The major besetting sin of this theory is that it often tends to confuse cause with effect. Although arms races develop momentum of their own, they are themselves the result of political tensions leading to war. In short, it is the tensions that cause war, not the arms races. To hold otherwise is to mistake a symptom for a cause. Hence, reducing the levels of armaments does not necessarily reduce these tensions. Furthermore, it is the instability of strategic balances, rather than their level, that leads to war; agreements about disarmament or limitation of armaments may easily disturb the existing precarious balance and, therefore, be actually conducive to war.

Limiting conflict. As these major approaches to peace envisaged in its Charter have not proved very fruitful, the United Nations has developed two new procedures aiming at the limitation of wars. First, "preventive diplomacy," largely comprising the diplomatic initiatives of the secretary-general and the stationing of peacekeeping forces, has served to contain local conflicts and to prevent escalation, especially the involvement of the superpowers. Second, although the General Assembly's recommendations have no legal binding force, they have become increasingly influential, for by the mid-1970s the assembly was becoming an important agency for what has been called the collective legitimization of state policies. Resort to war becomes more costly when a state is faced with the prospects of a collective condemnation. This new restraint upon war does not, however, act upon conflicts that the assembly may favourably regard as wars of colonial liberation. Nor could the assembly's disapproval be relied upon to deter states from waging war in pursuit of an interest they deemed to be truly vital.

World government. Both the shortcomings and the limited practicability of all the approaches to the elimination of war through the reform of the international system have driven many thinkers to accept the idea that war can only be abolished by a full-scale world government. No midway solution between the relative anarchy of independent, individual states and a world government with the full paraphernalia of legislative powers and of an overwhelming military force would provide a sufficiently stable international framework for the nations to feel that wars would not break out and thus stop them from behaviour that is often conducive to wars. In an age faced with the danger of a war escalating into a general extermination of mankind, the central importance of preserving peace is obvious and is generally accepted. But here the thinkers divide. Some press on from this analysis to the logical conclusion that mankind must, and, therefore, will establish a world government, and they advance ideas how best to proceed in this direction. Others regard the world government as completely utopian, no matter how logical and desirable it may be. Yet, in terms of actual policies, the adherents of the two schools do not necessarily divide. Whether they do or do not believe that world government is attainable, they do agree that the complex phenomenon of war represents a potential calamity of such a magnitude that all theorists must endeavour to understand it and to apply their understanding to the prevention and mitigation of war with all the means at their disposal.

(J.Fr./Ed.)

Forcible abolition of war (margin note)

Law of war

The law of war has come to mean that body of international law relating to the conduct of war and to the protection of the victims of war. Its aim is to limit the suffering caused to combatants and, more particularly, to those who may be described as the victims of war—that is, noncombatant civilians and those no longer able to take part in hostilities. Thus, the wounded, the sick, the shipwrecked, and prisoners of war also require protection by law.

The laws of war have found it difficult to keep up with rapid changes wrought by the development of ever-newer weapons and more technologically advanced warfare, with their attendant damage to the natural environment. It therefore becomes important constantly to supplement (but not to abolish) earlier treaties. This section shows how the process of supplementation has been carried out.

The law of war has also been taken to include limitations placed upon states on their use of armed force. No system of law can prevent a state (or, indeed, an individual) from using force in self-defense, and the limitations of this concept are also discussed in this section.

Law by treaty. In ancient times war was not subject to any control other than that exercised by the combatants themselves, and any limitations that they might have placed on their own actions on the battlefield would have been due to military necessity rather than any belief that to attack civilians or to kill prisoners of war was wrong—let alone illegal. The Viking invaders in the 11th century, for instance, knew no concept of sparing the civilian population from attack or pillage, and they did not generally protect and release captured enemy combatants. And there was no reason why they should: no treaties prohibiting brutal acts in battle had been negotiated between states, nor had there developed a uniform practice among states that considered themselves civilized to avoid such conduct. In order for such norms to develop, there had to come into existence a belief shared by a number of independent states that some limits should be placed on the methods and means of war among themselves—especially if wars were to be fought between Christian states. (Crusades against the infidel were not controlled by any similar concern.) In the Middle Ages in Europe the precepts of Christianity began to provide vague guidelines of conduct on the battlefield. In 1625 Hugo Grotius wrote *On the Law of War and Peace* (*De Jure Belli ac Pacis*), in which he explored the basic principles of the humanitarian treatment of the victims of war.

If civilians were to enjoy any protection, it would also become necessary clearly to distinguish them from the combatants. This could come only with the development of a professional army wearing a distinctive uniform and taking upon itself a code of chivalry. Certain actions would then become unchivalrous and would lead to heavy sanction from brother soldiers. Chivalry, however, did not protect the common soldier or the ordinary civilian, for whom notions of chivalry were considered inappropriate. Protection by rule of law for the lower orders had to await the acceptance of principles of humanity that took a distinctive form in the 19th century.

Until the 20th century there existed no principle of international law that limited the right of states to go to war. War was seen as an integral part of state sovereignty to be entered into for political reasons. There were, however, attempts to distinguish wars that were considered "just" from those which were "unjust." This was a Christian doctrine formulated by, among others, St. Augustine, but it was an extremely flexible one, enabling a state to describe its war as just at its own discretion. As a corollary, the enemy state would therefore be fighting an unjust war, and its soldiers could be treated in any manner by the state claiming to be fighting a just war. It was more than likely that all states involved in a single conflict would claim to be fighting for a just cause and would show an attendant lack of concern for the protection of those unable, through wounds or capture, to defend themselves.

The first
Geneva
Convention

The development of modern weapons that could cause unnecessary suffering to combatants, and the great strides made in battlefield medical care, led to a growing awareness that international cooperation was required to protect the wounded and sick. Henri Dunant, a Swiss citizen and founder of the Red Cross, was preeminent in leading a number of states to conclude the first Geneva Convention in 1864 to protect the wounded and sick. But the first attempt to codify the laws of war was drafted by Francis Lieber, a college professor in New York City. Promulgated to Union forces by President Abraham Lincoln during the American Civil War, the Lieber code was to have a profound effect on subsequent codifications of the laws of war. In 1868 the Declaration of St. Petersburg prohibited the use of explosive projectiles weighing less than 400 grams, while in 1899 two major treaties were concluded at The Hague, one concerning asphyxiating gases and another concerned with expanding bullets. The second Hague conference, in 1907, proved to be a milestone, producing 13 separate treaties. In 1925 the Geneva Gas Protocol was signed, prohibiting the use in war of asphyxiating, poisonous, or other gases and of bacteriological methods of warfare. This was followed in 1929 by two further Geneva Conventions, dealing with the wounded and sick and with prisoners of war. Following World War II yet another conference produced the four 1949 Geneva Conventions dealing, respectively, with the wounded and sick on land, with the wounded, sick, and shipwrecked at sea, with prisoners of war, and with civilians. Further treaties followed, including the 1954 Hague Convention on the Protection of Cultural Property, the 1977 United Nations Convention on Military or Any Other Hostile Use of Environmental Modification Techniques, and the two 1977 Protocols to the Geneva Conventions of 1949, extending the terms of the conventions to wars of national liberation and civil wars.

Law by custom. The laws of war are to be found not only in treaties entered into by states but also in customary international law, which is found in the actual practice of states and in the belief (called *opinio juris:* "opinion of the law") that that practice is in conformity with international law. Much of this customary international law has found its way into the various conventions described above. Therefore, it may properly be argued that, although a particular state is not a party to a certain treaty, it is nevertheless bound by the principle of customary international law codified in that treaty. Further, a treaty may have such wide acceptance that it can be said to reflect the practice of all states, and it may then bind all states as reflecting customary international law. As an example of this approach, the International Military Tribunal at Nürnberg in 1946 decided that the fourth Hague Convention of 1907, concerning the laws and customs of war on land, reflected customary international law; hence, its principles bound Germany even though some states, which were at war with Germany, were not parties to it.

Some areas of the laws of war are not covered by treaty provisions, making it necessary to turn to other sources of international law. However, it may be that a particular point has never arisen before. In this case the Martens Clause, which first appeared in one of the 1899 Hague Conventions (and has been repeated in virtually every major treaty since), avoids any lacuna in the law by providing the following:

> Until a more complete code of the laws of war has been issued, the High Contracting Parties deem it expedient to declare that, in cases not included in the Regulations adopted by them, the inhabitants and the belligerents remain under the protection and the rule of the principles of the law of nations, as they result from the usages established among civilized peoples, from the laws of humanity, and the dictates of public conscience.

Judicial decisions are also a source of the international laws of war. The International Military Tribunals at Nürnberg and Tokyo following World War II laid down many general principles that became widely accepted, but, in fact, following that conflict a large number of other tribunals were conducted by individual states to try those charged with war crimes. In addition, a Japanese court,

The legally
binding
effect of
custom

in the case of *Shimoda* v. *Japan* (1955), dealt with the legality in international law of the atomic bombing of Hiroshima and Nagasaki.

COMMENCING HOSTILITIES

The Covenant of the League of Nations in 1920 attempted to restrict, but not to prohibit, recourse to war. It provided that states should seek to settle their disputes peacefully by referring them to arbitration, judicial settlement, or to the Council of the League. The parties to the Covenant agreed that they would in no case resort to war until three months after the award by the arbitrators, the judicial decision, or the report by the council. It was not until the Kellogg–Briand Pact of 1928 that 63 states party to it renounced war as an instrument of national policy. This treaty was relied upon by the Nürnberg tribunal in establishing not only that there was an international crime of waging aggressive war but that international law also imposed individual liability.

Legally defining war. Two particular matters that were not referred to by either treaty were the meaning of the word war and the limits of any right of self-defense. The term war remained subjective, giving states liberty to withhold the term from their military adventures if they were so minded. (For example, in the fighting over Manchuria between Japan and China from 1937 to 1941, the Japanese refused to call the conflict a war.) As a concept, the term was left with little significance after the United Nations Charter of 1945, in article 2(4), prohibited "the threat or use of force against the territorial integrity or political independence of any State, or in any other manner inconsistent with the Purposes of the United Nations." Moreover, all the Geneva Conventions apply to armed conflicts, whether or not they are officially called wars. In the Falkland Islands conflict in 1982, for example, the United Nations Security Council (in Resolution 502) condemned the Argentine invasion of the islands as a breach of the peace, even though neither Argentina nor the United Kingdom had declared war. Upon capture by the enemy, combatants were entitled to the treatment prescribed by the third Geneva Convention of 1949.

Aggression. The Security Council of the UN is empowered by article 39 of the Charter to determine the existence of any threat to the peace, breach of the peace, or act of aggression. It may make recommendations or decide what measures (including the use of armed force) shall be taken. In practice, the Security Council often is unable to act because of the veto power possessed by its permanent members (the United States, the United Kingdom, the Soviet Union, France, and China), and it is unable to take action through the use of armed force because none of the agreements between individual states and the UN envisaged by the Charter were ever made.

In 1974, General Assembly Resolution 3314 defined and gave some examples of aggression. Article 3 gave, as examples, invasion or attack by armed forces of a state, military occupation, bombardment against the territory of another state, blockade of ports or coasts, action of a state in allowing its territory to be used for preparing an act of aggression against a third state, and the sending of armed bands, groups, irregulars, or mercenaries to carry out acts of armed force against another state. Other General Assembly resolutions, notably Resolution 2625 of 1970 (the Declaration on Principles of International Law Concerning Friendly Relations and Co-operation Among States in Accordance with the Charter of the United Nations), stress the prohibition on the use of force contained in article 2(4).

Lawyers lament the imprecise definition of force as prohibited by the Charter. Three concepts appear to be used virtually interchangeably: force (and threat of force), aggression, and armed attack (this last to be found in article 51, concerned with self-defense). Article 2(4) further confuses the issue by prohibiting force "against the territorial integrity or political independence of any State, or in any other manner inconsistent with the Purposes of the United Nations." This has led to arguments—as in the Corfu Channel case between Britain and Albania in 1949 and in the attack by Israeli aircraft against an Iraqi

Vague
definitions
of armed
force

nuclear reactor in 1981—that although there had been a use of force in certain cases, that force was not directed against the territorial integrity or political independence of any state or against the purposes of the UN. In the Corfu Channel case, Britain insisted that it had acted only to clear Albanian mines from an international strait, and in the Iraqi case Israel argued that it had destroyed a facility that might acquire an ability to make nuclear weapons that would then threaten Israel. The International Court of Justice condemned the first action and the Security Council, the second.

It may well be that any use of armed force outside the territory of a state is a breach of article 2(4) of the UN Charter, and that the term force as used here also means aggression. Any state that uses force, therefore, will be required to show that it is doing so not out of aggression but in self-defense.

Self-defense. Article 51 of the Charter states the following: "Nothing in the present Charter shall impair the inherent right of individual or collective self-defense if an armed attack occurs against a Member of the United Nations, until the Security Council has taken measures necessary to maintain international peace and security." In *Nicaragua* v. *United States* (1986), the International Court of Justice ruled that this passage confirmed the existence of the right of self-defense under customary international law. In 1837 the *Caroline* affair, a dispute between the United States and Britain over the crossing into U.S. territory by British troops fighting Canadian rebels, led to a general acceptance that any state wishing to show that it had acted in self-defense would need to show an instant, overwhelming necessity of self-defense that left no choice of means and no moment for deliberation. In addition, the act of self-defense would need to be in proportion to the force used against it.

It should be noted that article 51 mentions a right of individual as well as collective self-defense. Following the invasion of the Falkland Islands, the British government claimed that the sending of its task force and the subsequent military action against Argentine forces was in conformity with the right of individual self-defense under article 51. On the other hand, the United States argued in 1966 that its military assistance to South Vietnam was justified as collective self-defense. The United States also tried to argue, in the case brought by Nicaragua before the International Court of Justice in 1986, that its military and paramilitary activities against that country were in collective self-defense with Costa Rica, El Salvador, and Honduras. The court decided, however, that there "was no rule permitting the exercise of collective self-defense in the absence of a request by the State which regards itself as the victim of an armed attack." (At the relevant time, none of these three Central American states considered that an armed attack had occurred against it.) In addition, the court considered that, in order for the right of collective self-defense to apply, the attacked state would have to request assistance from the state claiming to act in collective self-defense with it. Because this had not occurred, the United States could not justify its actions against Nicaragua as collective self-defense under article 51 of the Charter.

It is not clear whether anticipatory self-defense is permitted under the Charter. Read literally, article 51 requires an armed attack actually to have occurred before a state can act in self-defense. If, however, the "inherent right" expressed in article 51 allows customary international law to be considered, then it may be argued that a state does indeed have a right of anticipatory self-defense. The Nicaragua case seemed to suggest this interpretation, and it was used very effectively by Israel in June 1967 when it destroyed much of the Egyptian air force on the ground prior to an anticipated Egyptian attack on Israel. The United States justified its air attack on military targets within Libyan cities in 1986 by claiming that such action was taken to prevent terrorist attacks on Americans in the future. Moreover, it may be argued that a state claiming to be acting in self-defense can take into account the accumulation of hostile acts that have been committed against it in assessing the proportionality of its response.

There is here a very fine line dividing anticipatory self-defense, which may be legally permissible, from reprisal, the prime object of which is to punish an alleged wrongdoing and which is not legally permissible. The destruction by Israel of 13 civilian aircraft in Beirut, Lebanon, in 1968 was condemned by the UN Security Council as a reprisal, since the raid was in retaliation for the attack on an Israeli aircraft at Athens in which one Israeli citizen was killed. (Because the Security Council is not a court of law, it does not automatically follow that its condemnation of military action signals its illegality.)

A further problem with the definition of self-defense in article 51 is the extent to which a state may intervene by military force into the territory of another state in order to rescue its nationals who are threatened there. In 1976 members of the Israeli Defense Force entered, without permission, the territory of Uganda to rescue Israeli nationals who had been hijacked while traveling on a civilian airliner by a terrorist organization and who were being kept hostage at Entebbe airport near Kampala. There was some evidence that the Ugandan authorities had lent some assistance to the hijackers. The Entebbe raid was not condemned by the Security Council, and many writers on international law considered the raid justifiable. Of course, there were a number of distinctive features that made this a clear-cut legal case: The Israelis used minimal military force against a state that appeared to be assisting terrorists, and they left as soon as their citizens were under their control. In the Grenada incident in 1983, the United States sent armed forces to recover U.S. citizens from the island when the government had ceased to exist after its principal members were killed. U.S. forces remained on the island until elections were held, and then they were withdrawn. The Grenada invasion may be less clearly justifiable than the Entebbe raid, but, because the United States (along with the armed forces of other states in the region) took action at the request of Grenada's governor-general, the invasion may have been justifiable under international law (although not all international lawyers would agree).

International and internal conflicts. *Regional action.* Chapter VIII of the UN Charter permits the existence of regional arrangements or agencies for dealing with such matters of international peace and security as are appropriate for regional action. It goes on to provide, in article 53, that no enforcement action shall be taken under regional arrangements or by regional agencies without the authorization of the Security Council. Article 54 states that the Security Council shall be kept informed of all such activities. On a number of occasions, states have justified the use of force (or the threat of force) under this part of the Charter, despite the lack of prior authorization from the Security Council, by arguing that the measures they took did not amount to enforcement action and therefore did not require the authorization of the Security Council. Thus, the United States, after stopping ships on the high seas in 1962 to search them for missiles or missile parts intended for Cuba, argued that this was not enforcement action since the regional arrangement (in this case, the Organization of American States) had merely made a recommendation to member states and had not rendered a decision that had to be enforced. A similar argument was used following the Grenada incident: this action, the United States declared, was not directed against a government but was merely carried out to restore law and order to the island under the aegis of the Organization of Eastern Caribbean States.

War by proxy. Armed conflict need not be, and often is not, of the traditional type—that is, a conflict between regular armed forces in the territory of one or more states. *Nicaragua* v. *United States* showed that an armed attack (which would give the attacked state the right to act in self-defense) must be understood as "including not merely action by regular armed forces across an international border, but also the sending by or on behalf of a state of armed bands, groups, irregulars or mercenaries, which carry out acts of armed force against another state of such gravity as to amount to an actual armed attack conducted by regular forces, or its substantial involvement therein." Therefore, if a state sent an armed band into another state

to depose its rulers or to attack civilians of that state, then the sending state would have committed an armed attack, giving the attacked state the right to act in self-defense. As discussed above, the response must be proportionate to the aggression; in assessing this, the accumulation of events may be taken into account.

Civil war.   The term civil war, although perhaps dated, is used here to mean a noninternational armed conflict. It therefore covers any internal conflict, whatever the motive for the fighting.

It is often difficult to determine whether a conflict is truly internal or international, since other states may be involved to some extent. If it is indeed an international armed conflict, then an attacked state may seek the military assistance of any other state, which will then be acting in collective self-defense with it. (An example of this was the Vietnam War, although, it should be said, many states regarded it as a civil war.) Also, if the conflict has become international, then the 1949 Geneva Conventions and the whole of the body of the laws of war will apply to the combatants as well as to civilians caught up in the conflict. Should the war be a civil one (which can properly be described as an armed conflict), international law would point to the nonintervention of other states, and only article 3 of each of the 1949 Geneva Conventions would apply (protecting only those not taking an active part in the hostilities). Further protection is given (mainly to those who do not take part in the conflict) by the second Protocol of 1977, which applies to civil wars in which dissident armed forces, under responsible command, exercise such control over a part of the territory of a contracting state as to enable them to carry out sustained and concerted military operations and to implement the Protocol. For these reasons, the Protocol would not apply to the conflicts in Northern Ireland or Spain, in which neither the Irish Republican Army nor the Basque separatists controlled any territory, while it would apply in the conflict in El Salvador, in which rebels controlled sizable areas of the countryside.

War of national liberation.   The first Protocol of 1977 provides that peoples fighting against colonial domination and alien occupation and against racist regimes in the exercise of their right of self-determination are to be treated as if they were engaged in an international armed conflict and not a civil war. There is considerable difficulty over the meaning of this phrase, and it may be difficult to apply in practice.

CONDUCTING HOSTILITIES

Although the Hague Conventions, concerning the conduct of hostilities, apply to the states that are party to them in the event of war, the various Geneva Conventions of 1949 (and the 1977 Protocols to them) come into operation where there is an armed conflict between two or more contracting parties even if a state of war is not recognized by one (or both) of them. They also apply to the occupation of another state's territory even if the occupation meets with no armed resistance. Since much of the Hague Conventions reflect customary international law, it can be assumed that these laws of war (or the *jus in bello*) also apply whether or not any declarations of war exist. In considering the legal conduct of a conflict, the laws of war take no account of its causes. This means that the combatants of the aggressor nation are owed the same rights as those of the attacked state.

The controls placed on the actual methods and means of war are to a large extent based on the Hague Conventions, but there are also a number of important provisions in the first Protocol of 1977, the 1954 Hague Convention on cultural property, and the 1981 Conventional Weapons Convention.

Lawful combatants.   Those who may lawfully take part in hostilities are those who would be entitled to prisoner-of-war status if captured. Any other person taking part in a conflict may be treated as an unprivileged belligerent, or a franc-tireur, and he may be punished if captured. Article 4 of the third Geneva Convention of 1949 and article 43 of the first Protocol of 1977 provide that a lawful combatant is generally a member of the armed forces of a state. The

term also includes members of the merchant marine and inhabitants of unoccupied territory who, on the approach of the enemy, spontaneously take up arms to resist the invading forces until the territory has been occupied.

A spy is in a unique position, since he is often a member of the armed forces of a state; but if he acts in disguise in the zone of operations of an enemy in order to obtain information to pass on to his own forces, he may be punished provided he has a trial.

A mercenary is not protected at all; he has the right to be neither a combatant nor a prisoner of war. A mercenary is defined in the first Protocol of 1977 (which neither the United Kingdom nor the United States has ratified) as a person who is specially recruited to take part in a conflict, who is motivated essentially by private gain, and who is paid substantially more than the ordinary armed forces of the state to which he has been recruited. He must not be a national of the recruiting state or a member of the armed forces of a party to the conflict.

Guerrilla fighters are not solely a modern phenomenon, although during and after World War II they became a common feature of armed conflicts, especially those occurring in the developing world. The third Geneva Convention of 1949 required what is called an organized resistance movement to possess four characteristics before its members could be treated as prisoners of war upon capture. These were: (1) being commanded by a person responsible for his subordinates, (2) having a fixed and distinctive sign recognizable at a distance, (3) carrying arms openly, and (4) conducting operations in accordance with the laws and customs of war. In time, it became apparent that two of these four conditions were difficult for guerrilla fighters to meet. Were guerrillas to wear a fixed and distinctive sign recognizable at a distance or carry arms openly, they could hardly operate with any safety in occupied territory. The first Protocol of 1977 made a number of important changes that bind those states that are parties to it. For example, one of the major problems with recognizing guerrilla fighters as lawful combatants is that they may not, in fact, distinguish themselves from the civilian population—in which case, all civilians are placed at risk. Therefore, article 43 of the Protocol requires all combatants to distinguish themselves from the civilian population while they are engaged in an attack or in a military operation preparatory to an attack. However, even if a combatant does not do this, he will still be entitled to treatment as a lawful combatant if he carries his arms openly during each military engagement and during such time as he is visible to the adversary while engaged in a military deployment preceding the launching of an attack in which he is to participate.

A member of the armed forces of a party to a conflict will lose his status as a prisoner of war upon capture if he commits an act of hostility while wearing civilian clothes. In the case of *Osman Bin Mohammed* v. *Public Prosecutor* (1968), the Privy Council in London held that members of the Indonesian armed forces who had landed in Singapore during an armed conflict between Indonesia and Malaysia were not entitled to be treated as prisoners of war after having placed a bomb in a civilian building that caused the deaths of civilians. This loss of prisoner status will also apply, among the states that are parties to the first Protocol of 1977, if their combatants do not at least carry their arms openly, as described above.

Limits on the methods and means of war.   *Weapons.* Article 22 of the Regulations Annexed to the Hague Convention of 1907 provides that "the right of belligerents to adopt means of injuring the enemy is not unlimited." This particular principle underpins much of the law in this area, and there are many examples of it. Article 23 of the same treaty, for instance, prohibits certain activities such as the employment of poison or poisoned weapons, killing or injuring enemy combatants treacherously, attacking those who have surrendered, or declaring that no quarter will be given. It also prohibits the employment of arms, projectiles, or material calculated to cause unnecessary suffering. One reason for this approach, as stated in the Declaration of St. Petersburg of 1868, is that "the only legitimate object which states should endeavour to

accomplish during war is to weaken the military forces of the enemy."

This principle explains, to some extent, the prohibition on the use of certain weapons. Hence, the use of chemical and bacteriological weapons was banned by the 1925 Geneva Protocol. By the Bacteriological Weapons Convention of 1972, states party to it agreed never in any circumstances to develop, produce, stockpile, retain, or acquire bacteriological or biological weapons or toxins. If a ban on chemical weapons came about, it would likely take the same form.

The legal status of nuclear weapons   The use of nuclear weapons against enemy combatants is not subject to any express prohibitions. A number of international lawyers, however, take the view that their use is implicitly prohibited by the principles stated above, because radiation effects can be considered not only a form of poison but also a weapon calculated to cause unnecessary suffering. The General Assembly of the United Nations condemned their use in Resolution 1653 of 1961, but the value of this resolution is considerably weakened by the fact that, of the nuclear-weapon states, only the Soviet Union voted for it. In *Shimoda* v. *Japan* (1983), a Japanese court held that the use of atomic weapons against Nagasaki and Hiroshima was contrary to international law, not merely because of the type of weapon used but because bombardment, by any means, of the civilian population of those two cities was contrary to the Hague Conventions of 1907.

Like nuclear weapons, incendiary weapons are not specifically banned unless used against the civilian population. It might be argued, however, that their use against enemy combatants (as opposed to military equipment) would infringe the 1925 Geneva Gas Protocol, since they could come within the prescription of "all analogous liquids, materials, or devices."

The Vietnam War illustrated the dangers that modern weapons can cause to the environment. The use in that conflict of chemical herbicides and other methods of deforestation, along with attempts to alter weather patterns, called the attention of the world to such activities. The result was the 1977 United Nations convention on environmental modification, which requires states not to engage in military or any other hostile use of environmental modification techniques having widespread, long-lasting, or severe effects. The first Protocol of 1977 also prohibits the employment of methods or means of warfare that are intended, or may be expected, to cause widespread, long-term, and severe damage to the natural environment. States are specifically directed by this protocol to consider whether any new weapons that they might develop would infringe any rules of international law.

On the seas, naval forces may attack enemy warships. The sinking of the Argentine warship *General Belgrano*, therefore, was not contrary to international law despite its being attacked outside the Total Exclusion Zone that the British government had declared around the Falkland Islands.

Civilians. According to customary international law, only members of the armed forces of a party to a conflict can take part in hostilities, and the law has always attempted to draw a clear distinction between the lawful combatant, who may be attacked, and the civilian, who may not.

One of the Fundamental Rules of International Humanitarian Law Applicable in Armed Conflicts, which were prepared by the International Committee of the Red Cross in 1978, requires parties to a conflict to distinguish at all times "between the civilian population and combatants in **Ban on attacking civilians**   order to spare civilian population and property. Neither the civilian population as such nor civilian persons shall be the object of attack. Attacks shall be directed solely against military objectives." Restrictions on the use of chemical or nuclear weapons against the civilian population have been discussed above. In addition, the 1981 Conventional Weapons Convention specifically prohibits the use of mines, booby traps, and other similar devices and incendiary weapons directed against the civilian population or used indiscriminately, and the first Protocol of 1977 imposes very detailed target restraints in order to protect civilians. For example, aerial bombardment engaged in for the sole purpose of terrorizing the civilian population is prohibited, and the use of aircraft to carry out such a role would therefore be illegal. Merchant ships may in limited circumstances be attacked, but they may not be sunk by a submarine without its first having placed passengers, crew, and ship's papers in a place of safety.

Neutrals. The fifth Hague Convention of 1907 declares that the territory of neutral powers is inviolable and that a neutral state has a duty to prevent a belligerent state from carrying the conflict to its territory. In particular, troops belonging to the army of a belligerent state who enter the territory of a neutral must be interned. Also, a neutral must act evenhandedly to all belligerent states; for this reason, the United Kingdom declared its neutrality in the war between Iran and Iraq (1980–88), refusing to sell either side military equipment that would have significantly enhanced its capability to prolong the conflict.

Neutral shipping may be stopped on the high seas (as occurred in the Iran–Iraq War when a British merchant vessel was stopped by an Iranian warship) to check on the carriage of contraband. In naval warfare, the 13th Hague Convention of 1907 bans belligerents from conducting military operations in the territorial waters of a neutral state, and neutrals themselves have duties imposed on them not to assist the warships of belligerent states.

Prohibited areas of combat. Military activities of any kind cannot be carried out on the Moon (the Moon Treaty of 1979), Antarctica (the Antarctic Treaty of 1959), or on the territory (including the airspace) or territorial waters of neutral states. In addition, nuclear weapons or other weapons of mass destruction cannot be orbited around the Earth (the Outer Space Treaty of 1967) or placed on the seabed (the Seabed Treaty of 1971).

Prisoners of war. The third Geneva Convention of 1949 provides the basic framework of protection accorded to a prisoner of war. He is protected from the moment he falls into the power of an enemy until his final release and repatriation. No form of coercion may be inflicted on him to secure information of any kind; he need only give his name, rank, date of birth, and serial number. When an Argentine army officer captured by British forces during the Falklands conflict was alleged to have been responsible for the disappearance of French and Swedish nationals in Argentina prior to the conflict, he could not be compelled to disclose information on the subject and was released.

A prisoner of war is entitled to decent and humane **The rights of prisoners of war** treatment, to be evacuated from the combat zone, and to be granted rights and duties as similar as possible to those of the armed forces of the detaining power. No reprisals may be taken against prisoners of war; they may not be treated in a way contrary to the Convention even though an enemy state treats its prisoners of war in such a way. Officers may not be compelled to work, and other ranks may not be compelled to do dangerous or unhealthy work. Article 52 of the third Convention of 1949 goes on to provide that the removal of mines or similar devices shall be considered dangerous labour.

In order to ensure that prisoners of war are accorded the treatment laid down in the Conventions, states must ensure that a protecting power is appointed to act on their behalf. A protecting power is a neutral state acceptable to the state that holds prisoners of war. There were no protecting powers appointed during the Vietnam War or the Iran–Iraq War, but in the Falklands conflict Switzerland acted for the United Kingdom and Brazil for Argentina. A state may allow the International Committee of the Red Cross (ICRC) to act as a substitute protecting power. The ICRC has, in addition, a right to visit prisoner-of-war camps.

Protecting powers (or the ICRC) must be kept informed if a prisoner of war is to be tried (rather than being given disciplinary punishment) for an offense, in order, for instance, that the protecting power might find the accused a lawyer. If the death penalty is imposed, it cannot be carried out for at least six months after the judgment and after sentence has been communicated to the protecting power. A prisoner of war may be tried for an offense committed prior to capture (such as a war crime), but he

is entitled to retain his status as a prisoner of war even if convicted.

The use of weapons against prisoners of war attempting to escape constitutes an extreme measure and is to be preceded by warnings. The detaining power must hold an inquiry into the death of a prisoner of war and notify the protecting power. Such an incident occurred in the Falklands conflict, when a British soldier shot and killed an Argentine prisoner of war whom he believed was attempting to escape. The resultant inquiry exonerated the soldier, and a report was passed to the ICRC.

At the conclusion of hostilities prisoners of war are to be repatriated. Problems occurred at the conclusion of the Korean War when a number of North Koreans did not wish to return. A repatriation commission was established in 1953, and remaining prisoners of war were transferred to it. It has become more common to repatriate able-bodied prisoners of war before the end of hostilities. To a limited extent this occurred in the Iran–Iraq War, but it was a major feature of the Falklands conflict.

Occupation. World War II illustrated that civilians in occupied territory were largely unprotected by the laws of war. In consequence, the fourth Geneva Convention of 1949 provided detailed rules for their protection. A pro- Legally protected persons under military occupation tected person is anyone who, at a given moment and in any manner whatsoever, finds himself, in case of a conflict or occupation, in the hands of a party to the conflict or occupying power of whom he is not a national. The inhabitants of occupied territory are, therefore, protected persons under the Convention; they are entitled to humane treatment and to respect for their person, honour, family rights, religion, manners, and customs. Article 34 of the fourth Convention specifically prohibits the taking of hostages and reprisals against them or their property. Article 49 prohibits the transfer of protected persons out of occupied territory unless, in a given area, the security of the population or imperative military reasons so demand. After the war of June 1967, Israel occupied territory in the West Bank, the Gaza Strip, and the Golan Heights, but it claimed that the fourth Convention did not apply to them. The United Nations took a different view in resolutions in 1988 when it specifically declared that the Convention was applicable to all the Palestinian and other Arab territories occupied by Israel since 1967. The resolutions went on to condemn a number of Israeli practices in these territories, such as the killing, wounding, and deportation of Palestinian civilians (who are protected persons under the fourth Convention), during uprisings against Israeli rule.

The occupying state may make such laws for occupied territory as enable it to carry out its obligations under the Convention, to maintain the orderly government of the territory, and to ensure its safety. At the same time, it must respect other laws in force before the occupation. Requisitions for the needs of the occupying army may be taken, but only on payment, and foodstuffs and medical supplies may be requisitioned only if the needs of the civilian population have been taken into account. If the supply of such items is inadequate for the needs of the civilian population, then the occupying state will be under an obligation to bring them into the territory. The Nürnberg trial concluded that "the German armies were to be fed out of Soviet territory, even if many millions of people were to starve to death." It is this type of conduct that the fourth Convention attempts to prevent.

Protected persons who are not members of the armed forces and who use force against occupying forces are not entitled to special treatment, since they are not entitled to prisoner-of-war status upon capture. The occupying state may place them on trial for breach of either the ordinary laws of the territory or the laws it has imposed. However, if it is to sentence such a person to death, it must take into account that the protected person does not owe the occupier any duty of allegiance. Also, a state that occupies territory does not thereby obtain good title to it. Various UN resolutions confirm this; a General Assembly resolution in November 1988 reaffirmed that the "occupation by Israel of the Palestinian territories since 1967, including Jerusalem, in no way changes the legal status of those territories."

CESSATION OF HOSTILITIES

Hostilities may be suspended pending negotiation between the parties. Negotiation may, or may not, be preceded by the display of a white flag, which merely means that one side wishes to enter into communication with the other. The parties may then enter into an armistice, and, when all matters are agreed, a peace treaty may be concluded. Of course, it is possible to end hostilities without any treaty; neither the Falklands conflict nor the Iran–Iraq War ended in this way, although an agreement sponsored by the UN provided for the withdrawal of Soviet troops from Afghanistan in 1989.

It has been shown that the acquisition of territory as a result of a war of aggression does not give title to that territory under international law. In the same way, a treaty by which a victor (who has started a war of aggression) requires a vanquished state to cede to it territory would not be considered a valid transfer of sovereignty over the territory concerned.

WAR CRIMES

The term war crime has no definite meaning. It was commonly thought of as a violation of the laws of war committed by a combatant or even a civilian. In 1945 the charter of the Nürnberg tribunal gave that court jurisdiction to try crimes against the peace (which consisted of waging a war of aggression), war crimes (that is, violations of the laws and customs of war), and crimes against humanity (such as the murder and ill-treatment of civilians). Twenty-two persons were charged at Nürnberg and 25 at the Tokyo tribunal, but many more were tried by tribunals established by Allied governments in territory they occupied at the conclusion of World War II. The tribunals Importance of the Nürnberg and Tokyo tribunals had a profound effect on the development of international law as it is concerned with the responsibility of both states and individuals for conduct leading to and during war. In particular, the tribunal confirmed that individuals could be held liable for a breach of international law: "Crimes against international law are committed by men, not by abstract entities, and only by punishing individuals who commit such crimes can the provisions of international law be enforced."

One problem associated with the tribunal was that of its jurisdiction. Did international law (upon which the framers of the charter relied) permit states to try the nationals of another state for committing crimes under international law in the territory of yet other states? The charter decided that it did, since it was concerned with offenses having no particular geographic location. A wider view of international law was taken in the case of *Attorney General of the Government of Israel* v. *Eichmann,* which was decided by the District Court of Jerusalem in 1961. Adolf Eichmann, head of the Jewish office of the Gestapo during World War II, was convicted of war crimes, crimes against the Jewish people, and crimes against humanity. Although the crimes were not committed on the territory of Israel (which at the time did not exist as a state), the court held that such acts could be tried by any state that had custody of the defendant. (Eichmann had, in fact, been abducted from Argentina by Israeli agents.)

The Nürnberg tribunal also had to consider arguments put forward by the defense. Many defendants pleaded that their actions were carried out on the orders of superiors. The framers of the charter realized that this was likely to be a major issue, and they added to the charter an article which stated that superior orders would not relieve a defendant of liability but could be considered in mitigation. For this reason no convictions were brought against those responsible for bombing Allied cities or for the waging of unrestricted submarine warfare.

The Nürnberg principles were affirmed by the United Nations in 1946. In 1948 the United Nations prepared a Convention on the Prevention and Punishment of the Crime of Genocide, and in 1968 it offered for signature a convention that removed the statute of limitations from war crimes and crimes against humanity.

The four Geneva Conventions of 1949 take a different Postwar conventions on war crimes approach to trying those responsible for breaches of the laws of war during an armed conflict. Each Convention

lists a number of "grave breaches," which include willful killing, torture or inhuman treatment, and the causing of great suffering or serious injury to body or health. States party to the Conventions undertook to enact legislation to try those suspected of grave breaches and to search for such persons. The United Kingdom, for instance, enacted the Geneva Conventions Act of 1957, making it a criminal offense for any person to commit a grave breach of the Conventions anywhere in the world. The first Protocol of 1977 adds to the list of grave breaches, such as making the civilian population or individual civilians the object of attack, launching an indiscriminate attack affecting the civilian population, the perfidious use of the distinctive emblem of the Red Cross, and the transfer of protected persons from occupied territory (as discussed above in relation to Israel).

The Protocol also provides for the establishment of fact-finding commissions to inquire into any allegation of a grave breach. Allegations of war criminality were made in regard to actions committed during the Korean War, the Vietnam War (especially the killing of prisoners of war), and the Iran–Iraq War, but no conviction for a grave breach of the Geneva Conventions has been recorded. Individual members of the armed forces may instead be tried by court-martial for a breach of their domestic penal or military law. For example, in 1947 a British army medical officer was convicted by court-martial for the ill-treatment of German nationals held when the United Kingdom occupied parts of Germany, and in 1971 a U.S. army lieutenant was convicted of murder for his part in the massacre of villagers in South Vietnam.   (P.J.R.)

Military law

All states require a code of laws and regulations for the raising, maintenance, and administration of their armed forces. All this may be considered the field of military law. The term, however, is generally confined to disciplinary military law, that part of the code that aims at and sanctions the maintenance of discipline in the armed forces. In the past this was also known by the name of martial law, a term that now has the meaning of military enforcement of order upon a civil population either in occupied territory or in time of disorder. Members of armed forces do not cease under modern conditions to have duties as citizens and as human beings. All systems of military law must aim to ensure that the soldier is in no way enabled to escape the obligations of his country's ordinary law or of international law as recognized in various conventions.

HISTORICAL DEVELOPMENT

The object of the disciplinary code is to ensure that the will of the commander is put into effect. Military law therefore traces its origins to the prerogative power of rulers. In Rome, just as a sector of civil law developed from the imperium of the magistrates, so did military law derive from the imperium of those same magistrates in their capacity as commanders of the military forces. The Roman historian Tacitus indicates that military justice in the 1st century AD was somewhat rough-and-ready and heavy-handed and varied much with the individual commander. But it became more formalized 400 years later in the Digest and Codex of the emperor Justinian. With the rise of the kingdoms of the Middle Ages, the maintenance of discipline was enforced by ordinances or articles of war issued by the sovereign or by a commander authorized by him at the beginning of each campaign. The earliest now extant are those of the English king Richard I in a charter of 1189 for the government of those going to the Holy Land.

With mercenary armies drawn from many nations in the wars of the 16th and 17th centuries, each national contingent tended to apply the articles of the supreme commander according to its own rules of procedure. The articles of war of Maurice of Nassau, prince of Orange, and Gustav II Adolf had a considerable influence on the national commanders who served under them, when they came to command elsewhere. In the English Civil Wars, the ordinances of the royalist and the parliamentary com-

Medieval articles of war (left margin)

manders were thus in the most part literally the same and in the next reign formed the basis of Prince Rupert's code of 1672. The famed discipline of Cromwell's army was due not to any improved code but to the fact that the articles were rigorously enforced. On the continent of Europe, the articles of Gustav Adolf continued to be followed until supplanted by the codification of the 19th century, which established throughout those countries a generally similar system that, with revision and amendments, continues to this day.

With the introduction of a standing army in England in 1689, Parliament aimed to prevent this force coming under complete control of the sovereign by a series of mutiny acts, normally passed annually, to which the prerogative articles were subordinate. By a statute of 1717 the power to make articles was embodied in the act. In the United States in 1775 and again in 1806, articles of war were adopted that were modeled upon the mutiny acts and articles then in force in Great Britain. In the British army, the articles of war were replaced in 1881 by an annually renewed Army Act (reformed in 1955), although they continued in the Royal Navy until 1957. In the United States they were replaced by the Uniform Code of Military Justice in 1951.

JURISDICTION

Persons subject to military law. The jurisdiction of military law is not necessarily confined to offenses injurious to the discipline of the forces committed by members of those forces. It extends in various countries in varying degrees to all offenses committed by members of the forces and to offenses injurious to discipline committed by persons who are not members of those forces.

Military personnel. In countries in which an obligation to military service exists, soldiers who fail to answer their initial call-up or report for duty are liable to military jurisdiction for such offenses as desertion or self-mutilation either because the military code makes such offenses applicable to them as a class of civilians (as in Belgium, France, Italy, and Israel) or because under the act introducing national service they are deemed to be enlisted on the dispatch of a calling-up notice (as was the case in Great Britain when conscription was in force). They continue to be liable for such offenses, even if not otherwise subject to military law, during authorized absence from the conscripted service or temporary reserve service. Reservists are also subject (as in Italy) to military jurisdiction for such offenses as treason, communicating with foreign countries, and revelation of official secrets. In Belgium, released soldiers remain liable for rebellion or offenses against superiors committed within one year of their release.

Legal status of conscripts (right margin)

Civilians. Civilians may become subject to military jurisdiction in any number of ways. In Italy and Turkey, for example, treason or rebellion can be dealt with under the military code, and in Norway breaches by a civilian of the Geneva Conventions of 1949 and their additional Protocols of 1977 are dealt with under military law. In other countries, civilians who instigate or participate in military crimes may themselves be triable under military law. In a number of countries, civilians within a war zone or theatre of active operations, or in conditions defined as a "state of siege," can come under military jurisdiction for offenses similar to those mentioned above—or even completely under military jurisdiction, as in Argentina.

In other countries, only civilians associated with the armed forces may be triable under service law. In Israel, for example, civilians who are employed by the army, or who have been provided with army weapons, are subject to military law, as are those held in army custody. Under British military law, civilians accompanying armed forces stationed in a foreign country (including families of soldiers as well as British civilians working for or with the services) are triable under offenses against the good order of the military community. In the United States, however, civilians—even those forming part of a service community abroad—cannot in peacetime be tried at all under the military process, though they may become subject to military jurisdiction in time of war. Austria and Spain

are among countries in which no civilian can be liable to military jurisdiction.

Prisoners of war. Also among those who fall under military jurisdiction are prisoners of war. Sometimes, as in France, Belgium, and Luxembourg, they are expressly included among those to whom the ordinary military law applies; elsewhere, special regulations concerning their behaviour and trial must be passed. Under the third Geneva Convention of 1949, prisoners of war must be tried by a military court, except where the laws of the belligerent expressly allow a member of the belligerent's armed forces to be tried by a civil court for the same offenses. Prisoners of war must not be sentenced to any penalties other than those which might be inflicted on members of the forces of the detaining power for the same act.

Offenses against military law. The military law of the Anglo-American countries and of countries deriving their military law from them, such as India and other independent members of the British Commonwealth, differs from that of the majority of the continental countries in that the latter tend to divide military offenses into two classes: crimes that are the subject of judicial punishment and, second, breaches of discipline that are subject only to administrative action. The former group of countries (and a few others, including most communist countries) recognize no such distinction, regarding all military offenses as crimes. Apart from offenses of a peculiarly military nature, such as mutiny, insubordination, desertion, and misconduct in action or in performance of service duties, when an act committed by a soldier constitutes an offense in the civil code, it will frequently constitute an offense of which military law takes cognizance. In the Soviet Union and Belgium, for example, all civil offenses committed by soldiers, except very minor ones, are tried by military court. In France, Germany, Austria, and Scandinavia, in peacetime, all crimes, military or civil, are dealt with by civil courts. Great Britain, Canada, and other countries include as military crimes all actions committed by soldiers anywhere that would be offenses against the criminal law of their own country, although the most serious of these cannot be tried by a military court unless committed abroad, or in India at specified Frontier Posts. In the United States, because of the differences between the criminal law of different states, certain civil crimes are specifically made offenses against the military code. All countries have rules to prevent the double jeopardy of an offender being punished for one act by both civil and military jurisdiction. Generally, when civil jurisdiction may be exercised, this takes precedence over military jurisdiction.

Differences between common-law and continental systems

PROCEDURE

Summary punishment. In both Anglo-American and continental systems, soldiers are subjected to penalties imposed summarily as well as to those imposed by courts. In the majority of countries, summary penalties can be inflicted only by officers not lower than the rank of captain, the commanding officer of the military unit being the principal source of discipline. The forms of punishment so inflicted are normally loss of privileges for a specified period, fines, or deprivation of liberty. Higher military commanders usually have power to deal summarily with officers (normally up to the rank of major), though in some countries these will not be liable to loss of liberty.

Appeal. Under the British and some other systems of military law, if a commanding officer has it in mind to award a punishment beyond a certain degree of severity (usually including deprivation of liberty), he must first offer the accused the option of being tried by a court-martial. Also, in Britain, the United States, and other common-law countries the accused may complain of unjust or unduly severe punishment to the commanding officer's superiors. Such complaints may proceed to the highest level, in effect achieving a review of the commanding officer's award. In other countries the soldier may appeal to a tribunal; in yet others, such as Norway and Sweden, he may have a right of appeal through the chain of military command up to a certain level (the brigade commander in Norway; in Sweden, the regimental commander) but, beyond that, to a tribunal (in Sweden, the county court).

Between summary action and trial. In the Anglo-American countries, offenses beyond a commanding officer's powers are dealt with by a service court (court-martial). In the continental countries, military crimes and similar offenses are also dealt with judicially. In the latter, however, there is an intermediate form of tribunal that deals with the more serious breaches of discipline and may impose punishments affecting a soldier's career, such as loss of rank or appointment, dismissal, or forfeiture of pension rights. In Germany, military courts of service, which also hear soldiers' complaints, may impose career sanctions. Also to be noted are the unit assemblies in the Soviet Union, which are general assemblies of all military members of a unit. All those attending are invited to comment on the behaviour under investigation. An elected tribunal, normally of five, decides whether the public examination is in itself sufficient educational corrective of the aberrant behaviour or whether the offender should be reported to a competent commander for disciplinary measures.

Examination by peers in the Soviet military

Court-martial. *Pretrial procedure.* Military courts follow judicial procedures no less formal than those of the higher civil courts. There is always some form of preliminary investigatory procedure that fills a role similar to that of the committal proceedings in the British legal system, the grand jury in the United States, and the juge d'instruction in continental systems. Under the British system, and those of Commonwealth and other countries deriving from it, it is the accused's commanding officer who is responsible for the conduct of this quasi-judicial investigation, having the evidence reduced to writing, considering it, and deciding whether it justifies his remanding the accused for trial by court-martial. Under other military legal systems, the preliminary investigation is likely to be in the hands of a military magistrate and set in motion by a military procurator, who corresponds to the official responsible in such countries for initiating civil prosecutions on the public behalf. In Israel, whose military judicial procedures otherwise derive from the British model, the responsibility for both the investigation and the decision to proceed to trial rests with a military advocate, the commanding officer being excluded altogether from the investigative process and forbidden to interfere with it.

Protecting the accused. Pending trial, all countries maintain a presumption of the accused's innocence. He must be allowed full facilities for preparing his defense, and there are normally safeguards provided to protect him from being held unjustifiably in arrest before trial. In some systems his arrest must be ordered and authorized by a magistrate, usually for a limited period only. Where the accused's commanding officer is empowered to authorize arrest, he is likely to be obliged to report the progress of the case at specified and frequent intervals to higher authority, so that the need to retain the accused in arrest can be constantly monitored.

Composition of the court. Courts-martial are generally composed, depending on the type of case, of between three and seven judges; these are usually military officers, though in some countries the membership of the court may include other ranks and even civilian judges. In the United States, for instance, the accused enlisted man may require that not less than one-third of the court be made up of enlisted men. In the Soviet Union the court includes popular assessors, elected from the ranks of the unit and holding office for two years. British military law provides for the court to include civilian crown servants when the accused is a civilian, one if the court is a district court-martial and two if the trial is by general court-martial.

The military courts of most countries embody at least one lawyer, who may be a legally qualified serving officer or a civilian and whose role may be either that of a participating member of the judicial tribunal (sometimes its president) or that of a legal adviser to a tribunal composed of lay military men. The judicial independence of the professional lawyers, where they serve as participating judges, is commonly safeguarded by their appointment on a fixed tenure of office. In Israel, for example, a legally qualified officer on a five- to seven-year tenure sits as president with two lay officers. The Belgian military court consists of a civilian judge on a three-year tenure sitting

The role of professional lawyers

with four serving officers. In Italy two permanent civilian judges sit with one military officer who is selected by lot for a two-month tour of duty as a member of the court. In France the military tribunal consists, in wartime, of two civil and three military judges (since 1983 French soldiers in peacetime have come entirely under civil jurisdiction). In the Soviet Union, the professional element is supplied by the presidents, vice presidents, and members of military courts, who are nominated by the Presidium of the Supreme Soviet; in courts of first instance it is one of these appointed professionals who sits with the two popularly elected assessors.

In those courts in which the lawyer sits as a legally qualified judge, he takes part with the other members of the tribunal in deliberating upon the court's finding, as is usually the custom in civil trials in their countries. The other mode of trial, in which the lawyer is advisory to a court-martial of laymen, is more common in countries accustomed to the Anglo-American mode of jury trial, where the professional judge, having instructed a lay fact-finding body (the jury) as to the principles of law they must apply, takes no part in their subsequent deliberations. In a similar manner, the legal adviser to the court-martial sums up the law and the facts in open court and then retires, leaving the members of the tribunal to their own discussions and returning only when they announce their finding. The adviser normally remains present during the court's subsequent discussions on sentence, but only as an

The judge advocate

adviser, having no vote. In Britain and the countries of the Commonwealth, this legal adviser to a court-martial is termed a judge advocate. The British judge advocate is almost always a member of the judicial staff of the judge advocate general, a civilian official responsible to the lord chancellor and, thus, entirely independent of the service authorities. Many Commonwealth countries also make use of a civilian judge advocate. In the United States the erstwhile legal adviser to the court-martial has been replaced by a military judge, who is a serving officer but is part of an independent military judiciary. When sitting with a court-martial, his functions remain advisory, much as already described; he has, however, also been given an alternative jurisdiction to sit, at the request of the accused, as the sole judge in the case, determining guilt or innocence and, in the event of a finding of guilty, passing sentence.

Courts of varying competence.   In some countries there are grades of courts-martial with varying competence as regards persons whom they may try or punishment they may impose. In the United States, Great Britain, and Canada, general courts-martial composed of not less than five officers with a legal adviser (military judge in the United States) may deal with all persons subject to military law and pass any sentence authorized by the code; special courts-martial (United States), district courts-martial (Britain), and disciplinary courts-martial (Canada) consist of at least three officers and have limited powers. In the Soviet Union there are inferior, intermediate, and superior courts. Although under the Anglo-American system, in cases of minor importance, prosecution and defense may be conducted by regimental officers of no legal qualifications, in the majority of countries, the prosecution will normally be in the hands of a legally qualified official, known variously as commissioner, fiscal general, auditor, or military procurator.

Counsel for the accused.   A soldier being dealt with summarily, or by disciplinary procedure that is not regarded as judicial action, is not usually defended—though this right has been introduced in The Netherlands, is under examination in the United Kingdom, and is not forbidden in West Germany, should the soldier so desire. In trials before military courts, all countries allow the accused to be assisted in his defense by an advocate, and in some countries this is compulsory. All countries permit the employment of qualified civilian lawyers. In Greece and the Soviet Union, the defense may be conducted by the family or friends of the accused. In the Soviet Union, additionally, such persons as representatives of syndicates and other social organizations may defend.

The stage at which a defender may operate varies. Nor-

mally, he may assist immediately after the first interrogation, when an accused is informed of his rights. He then has rights of intervention during the process of instruction and must be present at such features of it as the interrogation of the accused. In other countries (as in Greece), the defender has no part in the instruction and appears only at the trial.

Appeal.   *Appeal through the courts.*   Under the Anglo-American system, a court-martial's finding of guilty and its sentence must normally be confirmed by the military commander who convened the trial or by an officer superior to him. They are also subject to further review at higher levels in the military chain of command. The convicted soldier is entitled to petition the confirming officer and, subsequently, any reviewing authority against either the finding or the sentence. In some systems there may be, instead of or in addition to this right, a right of appeal from the court-martial to a superior military court. In most countries there is either an immediate or an ultimate right of appeal to a court of civilian judges—in Continental countries a Court of Cassation and in Britain a Courts-Martial Appeal Court consisting in practice of judges of the Criminal Division of the Court of Appeal. In both the United States and Britain, there can in some circumstances be a final appeal to the highest court in the land—namely, in the United States the Supreme Court and in Britain the House of Lords. In Israel, too, the right of appeal from courts-martial can extend to the Supreme Court.

Rights of the convicted soldier

In general, appeal courts are concerned only with the legality of conviction, not with matters of sentence, and the supreme courts only with points of law. Normally, only the defense can appeal, but sometimes, as in the Soviet Union, the prosecution too can appeal either against the original finding and sentence of the court-martial or on a question of law.

The ombudsman.   In a few countries, representations about conditions of service and applications for advice and help outside the normal service channels may be made through specific officials. In Norway a military ombudsman was introduced in 1952. This official sometimes raises questions on disciplinary and penal offenses. The first military ombudsman was probably in Sweden, established in 1915 to take note of the sentences of military courts, conditions in military prisons, and other matters of military administration. This office as such, however, was abolished in 1968, and the supervision of the military, including complaints by soldiers, became part of the responsibilities of one of four parliamentary ombudsmen. The route of appeal by way of an ombudsman or similar civilian official in those countries that have them (including, among others, Finland and West Germany) has developed into an effective means of protecting the rights of soldiers within the military system.

Wartime procedure.   Almost all countries, including those that leave the soldier in peacetime to an exclusively civilian jurisdiction, make provision for trial in time of war or emergency by military courts composed wholly or predominantly of soldiers. Sweden is an exception; even in wartime, military offenders can be tried only by the ordinary county courts. Where the normal peacetime military court is wholly or mainly composed of soldiers, provision may be made for fewer or for less-senior officers than would be called to constitute a court in peacetime. Procedure may be simplified, sometimes including an abridgment of the rights of appeal and an empowerment of the military commander to override these rights when military discipline and morale call for the immediate and exemplary execution of the penalty—including, in some cases, a death sentence.

LEGAL TRENDS

Since the 1950s and '60s there has been a trend toward the civilianization of military courts. France has joined Norway, Sweden, and West Germany in placing its servicemen in peacetime exclusively under civil jurisdiction. In countries that have not gone as far as this, the military court of first instance has come to include a substantial number—sometimes a majority—of civil judges. Neces-

The civilian-ization of military courts

sarily, this is possible only in countries whose armed forces are stationed entirely within (or within easy reach of) their own frontiers.

The 1950 European Convention on Human Rights, along with various rulings on its applications to military trials, have led some European countries to overhaul or amend their military judicial processes. This has had the aim of bringing them into compliance, in particular, with articles 5 and 6 of the Convention, which provide that no one may be deprived of his liberty save by a competent court and that the accused may declare his right upon a "criminal charge" to a "fair and public hearing by an independent and impartial tribunal established by law."

Both the European human rights convention and the United Nations Covenant on Civil and Political Rights expressly recognize that the right of free association may lawfully be restricted in the armed forces. Nevertheless, some countries (notably West Germany and The Netherlands) permit soldiers to form unions in order to safeguard and improve their working and economic conditions—though not to the extent of engaging in "industrial actions" such as strikes. Other countries allow servicemen to belong to unions appropriate to their particular trades.

Political activity by servicemen on behalf of a particular faction or cause would clearly be detrimental to the needs of discipline in an armed force. In general, there is an increasing tendency to allow soldiers far greater freedom during off-duty hours, so that life in barracks has come to resemble far more closely that of the civilian holding an "eight-till-five" job. There remains, however, the need for the military commander to exercise sufficient control over the private lives of his subordinates to ensure the efficiency, discipline, and good order of the force for which he is responsible. Any orders reasonably calculated to maintain these objectives are normally lawful, even though they may prohibit the soldier from some activity that may not be unlawful for a civilian. Few armed forces are, for example, prepared to retain practicing homosexuals in their ranks—not because of any moral disapproval but because the development of homosexual relationships within the closed community of a fighting force is all too likely to be subversive of discipline and effectiveness. For similar reasons—that is, the efficiency of the individual soldier and the force to which he belongs—the use of drugs is likely to be severely discountenanced.

(W.E.S./J.S.-Sm.)

Defense economics

OPPORTUNITIES FOREGONE: THE COST OF WAR

There is no such thing as an inexpensive war. First, there is the human cost in loss of life and in the physical and psychological maiming of healthy people. While the personal cost of such loss is immeasurable, the economic cost to society can be estimated. This measure was first proposed by a French economist, Jean-Baptiste Say, in 1803. He asserted the principle that war costs more than its direct expenses, for it also costs what its casualties (military and civilian) would have earned throughout their lifetimes if they had never participated in war.

Second, war has economic costs arising from the destruction of buildings, productive farmlands and forests, public services such as waterworks, electricity-generating and distribution systems, roads, bridges, harbours, and airfields, and all manner of personal and corporate property such as homes, possessions, factories, machinery, vehicles, and aircraft. War, therefore, destroys physical capital that has been created by previous economic activity.

Reconstruction after war is a particular economic burden because the finance, imported capital goods, and labour used in reconstruction merely restore the losses a country has sustained, rather than adding to the stock of capital available to its economy. Thus, even if it manages to restore all its physical losses, it uses scarce resources that would otherwise have been available for extending and improving economic activity. As most wars since 1945 have occurred in the Third World, some of the world's poorest countries have suffered the most from the economic losses of war.

War also costs a great deal in goods and services to create the weapons of war and to supply the people engaged in the war effort. The diversion of these goods and services—which range from the metals and chemicals transformed into weapons to the food, clothing, and shelter for the armed forces—reduces current civilian consumption, which lowers the population's living standards. Metal used to make a tank cannot be used to build bridges, fuel used to transport military supplies cannot be used on school buses, cement used to construct ammunition dumps cannot be used in house construction. This constitutes the opportunity cost of war—that is, the extent to which the economy foregoes the opportunity to commit these resources to alternative peaceful uses.

The opportunity cost of war is also felt in the future. In addition to allocating resources to consumption (the satisfaction of current needs), an economy allocates resources to investment (the new factories and machinery that produce tomorrow's goods and services). Resources diverted to war cannot be used to create new productive capacity for future consumption, and this reduces the living standards of the population below what they otherwise would have been in the future.

In summary, the total costs of war include the cost of the foregone use of the economic resources used up in the conflict. These include the cost of the foregone lifetime earnings of those killed in the war, the cost of lifetime medical care for those permanently incapacitated by the war, the cost of replacing the physical capital destroyed or damaged by the war, the cost of supplying the armed forces with the weapons of war, the cost of sustaining the armed forces and those in support functions (including their pay and pensions), and the losses to the economy caused by the diversion of resources from peaceful investment in future economic capacity.

DEFENSE EXPENDITURE: THE COST OF DETERRENCE

As war is expensive, countries aim to avoid its costs and remain independent within sovereign borders. In the absence of a universally binding and verifiable agreement to abolish war, the best option is to deter those countries prone, by their history or by the policies of their governments, to resolve disputes by resorting to war. Deterrence has two aspects. First, by allocating resources for a minimum level of military capability, a nation ensures that it can resist an attack by a potential aggressor and severely damage the aggressor's economy and territory. In this way the costs to the aggressor of initiating a war will far exceed any likely gains. Second, by making credible its willingness to use military force, should it prove necessary to do so, the nation aims to leave potential aggressors in no doubt of the consequences they will suffer if they are tempted to launch an attack.

Deterrence, while expensive, is incomparably less expensive than war. The study of its expense constitutes the subject matter of defense economics.

Measuring the burden. Adam Smith, the founder of economics as a discipline in the social sciences, was the first economist to theorize about the economics of war. In his major work, *An Inquiry into the Nature and Causes of the Wealth of Nations* (1776), Smith considered a perennial problem of defense management, namely, the increasing expense of war-fighting equipment. He noted that changing technology raised the costs of war—for example, that the musket was a more expensive item to acquire than its predecessor, the javelin. (In the same way, a modern jet fighter is much more expensive than its propeller-driven predecessor.)

The rising cost of weapon technology does not mean that defense costs (d) necessarily rise as a proportion of gross domestic product (GDP; the sum of all expenditures made in one year). The d/GDP ratio is a measure of the military burden, and evidence suggests that this burden has not risen through time (in high-income economies it has been falling for most of the post-World War II decades). Although the unit costs of specific weapons rise as technology adds to their capabilities, high-cost solutions to one form of a military threat (for example, the use of expensive tanks to defend against a massed tank attack)

[margin note:] Measuring social costs

[margin note:] The total costs

[margin note:] The d/GDP ratio

usually become vulnerable to low-cost alternatives (such as the relatively cheap antitank missile and precision-guided munitions), which either alter the nature of the threat or make redundant the high-cost solution.

In a developed economy, the annual costs of defense procurement and logistics typically take up more than half of the defense budget, the rest being spent on personnel. In the underdeveloped economies, the balance is reversed: most of the annual costs (70–90 percent) are spent on personnel, with the remainder spent on procurement and logistics. This difference reflects the gap in available warfighting technology between the developed and the underdeveloped worlds. The bulk of the world's defense spending is accounted for by the high-income economies (the United States, Europe, and the Soviet Union), primarily because of the cost of high-technology weapon systems. Yet most wars are fought in low-income countries between relatively poorly equipped armed forces. Moreover, the inability of low-income countries to maintain sophisticated weapons to the operational standards of their manufacturers fully explains the many logistical problems the armed forces of poor countries have faced in their wars. Importing sophisticated weapon systems does not guarantee a sophisticated defense capability if the support system (fuel, spares, ammunition, repairs, and overhaul procedures) is either less than satisfactory or less than adequately funded. Defense capability is inseparably linked to the cost of maintenance.

Defense is a public good; that is, once deterrence is achieved, all citizens benefit from the avoidance of war and no citizen can be excluded from enjoying the benefits. People who could not be excluded from a public benefit would, if given the choice, rationally choose not to contribute toward its cost. In other words, they could "free ride" on the contributions of others. For this reason, defense in all countries is paid for by taxation, a burden that is borne by all citizens, and in all countries the military force considered necessary for deterrence is under the direct and exclusive control of the government.

Comparing burdens. *Settling on a standard.* International comparisons of how governments arrange their defense spending are fraught with conceptual discrepancies. The defense burden of a country is measured by the d/GDP ratio, which indicates how much of the nation's resources are being allocated to defense each year, but different estimates of both d and GDP are possible, each giving a different d/GDP ratio. Capitalist economies, which use the GDP, measure economic activity differently from communist economies, which use a net material product (NMP) system. The NMP excludes many expenditures, including state administration and defense, normally included under GDP. This complicates comparisons between these systems.

Defense expenditures themselves are subject to controversy. The North Atlantic Treaty Organization (NATO) has agreed on a measure of defense activity to which it adheres when making comparisons of its members' defense burdens, but other countries follow different conventions. Some, largely low-income countries, exclude internal security expenditures, which can be relatively high, thus lowering their official d/GDP ratio. Others, such as the Soviet Union, exclude defense-related research and development, frontier guards, and paramilitary reserves, thereby reducing the nominal defense expenditure by up to 30 percent.

Even if agreement could be reached on what constitutes defense expenditure, this would still leave countries with a measure denominated in their domestic currencies. For meaningful comparisons of the absolute amounts spent on defense, every country's defense expenditures would have to be reduced to a common currency. But the act of converting each currency into, for example, U.S. dollars could lead to distortions, because official exchange rates reflect official policies and not existing realities. Thus, two countries with similar amounts in dollars spent on defense, and therefore in balance in their defense capabilities, could face a growing imbalance in their dollar-based defense expenditures purely because one of their currencies has changed its exchange rate with the U.S. dollar.

Comparisons of the absolute amounts each country

(margin note) Capitalist and communist measuring systems

spends on defense are prone to error and must always be used with caution. Nevertheless, because each country measures its defense spending and its GDP in its own currency, the d/GDP ratio is an acceptable measure of a country's defense burden. Ratios can be compared across countries and in different time periods. The d/GDP ratio rises rapidly during a major war—in Britain in 1944 the d/GDP ratio reached 60 percent—and it falls in periods of prolonged peace. A country raising its d/GDP ratio signals that it is concerned with security, in turn causing concern among countries likely to be affected.

Defense burdens worldwide. Security expenditures for both external defense and internal law and order account for major shares of government expenditures. In many low-income countries, these expenditures often exceed 20–30 percent of the state budget and more than 10 percent of the country's GDP. The higher-income countries, while spending higher absolute amounts on defense, tend to spend smaller proportions of state expenditure (under 15 percent) and smaller proportions of GDP (under 5 percent). Given the perilous security situation in the lower-income regions of the world, these discrepancies are understandable (if also regrettable in view of their other pressing needs).

(margin note) Defense spending in rich and poor countries

By looking at the actual defense burden of an individual country and comparing it with the norm for similar economies, analysts can infer localized circumstances that may be influencing the government's perceptions of security. For instance, a poor country with a very low d/GDP, or a rich country with a very high d/GDP, is behaving differently from the norm for similar economies. An economist would seek explanations for this in the perception of a threat indicated by the public statements of the government concerned. In the absence of such statements, or where public statements are contrary to the behaviour of the government (for example, if it is raising its d/GDP but publicly proclaiming its peaceful intentions and denying that it is threatened by, or is threatening, any other country), the economist would rely on the d/GDP as an indicator of true intentions. It is likely that the intelligence services of neighbouring countries would draw similar conclusions from the economic data.

Within the higher-income countries there are notable differences in the amounts spent on defense. The United States and Britain have spent relatively high proportions (5 to 10 percent) of their GDP on defense since 1955, compared with Japan, which has spent less than 1 percent of GDP over the same period. Germany and France also have tended to spend a smaller proportion of their GDPs than Britain on defense (though the absolute amounts have been similar, since they have larger GDPs than Britain).

The Japanese case is interesting because of the differences in economic achievement between Japan and the big defense spenders. Many economists believe that there is a connection between the amount of GDP spent on defense and a country's economic growth, investment, and living standards. Japan's limit of d/GDP to under 1 percent was a result of its defeat in World War II. There is no doubt that it benefited enormously from limited defense spending (particularly while it could free ride under the military protection of the United States), since resources not allocated to defense went into economic investment, to the direct benefit of civilian employment and output. However, at the same time Japan also spent much less (about half as much) of its GDP on general government expenditure (g) than the United States and western Europe. Whether it was the low d/GDP (1 percent) or the low g/GDP (9 percent) that allowed the resources for Japanese economic successes to be mobilized is arguable. A low g/GDP ratio implies a lower level of taxation than a high g/GDP. This releases a higher flow of savings into the economy, enabling higher investment ratios to be maintained. High rates of investment, which are associated with higher growth rates of GDP, characterized the Japanese post-war economy and are a more likely explanation for the Japanese economic success than its low d/GDP.

The Soviet Union has long spent a high proportion of its national resources on defense. Estimates vary, but the consensus among Western economists is that Soviet

(margin note) Effects of defense spending on economic growth

d/GDP for much of the postwar period was around 14 percent. (The official Soviet d/GDP was 6 percent.) If defense spending competes with economic growth in the capitalist economies, contributing to inflation, low investment, and lower living standards, then it must have a devastating impact on poorer economies such as the Soviet Union. The need to compete with the United States at all technological levels across the weapons spectrum has been met at the cost of heavy distortions in the rest of the Soviet economy. This has compelled the Soviet Union to review its priorities and to consider whether its security is best assured by continually raising the military ante with the West or by living at some lower level of military tension with a reduced offensive military capability.

DEFENSE MANAGEMENT: BUDGETING DETERRENCE

"How much defense is enough defense?" is the great unanswerable question of defense economics. Those charged with preparing a defense capability tend to be more cautious about the level of capability than those who eventually have to pay for it. In fact, the very success of deterrence—a high probability of nonattack throughout a long period of peace—tends to reduce the amount of defense spending that the electorate considers necessary to achieve deterrence. Judging the appropriate level of military preparedness is not a science; it is a mixture of intelligent response to credible threats and of judicious, cautious preparation "just in case" this or that should
Tension between managers and taxpayers arise. The managers of the armed forces tend to increase the contingencies they wish to prepare for, while skeptical taxpayers tend to question whether certain preparations are absolutely essential. In democracies this tension forms the permanent agenda of the defense debate.

Stocks and flows. Defense expenditures are made on an annual basis, the government allocating so much of its total budget to personnel costs, so much to the procurement of weapon systems, and so much to general support. The pay and allowances of defense personnel are consumed within the year; that is, they spend their wages, allowances, and pensions on consumer goods and, in so doing, add to total demand in the economy. Procurement, on the other hand, is somewhat different. A tank lasts much longer than the single year in which it is purchased. Because it is supposed to last as long as it takes to become obsolescent, the tank becomes part of the country's permanent defense capability. That defense capability is, in economic terms, a stock, while the annual expenditure is called a flow.

Even if, for some reason, a defense budget is reduced in a single year, a country's defense capability need not be reduced. The government can still draw on the stock paid for by previous defense budgets, which is manifested in its tanks, aircraft, ships, communications systems, trained personnel, and expertise in military affairs. Clearly, if the defense budget continues to be reduced every year, there will come a point at which the country's defense capability will decline through attrition as items of equipment become obsolete or beyond repair.

The analogy is with a bath that is filling with water while the plughole is open. As water pours into the bath, water also drains from the plughole. It is the difference between the rates at which water flows in and out that determines whether the bath fills or empties. If the flows in and out are equal, the water level will remain constant. Likewise with defense capability: if the additions (flow in) to the stock of weapons matches the attrition (flow out) of the stock from all causes, then the country's defense capability will remain constant.

Measuring a threat: the example of NATO. Budgeting a nation's defense capability is complicated, however, because defense capability is not determined unilaterally; it depends on the capability of the potential aggressor. The gap in military capability between any two countries is known as the threat, and estimates of the threat constitute the major input into defense planning.

If a potential aggressor develops an advanced weapon system that effectively counters a weapon stocked by the defender, it will eventually threaten to overwhelm the latter's defenses. Likewise, a growth in the stock of weapons deployed by a potential aggressor can eventually have a
similar effect in threatening to overwhelm the defender's smaller stocks. If the defending country does not invest in overcoming each new threat to its capability—by technology, new types of weapons, increasing the stock of current weapons, or all three options simultaneously—it will risk a reduction in the probability of nonattack—that is, its deterrence capability will be compromised.
Failing to invest in defense

The economics of nuclear deterrence. Estimates of the threat of a Soviet invasion across the German border determined the nature of NATO's response for more than 40 years. While NATO planners considered their own forces to be technologically superior to the Soviet forces, they were nevertheless mindful that the Soviet Union had a decisive quantitative superiority in conventional forces (more tanks, armoured vehicles, artillery, combat aircraft, and troops). The threat of a land-based invasion by Soviet forces, which the planners considered to be virtually unstoppable, led directly to the decision to deploy nuclear weapons as the ultimate deterrent against an invasion of western Europe.

Nobody could survive a major nuclear war in Europe. The damage to the Soviet Union from an American nuclear strike would be matched only by the damage to the United States from a Soviet nuclear strike. Because each country has maintained sufficient nuclear forces to respond in kind to a first strike by the other, a nuclear exchange would be suicidal for both. Whatever the rhetoric, therefore, both countries have a strong interest in preventing war of any kind from breaking out on the continent of Europe. Literally, they are hostage to each other's behaviour, making Europe an unsafe place to start a war. This doctrine, known as "mutual assured destruction," was given the appropriate acronym MAD.

The consequences of MAD led NATO to adopt a policy known as "flexible response." Rather than an all-or-nothing nuclear exchange, this envisaged a staged escalation of NATO's response to a Soviet invasion, based on containing the initial thrust of the Soviet forces and warning them of the consequences of further encroachment on NATO's territory. To underline the credibility of the threat of nuclear retaliation, NATO commanders were issued battlefield nuclear weapons, which NATO governments might or might not release for immediate use, with or without warning. Uncertainty about NATO's policy of probable first use of nuclear weapons was regarded as sufficient to make Europe an unsafe place for the Soviet Union to risk the consequences of a conventional war. As long as the risk of the horrendous consequences of a nuclear war exceeded the prospects of potential gain from launching an attack, the probability of nonattack on western Europe by the Soviet Union remained at an acceptable level.

The economics of conventional deterrence. The possession of nuclear weapons by some NATO countries (the United States, Britain, and France) did not obviate the need for expenditure on conventional armed forces. To abandon conventional forces would risk having to use nuclear weapons as soon as the first Soviet forces crossed the German border or some naval incident occurred in any part of the world. This escalation from a small incident to the end of the world in one short step was unacceptable; hence, NATO countries invested resources in conventional capabilities in addition to nuclear weapons. These conventional forces aim to blunt a Soviet attack and give time for political processes to influence the Soviet government's decisions.

Matching conventional forces to Soviet conventional capabilities had to take note of two facts: First, the Soviet Union had overwhelming superiority in conventional forces. Military doctrine holds that concentrating superior force at a single point can overwhelm the defense, and the Soviet Union had the capability to achieve such a strategic advantage at a time and place of its choosing. Second, while NATO had advantages in military technology, there was a constant effort by the Soviet Union to close the technological gap. Also, there is some point at which a quantitative advantage acquires a qualitative dimension, and this advantage cannot be neutralized solely by relying on a technological gap between the weapon systems themselves.

Closing the technological and quantitative gap

Thus the paradox of NATO defense spending. The alliance was constantly trying to widen the technological gap to compensate for its disadvantage in numbers, while at the same time it was required to maintain large quantities of its existing systems to redress the ever-widening gap in numbers that the Soviet Union was believed to be creating across the German border. Whether to develop ever-new weapon systems to combat a closing of the technological gap by the Soviet Union as well as the sheer numbers of Soviet systems, or to concentrate on supplying the armed forces with duplicate copies of existing designs, has long been NATO's quandary.

Choosing weapon systems. Since the 1960s there have been several attempts to impose some rationality upon defense planning. The complexity of weapons development has few parallels in civilian development. Working close to technological frontiers (sometimes having to think beyond them) under management systems imbued with a public-sector rather than a commercial ethos, under government budgetary constraints and shifting political priorities, and subject to ever-changing estimates of the threat the system is designed to counter, has produced an expensive and time-consuming procurement system. Lead times of 18 to 25 years from initial concept to in-service production are not unknown in defense procurement.

The need for more rational choices in weapon programs and in the deployment of scarce resources increased as the defense budgets grew in absolute size (though falling as a proportion of a growing GDP). The cost of errors in choice increases as the cost of a single weapon platform escalates, so that, with a new weapon system costing $10–40 billion, it is crucial not to find that it is not needed by the time it is in service, that the technology cannot be made to work, or that it has been made obsolete by new developments.

The Polaris submarine-launched ballistic missile program, begun by the United States in 1956, was the first highly complex system that required new management techniques to be brought to successful completion. One technique—called program evaluation and review technique (PERT)—found civilian applications after it was invented by the U.S. Navy to build Polaris on time and under budget. Similarly, earlier techniques such as cost–benefit analysis (invented to cope with submarine hunting problems during World War II) and input–output analysis (a technique developed by the U.S. Air Force for identifying the critical parts of an economy to develop or damage) rapidly spread into civilian use and into most academic management programs.

Rational economic choice of military options

The first attempts to bring rational choice to the management of a defense budget coincided with the U.S. involvement in Vietnam. Terms such as systems analysis, as well as planning, programming, and budgeting systems (PPBS) and functional costing, became common in defense management. Much of the intellectual capital invested in these techniques came from economists, whose discipline in costing options and marginal analysis provided them (if not always the defense managers they advised) a set of tools appropriate to the task.

When decisions are made solely by the lobbying of special interests—such as the navy, air force, and army—the result is likely to be a constant compromise under which programs remain in the budget because of political considerations. Defense analysts attempt to force the military lobbyists to set specific objectives for their programs and to accept criteria by which the military value of the programs can be judged. Like many management fashions, PPBS and its associated techniques did not survive in their earliest forms, but they did establish the belief that analyzing, evaluating, and choosing rationally was superior to lobbying by bureaucrats and, sometimes, by corrupting commercial interests.

This can be illustrated by the technique of functional costing. Ordinarily, most budgets are a listing of expenditures under various main headings—personnel, equipment, and supplies—and the total is approved through the political process. This type of budget is called an accountability budget because it accounts for defense expenditure, but it cannot inform the defense planner (or the taxpayer) how

efficiently the defense department has spent the budget. Under functional costing, the objectives of a proposed military program are shown along with the costs of all the resources needed to fulfill each objective, irrespective of which armed service contributes to the activity.

For example, under functional costing there is no navy budget that costs everything spent by the navy. There is instead a maritime defense budget, a deep-sea navy budget, a coastal defense budget, and so on. These budgets may include costed contributions from units of the navy, air force, and army, plus an assessment of the costs of support functions used to carry out the activities. If, for instance, it is proposed to add a longer-range aircraft to the maritime defense role, this can be costed, and, depending upon the importance of extending maritime defense compared to other objectives, an informed decision can be made on whether to allocate the incremental funds to the upgraded aircraft or to some other project supporting some other military activity. Deciding between marginal increases or decreases in expenditures across different functions, all of them linked to specified objectives, is an improvement over buying aircraft simply because it is the turn of the air force to get a big project approved by the government.

Conscript or volunteer. Modern armed forces use either a voluntary recruitment scheme or a form of conscription to supply the people needed to staff the military. Each scheme has economic consequences.

Conscription involves a period of compulsory military service for all eligible males, usually triggered by their date of birth. (In some countries, such as Israel, females are also required to undergo military service, though usually in a support rather than a combat role.) Conscription provides a pool of recruits at a low cost per head. The conscripts receive extremely low wages, well below what they would earn as civilians. This difference in earnings is a direct monetary loss to them and a loss to society, which loses the output they would produce if they remained civilians. Conscription offers a net saving only to the defense budget, although what is saved in personnel costs is largely spent in increased training costs. Conscript armies require much larger training programs than volunteer armies because the service life of a conscript (two or three years) is shorter than a volunteer's term of engagement (three to 15 years). Each new age group of conscripts has to be trained, diverting full-time soldiers from other duties as well as adding to overall costs.

Wages earned versus opportunities lost

Volunteer armies cost more per head because their wages must be comparable in some degree to civilian wages. While a national emergency can induce people to volunteer, a peacetime recruit is influenced by the alternative incomes that can be earned as a civilian. Some people volunteer whatever the wages, and some volunteer because they are unemployed as civilians, but most evidence indicates that volunteer rates will fall if military wages fall too far below civilian wages. This is particularly true for volunteer officers, who take with them critical skills when they leave the armed forces for well-paid jobs as civilians.

While volunteer armies cost more per head, they can cost less in total because they do not have to be as large as conscript armies. Although conscription is common across the three branches of the armed services, the proportion of regular volunteers to conscripts is smaller in the army and larger by far in the navy and air force. Ships and aircraft require more-skilled and better-educated personnel than infantry divisions, and the navy and air force in most countries tend to use conscripts only in less-skilled roles, reserving the command roles (pilots, captains, engineers, navigators) for volunteers. This pattern can be seen in many Latin-American military forces. In Israel, where conscription covers practically the entire population, the problem of retaining skilled recruits is met by extending the periods of military service through the civilian lifetimes of the recruits.

All personnel policies are vulnerable to demography. The proportion of a nation's population that is made up of young people eligible by fitness and intelligence for military service sets a limit on how many can be conscripted or induced to volunteer. Conscript armies, which are cost-effective when there is a large pool of young people from

The economics of conscription in rich countries

which to choose, are particularly threatened by demographic changes that reduce the pool of potential recruits. As the birth rate appears to fall in higher-income economies over time, the prospect for mass conscript armies looks bleak. Switching to an all-volunteer force is a short-term alternative, although the decline in the recruitable age group will force up military wages as the armed forces compete with civilian employers for the same age group. Substituting technology for labour is another short-term solution. But it too has limitations, not the least of them the problem of recruiting from a shrinking age group a sufficiently educated and skilled labour pool to operate sophisticated military equipment.

WAR FINANCE: WHEN DETERRENCE FAILS

War is too serious, and too expensive, to be left to the whim of chance, yet throughout history many governments have been willing to engage in war if it suited their interests as they perceived them, and many have also been dragged into wars when cooler calculations might have encouraged them to remain at peace. It was out of the need to raise the finance to conduct wars that the earliest systems for collecting public finance developed.

Taxation. The practice of taxing the population to pay for war has a long history. In early nomadic societies, wars could be fought with little expense other than time and casualties. Nomadic horsemen engaged in war as an extension of their normal activities as herdsmen. If successful, the warriors plundered the defeated, who were either killed, sold, or scattered. With more-settled agricultural societies, wars could be fought between planting and harvest, the armies living off the land or the pay of the king. In the feudal system each man had an obligation to fight if required by the lord of the manor, to whom the vassal owed his livelihood. Weapons were often the personal possessions of the warriors and were fashioned by themselves, their forebears, or craftsmen. As weapons improved in quality and ingenuity, special efforts to produce them had to be made—for which their producers were paid out of public funds, as were the soldiers to whom they were distributed. These expenses necessitated the collection of special funds, and thus the government turned to levies on the population to provide the resources.

Where taxation alone was not sufficient to pay for a war, the king could resort to selling relief from feudal obligations (usually to prosperous cities), and to borrowing from rich individuals (who risked confiscation if they refused and not being paid back if they agreed). Most political crises in European history up to the 19th century arose from disputes over public finance, usually to pay for wars. The English Civil Wars of 1642–51 were a typical example of a bitter dispute between king and parliament over which had the powers of taxation.

By the time of the French Revolution in 1789, warfare had ceased to be a localized affair with a few thousand soldiers engaged in a single decisive battle. Warfare had become a massive undertaking, often lasting months and years and involving armies of hundreds of thousands. The expense of war reached levels unheard of previously. The Royal Navy, for instance, employed 200,000 men in the 1790s alone. Out of the need to find new sources of revenue for the long war between Britain and France from 1793 to 1815, the British government introduced a temporary income tax to be levied on all persons earning above a high minimum income. The advantages of the system soon became evident, and income taxes were widely adopted as permanent sources of government revenue.

The income tax

Borrowing. The British government also discovered another source of revenue, the national debt. Whereas previous borrowings by monarchs were a great risk to the lender, under the national debt scheme the government agreed to guarantee regular payment of interest to all persons who lent to it, either in perpetuity or for a fixed term. Holders of government bonds were also permitted to sell them, passing the right to the guaranteed income to the buyer. Again, the system was so successful that it was soon copied by other governments, not all of them as scrupulous in their repayments as they promised. War bonds featured strongly in the two world wars, and it was regarded as patriotic to use personal savings to purchase them—though most of the borrowing came from institutions.

The new sources of war finance enabled the increased expense of war to be met—and, in the opinion of some economists, made it more likely that a government would embark on a war for less than good reason. If war had to be financed out of the current consumption of the population, natural limits would be set on war being undertaken lightly, but borrowing removed these limits. Though the population would be saddled with interest payments for decades to come, this cost was small and of long duration compared to the immediate cut in living standards that would have to be made to pay for a war in full.

War's consequences: inflation and recession. A major modern war can divert from 40 to 60 percent of a country's GDP, and one object of war finance is to release within the economy the resources needed for the war effort without causing inflation. If the government merely prints money to pay for the resources it requires, it will bid up prices in competition with civilians. The alternative is to reduce civilian consumption by imposing taxes at levels sufficient to force consumers to forego bidding for goods and services. The income from taxes can then be applied by the government to bid for the resources released by its program.

Taxation acts both to raise necessary finance and simultaneously to reduce aggregate demand, which releases the resources needed for the war effort. The war effort represents a substantial expansion of production, for which producers receive wages and profits. When these same producers attempt to spend their incomes, they face a diminished quantity of civilian goods available for purchase. They must either face rapidly rising prices (caused by excess money chasing insufficient goods), or they must restrain—or be restrained—from spending. A war economy therefore imposes higher taxes on wages and profits to reduce demand. War bonds and taxes provide finance for the war effort and reduce demand for civilian goods and services. To conduct a major war without such an austerity program risks inflation.

Reducing demand in wartime

If inflation is a risk during a war, recession is another risk at the end of it. The massive expansion in production to provide resources for the war effort, if suddenly contracted by the cancellation of all defense contracts, throws large numbers of people out of work. The unemployed reduce their consumer spending, causing further cuts in aggregate demand, which throws yet more people out of work.

World War I was followed by recession. Because much of the war damage along the Western Front was confined to the vast, static battlefields across France, where the destruction was mainly human and the cost was mainly in war materials, there was no need for a massive reconstruction program. Also, the damage on the Eastern Front was swept behind the newly formed Soviet state, which for ideological reasons eschewed capitalist reconstruction. After the war factories closed down, removing a flow of wages and profits into the economy, the demobilization of troops put surplus labour into an economy that was already in recession.

Recession was averted at the end of World War II by reconstruction of the cities and economies of western Europe and Japan. Reconstruction rapidly transformed the war economies into mass consumer economies supported by the pent-up demand that had been frustrated by the lack of civilian goods and by high taxes during the war. In Europe's case there was a transfer of capital from the United States through the Marshall Plan. As the war economies were dismantled, economic growth surged, and those countries that did best economically were those that dismantled their highly regulated, government-controlled war economies quickest (West Germany, for example). Those countries that were least successful in dismantling their regulated economies were the slowest to recover. Among these were Britain, which increased state intervention from 1946 to 1951, and the Soviet-controlled economies of eastern Europe, which went even further down the road of government-managed economies.

(G.Ke.)

THE CONDUCT OF WAR

Strategy

FUNDAMENTALS

Strategy, narrowly defined, means "the art of the general" (from the Greek *stratēgos*). In a strictly military sense, the term first gained currency at the end of the 18th century, when warfare was still relatively simple and limited. In its military aspect, the term had to do with stratagems by which a general sought to deceive an enemy, with plans he made for a campaign, and with the way he moved and disposed his forces in war. Often defined as the art of projecting and directing campaigns, military strategy came to preempt almost the whole field of generalship, short of the battlefield itself. It also came to include the planning of naval warfare. To tactics military jargon reserved the art of executing plans and handling forces in battle.

The expanding definition of strategy

The term strategy has expanded far beyond its original military meaning. As society and warfare have steadily grown more complex, military factors have become more and more inseparable from the nonmilitary in the conduct of war and in programs designed to secure peace. Nations have found it necessary to adjust and correlate political, economic, technological, and psychological factors, along with military elements, in the management of their national policies. The demarcation between strategy as a purely military phenomenon and national strategy of the broader variety became blurred in the 19th century, particularly in wartime. The distinction became even less clear in the 20th century when nations became more interdependent and the line between war and peace less clearly definable. As a result, the appearance of the term grand strategy (or higher strategy), meaning the art of employing all the resources of a nation or coalition of nations to achieve the objects of war (and peace), steadily became more popular in the literature of warfare and statecraft of the 20th century.

This broadened scope of strategy has tended to blur distinctions customarily drawn by earlier writers between strategy and statesmanship and between garden varieties and higher, or "grand," forms of strategy. Though there is still no agreed definition of the precise meaning of the term strategy, few students of the subject any longer accept the earlier narrow definition. Also, few contest that strategy, whether in its narrow or broad sense, will, by the very nature of its shifting bases, continue to be a changing art.

The search for principles. The starting point of all strategic planning and action is national policy. Once the national aims are set forth by the leaders of the state, the commander sets about drawing up his plans. He must take many matters into account; for example, factors of space and time, the state of his own forces, the enemy's capabilities and intentions, and reactions at home and abroad to his projected moves. The strategist deals in many uncertainties and imponderables. Indeed, the art of the strategist is the art of the "calculated risk."

The debate over the principles of strategy

The growing complexity of modern warfare has led some students to take a fresh look at the principles that have traditionally guided military strategists in war. It has long been a favourite occupation of military theorists to seek to distill from the great mass of military experience simple but all-pervasive truths—lists of principles—to guide commanders. Usually they have derived such principles from a study of campaigns of the great captains of history; occasionally outstanding practitioners have set them down on the basis of personal experience. As far back as 400 BC Sun-tzu, a Chinese general, set forth 13 principles. The axioms range from American Civil War General Nathan Bedford Forrest's simple admonition about getting there first with the most men to Napoleon's 115 maxims. The stress varies from list to list. For example, the followers and interpreters of the 19th-century theorist Carl von Clausewitz believed that the battle was all and that defeat of the enemy's armed forces was the correct objective and path to victory. Exponents of "the strategy of indirect approach," on the other hand, sought victory by indirect methods.

Though there is no complete agreement on the number of principles, most lists include the following: the objective, the offensive, cooperation (unity of command), mass (concentration), economy of force, maneuver, surprise, security, and simplicity. The British have added one called "administration"; the Soviets, another, translated as "annihilation." Despite debate over their precise number and meaning, the principles of war are widely taught, and most military students accept them as basic concepts.

The permanence or impermanence of strategic principles

The individual authors of the lists have almost uniformly claimed the principles to be immutable. They have argued that success in military strategy in the past has been the result of adhering to them and that the advantages of the offensive, the concentration of force, the effort to achieve surprise, the proper movement of forces, and their security from attack, sabotage, or subversion are in the province of modern as well as ancient warfare. Some authorities have even argued that since war is not the concern of soldiers only, the "principles" deserve a wider application throughout government—in grand as well as military strategy.

Other authorities have argued that the claim of immutability cannot be accepted literally, that there is little agreement as to what the principles are and mean, that they overlap, that they are fluid and require constant reexamination, that they are not comparable with scientific laws since no two military situations are ever completely alike, that the so-called principles are not really principles at all but merely methods and commonsense procedures adopted by great commanders of the past, and that changes in the conditions of war alter their relative importance.

The debate over principles was renewed with the coming of the nuclear era. Some theorists argued that the new weapons had destroyed whatever value the principles once had; others contended that the principles were as valid as ever, even more so. To some extent this was a debate over semantics. Defenders pointed out that each age must make its own applications of the "fundamental truths" of strategy. Opponents argued that there can be no set rules for the art; the so-called principles must by no means be interpreted as pat formulas for victory to be followed blindly and rigidly; the only sound guide in war and strategy is flexibility.

Relation between strategy and tactics. In the theory of warfare, strategy and tactics have generally been put into separate categories. The two fields have traditionally been defined in terms of different dimensions: strategy dealing with wide spaces, long periods of time, and large movements of forces, tactics dealing with the opposite. Strategy is usually understood to be the prelude to the battlefield, and tactics the action on the battlefield itself. As a result, much of the literature and theory of strategy has in the past been preoccupied with the proper approach to the battlefield, the leading of troops up to the time of contact with the enemy. This situation explains the attention to strategic maneuver—aimed at putting one's army into the most favourable position to engage the enemy and compelling the enemy to engage at a disadvantage and depriving him of freedom of movement. Indeed, early writers on strategy dealt heavily in the so-called "geometrical strategy"—the angles formed by lines of movement and supply of opposing armies.

Strategy as the prelude to battle

Despite distinctions in theory, strategy and tactics cannot always be separated in practice. In fact, the language of strategic maneuver (for example, "envelopment," "penetration," "encirclement") is also largely the language of tactics. Movement begets action, and action results in new movement. The one merges into the other. Strategy gives tactics its mission and wherewithal and seeks to reap the results. But tactics has also become an important conditioning factor of strategy, and as it changes, so does strategy. Battles and fronts are no longer necessarily restricted in space and time, and the distinction between battles and campaigns is no longer so clear-cut, as the tridimensional warfare of World Wars I and II demonstrated. Indeed, in World War II theatre commanders were as much con-

cerned with the actual fighting of armed forces in battle as they were with larger strategic decisions such as relations to allies, economic problems, and political questions on the ground. Although in theory strategy continues to occupy a middle ground between national policy and tactics, in practice the line dividing it from the other two fields has become difficult to draw.

Strategic leadership and war planning. Count Alfred von Schlieffen, the famous German military leader of the period just before World War I, once said: "A man is born, and not made, a strategist." But it is obvious that even a born strategist—if there be such a natural genius—has much to learn. In the past strategic leadership was a relatively simple affair. J.F.C. Fuller, the British student of warfare, pointed out in *The Foundations of the Science of War* (1926) that until relatively recent times the death, capture, or wounding of either of two opposing generals normally decided a conflict, "for the general *was* the plan." He could personally devise the plans and direct his troops. By the mid-20th century this was rarely possible. As warfare has become complicated, strategic leadership has become more difficult. The art has taken on many more facets, and systematic training is required to master them. The strategist has retired from the scene of battle, and large, specialized staffs have grown up to help him. Although the responsibility for strategy remains the general's, many of his functions have been delegated to his planning staff. In modern states corporate leadership has become the rule in the management of military strategy, as in the direction of large business enterprises.

The example of an Alexander the Great completing his advance planning and leaping into battle at the head of his troops would in modern warfare be considered most unusual. Napoleon was wont to make his plans and then retire with his retinue of trusted advisers to survey the battlefield on horseback from the top of a hill. Generals in World War I were often pictured in their offices in large headquarters—usually in a château behind the lines, studying a map on the desk and dispatching orders via the telephone and motorcar at hand. In World War II the headquarters staffs of commanders in the theatres of war grew even larger and more elaborate. Tridimensional warfare—land, sea, and air—had enlarged the field of operations far beyond individual battlefields, and usually a high commander reached his decisions in a headquarters far removed from the field of battle and months before the battle itself took place. Far from striking the classic pose of the officer on a well-schooled charger, some of the greatest generals issued their orders from desks and fought their most important battles at conference tables. As strategic planning became a highly organized affair, planning committees and conferences in the capital cities of the warring powers made the blueprints for victory in the global, coalition struggle. In their capital command posts, military leaders kept in touch with the manifold phases of the national government's war effort and dealt with the worldwide problems transcending those of the individual theatres of war. With the aid of new devices for rapid communication, these leaders and their staffs sought to set the patterns of strategy and keep abreast of the movement of armies as the Caesars and Napoleons had done in earlier eras.

As war became more total, war planning became a significant peacetime function of governments. The manufacture of strategic plans has become a highly specialized industry in modern military establishments. At the same time, more and more governmental agencies have been drawn into the business of planning for national security. The plans they produce may vary from a simple design to shift a small task force to a danger spot to an elaborate plan for the conduct of war in its entirety. To be realistic, strategic plans and estimates must constantly be reexamined and brought into harmony.

Against this general background in the nature of the art, it is now possible to sketch the important contributions made in key periods to modern strategic theory and practice. It is important to remember that the art of strategy has changed from age to age, just as has war itself, and that each is the product of its own society and time.

"Corporate" leadership in modern strategy

Strategic planning as a peacetime function

HISTORICAL DEVELOPMENT THROUGH WORLD WAR II

Though the serious and systematic study of modern strategy may be dated from the 18th century, various authorities have identified strategic precedents going back to earliest times. Students of warfare of primitive ages have associated with primitive tribes and clans a stratagem of surprise from darkness or by ambush, and they have identified a strategy of hunt and pounce, like that of a lion or tiger. The Bible points to the care with which Moses prepared his operations—an early form of advance planning. The ancient world developed a strategy of mass attack by phalanx, legion, or cavalry. Alexander, Hannibal, and Caesar, who combined in their own persons political and military direction of the state, planned their famous campaigns far ahead. They have been singled out as forerunners of the modern art of grand strategy. Writers in modern times have used the campaigns of these great captains to illustrate practically every known "principle of war." But important as their attention to strategic considerations in war and especially to strategic approaches to the battlefield may have been, the foundations of the ancient art of warfare were tactics and battles. To a considerable extent battles—often short and furious—also held the centre of the military stage in the European Middle Ages. Strategy was notably absent in the excursions of the Huns, the Muslims, and the crusaders. Far more important from a strategic viewpoint were the campaigns of Genghis Khan and his general, Sabutai, in the 13th century. Their advance planning and bold strategic maneuvers in broad sweeps from Mongolia across Asia and Europe showed an appreciation of strategic problems most unusual for their age.

In the transition to modern times two other figures who touched on the field of strategy are often mentioned—Niccolò Machiavelli in the realm of military thought and Gustav II Adolf in the field of generalship. Machiavelli's *Art of War* (1520) emphasized the larger aspects of war, particularly the close relationship between the civil and military spheres. A century later, Gustav, ruler-general of Sweden, intervened in the Thirty Years' War and, maneuvering skillfully, drove his enemy's armies out of northern Germany.

18th-century warfare. After the death of Gustav Adolf in 1632, warfare again settled down to a slower pace and a more stable mold. The 17th and 18th centuries experienced the growth of professional armies loyal to the king. But the great cost of building and maintaining such armies led to a concern for their safety, a hesitation to risk them in bloody encounters, and a preoccupation with defense and fortifications. Strategy during this period was essentially of limited aim and was greatly concerned with the art of siegecraft, for which elaborate rules were prescribed. In Prussia of the mid-18th century, however, circumstances compelled Frederick the Great to try a new and aggressive approach and to break through the accepted military pattern of the day.

Confronted at the outset of the Seven Years' War (1756–63) by a coalition of Austria, France, Russia, Sweden, and Saxony, Frederick found himself virtually surrounded. His task was to devise a strategy to defend his territory and not to dissipate his outnumbered troops. The strategy he evolved did not follow set rules or recipes. Indeed, never was the definition of strategy as a "system of makeshifts"—offered in a later age by the Prussian general Count Helmuth von Moltke—better demonstrated. In his planning Frederick capitalized on two valuable assets—his army, a superior and highly disciplined instrument of war, and a central position. He sought always to keep the initiative, to attack first one enemy and then another, to assemble at decisive points a force superior to that of his foe, and to avoid long, drawn-out wars. Using his central position to concentrate against individual armies of the enemy before they could be reinforced by others, he developed the classical "strategy of interior lines." But even Frederick, the statesman-warrior, could not entirely escape the conditions imposed by the warfare of his times. Indeed, the statesman imposed caution on the warrior. He could not expose his costly armies to the risk of destruction and bloody decision by battle. His battles were not those of

[margin notes right column:]
The absence of strategy in ancient warfare

The aggressive, flexible strategies of Frederick the Great

annihilation. In the end his wars were decided by reasons of state, and those wars left his nation exhausted.

The age that immediately followed Frederick chose to imitate his caution rather than his aim. Military theory was characterized by ideas of victory without battle, maneuvering for position, a system of lines and angles of operation. Geometric concepts and cunning tricks and artifices replaced the aim to destroy enemies. Great emphasis was put on terrain and the occupation of key geographic points. The 18th century, it must be remembered, was the era of enlightenment, and warfare conformed to the spirit of the age. Strategy, like all warfare, became "mathematical" and "scientific." Theorists optimistically maintained that a general who knew mathematics and topography could direct campaigns with geometric precision and win wars without even fighting. But the new mode of warfare ushered in by the French Revolution and the Napoleonic era was soon to challenge these optimistic assumptions.

Napoleonic warfare. The French Revolutionary and the Napoleonic periods (1789–1815) witnessed great changes in the methods of war—the revolution in society accompanying and reinforcing the one in warfare. When Napoleon, the first great military strategist of the modern Western world, burst upon the European scene, the groundwork for a new age in warfare had already been laid. The French Revolution gave birth (1793) to the "nation in arms," and all Frenchmen became liable for military service. The patriotic citizen-soldier succeeded the mercenary professional. Skirmish tactics, or the loose formation, replaced the straight line; divisional organization came into use, along with lightweight artillery of great range and firing power. When Napoleon came to reap the benefits of these changes, he completely transformed strategy as well as tactics. He applied the same basic principle to the one as to the other—never to divide his forces but to concentrate all his might against the enemy forces at the critical point. His emphasis was on careful preparation, on uniting his forces before the action, on overpowering weight of striking power, on shock attack, on great daring, and on bloody decision by battle. His methods were simple, direct, overpowering—even brutal; his aim was nothing short of the destruction of the enemy forces. Against such power, neat geometric calculations stood little chance and ordinary stratagems were helpless. Again and again he showed his military genius for bringing a mass to bear against the flanks of his enemy, for selection of battle-grounds advantageous to his forces, and for deploying his forces for battle. He gave supreme expression to the idea of victory by battle.

Though as a military leader, operational strategist, and tactician of the battlefield Napoleon is regarded by many as unparalleled, in the larger field of national or grand strategy he had shortcomings. Embodying in his own person the leadership of the state and its military affairs, he recognized the value of incorporating political and economic measures, along with military moves, to increase the chances of victory in war. But he could not successfully grasp and cope with the challenge finally put to him by Great Britain and its European allies. British strategy sought to meet the Napoleonic threat to Europe by using naval power to blockade the Continent and by conducting a war of exhaustion on land through peripheral warfare, such as the Duke of Wellington's famous campaign on the Iberian Peninsula. Napoleon's reply to the British naval blockade was the continental system prohibiting British goods from entering. But this helped bring his downfall, since he was needed everywhere—to hold the coast and to fight in Spain, in Holland, and against Austria and Russia. His veteran French forces were dissipated, and he had to rely on impressed nationalities of Europe. Eventually the coalition of his enemies was to use the methods and means of warfare that the French Revolution had introduced and Napoleon had perfected to reinvigorate their own forces and overwhelm him.

Despite his mistakes, Napoleon's preeminent place in the history of strategy is secure. His tactics and strategy influenced military leaders for a century. His maxims were widely studied and were said to have been carried in the saddlebag of the famous Confederate general of the

The strategy of maneuver and position

The overwhelming concentration of force

The protracted war of exhaustion

American Civil War, Thomas J. ("Stonewall") Jackson. Students of strategy have long pointed to Napoleon's battles and campaigns for classical illustrations of "principles" of war—of surprise, mobility, concentration of force, and economy of force. Possibly more than that of any other general, his competent practice oriented modern military theory toward the search for underlying principles. Indeed, the art of strategy as evolved by theorists since 1800 may be traced largely to his operations. For this development two great interpreters of Napoleonic strategy, Antoine-Henri Jomini and Carl von Clausewitz, were especially responsible.

Carl von Clausewitz.   Clausewitz (1780–1831), a Prussian, was the first great student of strategy and the father of modern strategical study. He was trained in systematic study of philosophy in the school of Immanuel Kant, thus it was natural for him to range widely over the whole field of military knowledge and to reduce Napoleonic warfare to a unified philosophical conception. His famous work *On War,* written as an outgrowth of his studies of Napoleon's campaigns, remains the best general study of the art of war. He died with his work unfinished, but his writings published after his death became the standard textbooks on war in Prussia and elsewhere. Their influence was felt profoundly in the Franco-German War of 1870–71, and leading generals of World Wars I and II were brought up on them and on the works of his followers.

The contributions of Clausewitz to strategic thought are many and diverse. To some his work is the Bible of strategy, and, like that great book, susceptible to many conflicting interpretations. His work set forth fully and clearly for the first time the relationship between political and military leadership. He dwelt on decision by battle as the first rule of war, on seeking the destruction of the enemy's forces, and on achieving superiority at the decisive spot. Rejecting the optimism and rationalism of the 18th century, he held that war was not a scientific game but an act of violence. Mathematical and topographical factors, he held, were important in tactics but less so in strategy. "We . . . do not hesitate," he asserted, "to regard as an established truth that in strategy more depends on the number and the magnitude of the victorious combats than on the form of the great lines by which they are connected." The key to victory was battle, however bloody. He defined strategy as the employment of battles to gain the end of war.

Clausewitz devoted much of his work to showing that war is both a social development and a political act. He went further and said that "war is not merely a political act, but also a real political instrument, a continuation of policy carried out by other means." War was therefore not an independent phenomenon unto itself to be handed over to soldiers and sailors. Again and again he asserted that military and political strategy must go hand in hand. "War," he declared, "admittedly has its own grammar, but not its own logic."

Clausewitz' emphasis on the aim of strategy as the destruction of the enemy's forces on the battlefield has had a great influence on subsequent military thinking. His disciples, however, have generally overlooked the fact that he also recognized another strategical form—a strategy of limited aim for limited warfare, of wearing down an opponent. When Clausewitz wrote, warfare was conducted in two dimensions, and it was rarely possible for one nation to impose its will without first destroying the opposing army. But Clausewitz recognized clearly what many of his followers in subsequent generations forgot, that the destruction was only a means to enforce policy and not an end in itself.

Antoine Jomini.   In the history of military thought, the French general Antoine-Henri Jomini (1779–1869), one of Napoleon's staff officers and a contemporary of Clausewitz, presents a striking contrast to the Prussian philosopher of war. Lacking the philosophical bent of Clausewitz, Jomini concentrated his thinking on what he regarded as practical issues in war rather than on war as a whole. He became the chief expounder of Napoleonic methods, and out of his studies evolved a theory of strategy. Although he opposed "systems of war" purporting to provide for

Victory through destruction of the enemy's forces

all contingencies, he nevertheless believed that in the field of strategy certain rules and general principles—eternally true—could and should be formulated "as a compass for the commander-in-chief of an army." To establish these principles, he believed, was the major problem of military science.

Victory through the occupation of territory

The heart of Jomini's theory lay in the theatre of war and the campaign. But he thought primarily of occupying all or part of the enemy's territory rather than of annihilating his army. This occupation was to be achieved by progressive domination of zones of territory. Jomini emphasized throughout his work the proper choice by the general of decisive maneuvering lines and their adaptation to geometric configurations of zones of operation. Campaigns must be carefully planned in advance. The task of strategy is to make preliminary plans—to establish lines of operation and to bring military means into conformity with geographic realities of the chosen zone of operations. He laid down two basic principles: massing troops against fractions of the enemy by rapid movement and striking in the most decisive direction.

Jomini's great contribution to military thought lay in his definition of the place of strategy in warfare. Probably more than any other work, his *Summary of the Art of War* (1838; *Précis de l'art de la guerre*) fixed the major fields of modern military art. Subsequent wars were to cast doubt on much of his work, particularly on his conception of geographic campaigns and of the superiority of interior lines of operation. But, like Clausewitz in German strategic thinking, Jomini had an enduring influence on French military thought. His emphasis on planning for operations and on intelligence took root in military staffs and schools throughout Europe, and his work became the textbook for the conduct of the American Civil War.

American Civil War to World War I. Often called the first of the really modern wars, the American Civil War (1861–65) marked a transition to a new era in strategy. It gathered up new phenomena that had begun to influence warfare in the middle of the 19th century and whose fuller consequences were to be felt in the half century that followed. It was a period marked by refinement of the old in strategic theory and practice and by the addition of new strands—by such famous figures as Robert E. Lee, Ulysses S. Grant, and William T. Sherman on the battlefield and Count von Moltke, Count von Schlieffen, Hans Delbrück, and Alfred T. Mahan in the literature of strategy.

Strategies of North and South. The Civil War is significant in the history of strategy in a number of ways. The

The growing speed and scale of warfare

basis of strategy—particularly factors of time and space—began to change. The use of steam power for land and water military transportation received its first major test. Railroads gave strategy a new speed of movement but tended to make strategy stick to straight lines and fixed routes. The Civil War also tested ironclad ships and heavy naval ordnance. The relation among the combat arms was completely upset by the introduction of the long-range infantry rifle. The accuracy of long-range weapons in the hands of defending infantry shattered the effectiveness of the rapidly concentrated attack in which Napoleonic strategy had culminated. But, as so often has been noted in the history of warfare, armaments and weapons are more readily changed than ideas, and Napoleon's principles continued to be maintained, sometimes with disastrous consequences on the battlefield.

Aside from the effect of new inventions, the Civil War revealed the growing importance of the economy and manpower in war. Industry was called on more and more, and conscription was adopted to provide manpower. The war also revealed the impact of systematic West Point training received by the leading generals on both sides. Finally, the Civil War was long studied for classic examples of maneuver and of offensive and defensive strategy and for lessons in the relation among policy, strategy, and means of war. Essentially the Civil War demonstrated local or theatre strategy and tactics. Though elements of grand strategy were at hand—political, economic, military, and psychological—the art was still not well understood or consistently applied. Despite conscription and the partial mobilization of industry and the railroads, there was no

well-worked-out grand design correlating the widely scattered forces and the war industries that supported them.

The strategies of the North and South were rooted in different political objectives. The objective of the North was to prevent the Confederate states from seceding from the Union, that of the South was to attain independence. Because the South was greatly inferior to the North in population and resources, it could not hope to conquer the North. The dual purposes of its strategy were to convince the North that forcing the South to remain in the Union was not worth the cost and to bring about foreign intervention in favour of the South. General Robert E. Lee, the great Southern leader, believed the best way to realize these objectives was to carry the war into the North and to defeat the Northern armies in their own territory. For a time, therefore, his strategy was essentially offensive. But after his defeat at Gettysburg, Pa., he no longer had the wherewithal to continue the offensive, and at the same time it became obvious that foreign intervention would not be forthcoming. From that time to the end of the war his strategy was defensive, with the object of wearing down the patience, if not the power, of the North.

Effects of political objectives on strategy

To achieve its political object, the North, on the other hand, developed another strategy. The Federal design had three main goals: (1) to blockade and isolate the Confederacy, (2) to cut it in two, and (3) to strike at Richmond, Va., its capital. The naval blockade, though not completely effective, brought virtual commercial isolation to the South. Partition was gained by capturing Vicksburg on the Mississippi in July 1863 and by severing the east–west railroad connections. The capture of Vicksburg cut the South off from its sources of supplies beyond the Mississippi. Only gradually did the North change its design from that of attacking Richmond to that of striking at the main army of the Confederacy and the remaining sources of supply. Grant's elevation to the supreme command of the armies in March 1864 enabled him to put this concept into effect. The famous march of General Sherman through Georgia to the sea in the fall of 1864 was an outstanding example of strategic maneuver and surprise. Leaving his supply line, Sherman feinted against one city and attacked another, finally cutting off Lee's army in Virginia from its war resources in the South. The cooperation of the Federal eastern and western armies in a grand converging movement resulted in the evacuation of Richmond and, finally, in the surrender of Lee's arms to Grant at Appomattox Court House in Virginia in April 1865.

The period from the close of the Civil War to the outbreak of World War I saw the further growth of trends already apparent. Space and time factors began to appear in a new light. A nation with a well-developed railway net gained significant advantages in war. The speed of mobilizing and concentrating armies became a basic element in strategic calculations, and the timetable based on it became the heart of staff plans drawn up in anticipation of war. Increased firepower in the machine gun, universal liability of able-bodied males for military service, rapid mobilization of reserve military units, and increased potential of fortifications influenced military planning.

The Prussian-German strategists. Strategic thinking in the half century before World War I showed a remarkable diversity. To the Prussian-German school—Moltke and Schlieffen—the new trends in warfare seemed to reinforce Clausewitz' teachings about battles and the aim of defeating the enemy's armies.

To Field Marshal Count Helmuth von Moltke (1800–91) belongs the chief credit for molding the Prussian army into a formidable war machine, which defeated the Danes (1864), Austrians (1866), and French (1870–71). Moltke agreed with Clausewitz that battles were the primary means of breaking the will of the enemy. But Moltke did not believe a strategist could follow a rigid set of rules. To him strategy was a system of "ad hoc expedients." It was "the art of action under the pressure of the most difficult conditions." No plan of operations, he believed, could look with any assurance beyond the first encounter with the main enemy forces. The offensive, according to Moltke, is "the straight way to the goal," whereas the defensive is "the long way around." He became famous

Moltke's emphasis on offense and "ad hoc expedients"

for his skillful conduct of operations on the outer line leading to encirclement. In addition to exploiting the altered conditions of space and time created by the railroads and improved highways, he capitalized on the possibilities offered by the telegraph for handling armies of great size. Recognizing that the field of operations had become too vast to be surveyed by the eye of the commander, he introduced a new system of delegating power to subordinate commanders. Broad directives took the place of detailed orders. Moltke always fought with superior forces, and his wars, culminating in that against France in 1870–71, are regarded by some authorities as classical models of conception and execution in military strategy.

Schlieffen's "strategy of annihilation"

Field Marshal Count Alfred von Schlieffen (1833–1913), chief of the Prussian general staff before World War I and ablest of Moltke's successors, carried the strong line of strategic reasoning running from Napoleon through Clausewitz and Moltke to its logical conclusion in his conception of a "strategy of annihilation." Like Moltke, he stressed the military side of strategy, the concentration on decisive victory by battle. But, unlike Moltke, he could not count on superior forces and had to prepare for war on two fronts. The basis for German strategy before World War I as developed by him was embodied in the famous Schlieffen plan. The plan was extremely simple. The bulk of the German forces were to attack the nearest opponent, the one in the west (France), and to defeat him in a great battle; meanwhile, in the east (Russia) the Germans would stand on the defensive. Schlieffen proposed to gain the decision in the great battle by means of an enveloping attack—if possible, by a double envelopment. Once the enemy in the west was defeated, the Germans would attack the foe in the east. This was the essence of the plan with which the Germans entered World War I.

Schlieffen's theories were to have wide influence, largely through his book *Cannae*. Analyzing Hannibal's great victory over the Romans in 216 BC, he had developed his theory of the battle of annihilation by means of encirclement and double envelopment. The decisive German campaign against the Russians at Tannenberg, East Prussia, in August 1914 was fought in this mold, and Schlieffen's theories were studied exhaustively in the higher army schools of the United States and Europe after World War I. As General Walter Bedell Smith, chief of staff to General Dwight D. Eisenhower, supreme commander of the Allied Expeditionary Force in World War II, pointed out, General Eisenhower and many of his staff officers, products of these schools, "were imbued with the idea of this type of wide, bold maneuver for decisive results."

Political-military strategy: Delbrück and Mahan. Moltke and Schlieffen thought of war as military action—the speediest decisive defeat of the main opponent. But the closing years of the 19th and early years of the 20th centuries witnessed the emergence of new approaches and different emphases in strategy. Two thinkers looking to past history for light on the problems of their times made signal contributions to strategic theory—one, Alfred Thayer Mahan (1840–1914), an American, in the field of naval strategy, the other, Hans Delbrück (1848–1929), a German, in the area of military strategy. Each recognized an intimate relationship between war and politics in every age, that political and military (or naval) strategy must be in harmony. Each showed an awareness of the growing importance of the economic bases of strategy, of state policy, geographic position, and available means as determinants of the mode of strategy, and of accommodating strategic action to suit the particular times and needs.

Delbrück's "strategy of exhaustion"

Carrying forward a line of thinking already suggested by Clausewitz, Delbrück presented his theory of the "strategy of exhaustion"—of wearing down an opponent by a variety of means. Clausewitz had merely indicated the existence of two methods of conducting war—one aimed at annihilation of the enemy, the other limited warfare. Delbrück expounded on the differences. The sole aim of the strategy of annihilation he identified as the decisive battle. The second type he called variously the "strategy of exhaustion" and "two-pole strategy." The commander could move between battle and maneuver; the political object of war could be obtained by other means than

battle—by occupying territory, blockade, destroying crops or commerce. In Delbrück's view, Alexander, Caesar, and Napoleon had been strategists of annihilation; Pericles, Gustav II Adolf, and Frederick the Great, equally great generals, exponents of the strategy of exhaustion. Holding that the strategy of exhaustion was just as valid as the strategy of annihilation—each depending on the political aims and means at hand—Delbrück's theories ran counter to the military thinking of his day and brought down a storm of criticism about his head. But he persisted in reminding his age, intent on victory by battle, of other important and forgotten aspects of Clausewitz' teachings.

While Delbrück was battling his military critics in Germany, a scholarly navy captain and teacher at the Naval War College in Newport, R.I., was quietly breaking ground in pursuing his brilliant researches in military and naval history and strategy. This pioneer was Alfred Thayer Mahan, indefatigable student of the strategy of Napoleon and Jomini. His masterly works, *The Influence of Sea Power upon History, 1660–1783* (published in 1890) and *The Influence of Sea Power upon the French Revolution and Empire, 1793–1812* (published in 1892), marked a revolution in naval thought. While advances in technology were affecting naval architecture and weapons, and steam, armour plate, and rifled guns were coming into vogue, Mahan aimed to bring naval strategic thinking up to date. The books and articles that poured from his pen down to World War I about warfare of the second dimension—the sea—had a profound influence on the theory of warfare and on naval policy and strategy in many countries.

An advocate of a big navy, of overseas bases, of national greatness through sea power, he was the American apostle of "looking outward." Mahan emphasized the significance of commerce in war and of economic warfare through the application of sea power. His researches convinced him that the nation or group of nations that commanded the seas could best draw on the trade, wealth, and economic resources of the world and was the more likely to win wars. Strongly influenced by Jomini's teachings, he looked for fundamental truths and formulated "principles" of naval strategy. Naval strategy and sea power, he recognized, were conditioned by a nation's insular or continental situation. To Mahan, a central position gave the same great advantages on the sea or on land—interior lines. Concentration of force he viewed as a fundamental principle of land and sea warfare. The backbone of fleet strength, in his opinion, was the battleship or capital ship. Under Mahan's tutelage, the twin theories of coastal defense and commerce raiding, which hitherto held sway in American naval strategy, gave way to the theory of command of the sea. Command of the sea can be defined as that condition under which friendly ships can use the sea freely but under which an enemy, though venturing out to sea, cannot do so with any security. Mahan's concepts of naval strategy and faith in preponderant naval power and the use of the navy as an instrument of national power were accepted by the U.S. Navy and President Theodore Roosevelt. His doctrines stimulated the trend toward overseas expansion and growth of the navies of the world between 1898 and 1914. The sudden acquisition of an overseas empire in the Spanish-American War of 1898 greatly changed the strategic position and problems of the United States. Its emergence as a world power, beginning in these years, was to have important bearings on the strategic balance of power among the nations of the world, an equilibrium that World War I altered profoundly.

Mahan's command of the sea

World War I. *The war.* World War I, the first of the great coalition wars of the 20th century, was an important landmark in the story of the evolution of modern strategy. Never was the phenomenon of cultural lag as applied to warfare more clearly demonstrated. Beginning in the accepted mold of strategic planning popular since 1870, it soon ran head on into countertrends that were altering the very bases of strategic action and that strategic thinking in the intervening years had not yet fully grasped. Despite the experiences in the South African and Russo-Japanese wars with the machine gun as a defensive weapon of tremendous firepower, French and German military leaders at the outbreak of the war continued to put their faith in the

The failure of mass offensives

offensive. In fact, they were convinced that new weapons and methods of control, the radio and telephone, actually improved the offensive capabilities of their mass armies. The universal underestimation of the effect of modern firearms on the defense had important repercussions on strategy both during and after the war.

The first moves in the war began in 1914 as French and German strategists had planned. In seven days the Germans concentrated more than three million men on the eastern and western fronts from mobilization points. In approximately the same time the French assembled 1.2 million men on the western front. Both sides made heavy use of railroad lines to speed assembly of great masses of troops. Both sides were determined to attack. Out of the movements of mass armies came the first battles on the frontiers. As Schlieffen had planned, the Germans catapulted into Belgium, but the enveloping wing was not as strong as Schlieffen, who had died the previous year, had wished. It was compressed into a smaller corridor by the political decision not to violate Dutch neutrality. The anticipated six-week campaign of annihilation against France envisaged by Schlieffen could not be executed. The French attack also soon hit a snag. Although the French army's right wing reached the Rhine, its centre was endangered by a German pincer movement. Only a hasty retreat and a counteroffensive at the Marne River saved Paris. "Pinwheel strategy"—each side attacking and driving the enemy back—had stalled badly.

Meanwhile, on the eastern front, the German prewar strategy of holding until France had been quickly defeated was compromised by the desire of the Austrian ally to push against the Russians, partners of the French. The German victory at Tannenberg counterbalanced the Austrian defeat at Lemberg (Lvov). The eastern front became stabilized.

By the close of 1914 the war had become a stalemate on both the eastern and western fronts. The conflict had resolved itself into trench warfare from Switzerland to the English Channel. Machine guns and artillery took over the battlefield. The conflict had settled down into a war of position, and strategic mobility was lost. World War I became a classic case of arrested strategy.

Break-ing the defensive line   The first phase of the war was over by the end of 1914. Prewar plans had failed; the war of movement, of mass offensives, had ceased. The big question thenceforth was how to dig the war out of the trenches. In answering that question important elements of grand strategy came into play. The heavy demands upon industry for munitions of war multiplied, and technology was called upon for new means—the tank and poison gas—of breaking the stalemate. Britain's naval blockade to starve Germany took on added significance. The German countermeasures helped bring the United States into the war in 1917. The United States was not prepared for war, however, and the buildup of its forces across the Atlantic was slow. The Germans, seeking in 1918 to forestall the full impact of U.S. might, put their resources into a great offensive that came close to succeeding. When the Americans finally arrived in force, they played a valuable part in military strategy in reducing the salients within the Allied lines. Eventually the German allies were defeated; the German armies reached a point of exhaustion and the homeland a stage of semistarvation. Germany asked for an armistice.

The lessons. Although much has been written about World War I, the strategic lessons of that conflict for coalition warfare have not been fully comprehended. Never was the dependence of strategy on statecraft more clearly demonstrated. As political circumstances of the war changed, strategy changed. The Central Powers, led by Germany and Austria-Hungary, never had a common plan of campaign or effective unity of command. The Allied side achieved unity only under necessity. Along with the military factors, economic and psychological consider-ations proved important in conducting the war and gain-ing victory. Although the aim of annihilating the enemy was paramount with both sides—especially in the open-ing campaigns—the desire to exhaust him also influenced strategy, and fresh confirmation was given to Moltke's description of strategy as a "system of makeshifts."

Military leaders in World War I had to master three basic factors in strategic calculations: masses of men, tech-nological advances, and wide areas. The movement of huge masses became an art in itself, for armies had taken on unprecedented dimensions. Millions of men were in action. Railroads and motor transport became important not only for concentrations but also for establishing new strategic points on the fronts themselves. The arena of war embraced whole continents. Battles lasted for days and weeks, and the fighting continued even after the great battles were over.   **The conduct of mass warfare**

New weapons came into play. Aerial reconnaissance en-abled a commander to gain some insight into the enemy's intentions and movements. New means of communica-tion—telephone, radio telegraphy, the automobile, and the airplane—promoted faster execution of orders and unified command over widely scattered forces. The overwhelming firepower of modern weapons checked the effectiveness of the attack, long considered the ideal path to victory. The tank, however, offered fresh possibilities in redressing the balance between the defensive and the offensive. Tactics became more than ever a prelude and conditioning factor of strategy, since without freedom of movement, strategy was only an academic exercise. Tactics came to mark the beginning rather than the conclusion of an operation.

There were also larger strategic influences at work. If World War I was a war of masses, it was also a war of matériel. War was becoming increasingly total and cut deeper into the life of the nation. Some of the foremost leaders and students of World War I—notably Winston Churchill and Georges Clemenceau—recognized that mil-itary strategy had become but a part of a greater national strategy. Symptomatic of this thinking was Clemenceau's widely quoted statement that war was too important a business to be left to soldiers. More than ever strategy and politics would have to be correlated. The increasing totality of modern war would have to be matched by a broader national strategy. The large impact of the war in the international sphere—the effects of the defeat of Germany, the weakening of England and France, the rise of the Soviet Union on the strategic balance of power in the world—could not yet be foreseen.

Between World Wars I and II. The period between 1918 and 1939 saw strategy once more in process of flux. As an outgrowth of the experience of World War I, strat-egy came largely to mean defense. In France, particularly, a mentality favouring fixed defenses began to take hold, eventually leading to the building of the concrete fortifica-tions of the Maginot Line, bordering Germany. The belief was strong that field fortifications aided by the machine gun would contain any attack. The huge losses of World War I would thereby be avoided.

Douhet: air supremacy. Countertrends, however, were soon to dispute this prevalent emphasis in strategic think-ing. One strong challenge came from the new school of exponents of air power. In World War I the air arm had had its beginnings. The period between the end of World War I and the beginning of World War II saw it come into its own; air forces and air organization expanded greatly. Theorists began to develop the strategy of warfare of the third dimension. Foremost among these was the Italian general Giulio Douhet (1869–1930). He first pre-sented the doctrine that the air arm alone would decide wars of the future. In his view, land and sea forces would no longer be decisive. On the ground, armies could act henceforth only on the defensive, since attack, and with it the decision, could be gained only through the air. Air power could quickly conquer time and space. The air arm could circumvent every kind of ground resistance and nullify fortified positions and obstacles of terrain. It could strike at the enemy's sources of power before his armies could fire a shot. It could strike at his capital, industrial centres, and communications. In short, it could so reduce his ability and willingness to resist that he would surren-der. Douhet proposed to expand the air arm as much as possible, keep land and sea forces only as support for war in the air, and gain control of the air by defeating enemy air forces in battles or destroying them in their airfields. He made strategic bombing and the industrial objective—   **The neutral-ization of land and sea forces**

strikes at the opponent's heart—the core of his doctrines.

Douhet's epoch-making ideas found many supporters in other countries. This school of thought generally argued that huge armies would no longer be necessary. The opponent's will could be overcome even if his armed forces remain undefeated. Some of Douhet's adherents went further and demanded the abolition of land and sea forces altogether. In any event, the rise of air power accentuated the need of thinking of strategy as dealing with something more than the movements of armies on land or of ships at sea.

Fuller: mechanized armour.   Meanwhile, army leaders began to advocate another solution to break the strategic stalemate of World War I. To overcome the superiority of the defensive, they put their faith in developing a modern cavalry of tanks and armoured, motor-driven vehicles. The best known among the great champions of mechanization and motorization that arose in Great Britain was Major General J.F.C. Fuller (1878–1966). These advocates saw in the armoured vehicle, combining firepower, extreme mobility, and armoured protection, the best answer to overcoming defensive forces relying on machine guns. This system was particularly suited to needs of an insular country, protected by a strong air force and navy, and of a relatively small army intended primarily for expeditionary purposes in support of continental allies. But this solution on the ground found support in Germany, the Soviet Union, and the United States. In France, Charles de Gaulle bucked the strong tide of opinion and advocated tank warfare to restore a strategy of mobility and the offensive.

In the late 1930s the Germans combined air power and tanks into a new form of assault that also aimed to overthrow defensive superiority. Developing a highly mobile form of warfare for lightning strikes and mechanized attacks, they were to contribute the art of the blitzkrieg—the spearhead of a conquering, offensive strategy that Hitler unleashed in World War II.

Ludendorff: total war.   In Germany, too, other influences supporting offensive strategy came to the fore. To overcome strategic stalemate of the World War I variety, the German general Erich Ludendorff contributed his theory of total war. He envisaged total mobilization of a nation's human power and resources for war. The nation at war would be led by a supreme military commander; strategy would dictate policy. The concept of total war moved geography and economics into prominent positions in Nazi thinking. Even before World War I the British geographer Halford J. Mackinder had posed the potential threat of a heartland power, in control of Eurasia, to sea power—a counter to Mahan's theory of control of the seas. The German geopoliticians after the war took over the "heartlands" concept, and through their teachings the concept of control of Eurasia became embedded in Nazi statecraft. Their doctrines gave support to the main strands in Hitler's offensive strategy—continental expansion, autarky (national economic self-sufficiency), and *Lebensraum* ("living space").

Before war burst upon Europe in 1939, it was apparent that important changes also were brewing in naval strategy. All major sea powers were producing high-speed battleships, and the aircraft carrier was becoming a significant and integral member of the fleet. In the crucible of World War II, the emerging elements in ground, air, naval, and nonmilitary strategy were to take clearer shape.   (Ma.M.)

World War II.   *The first phase.* In spite of the ideas of military reformers such as Douhet and Fuller, the lesson derived from World War I by orthodox strategists throughout Europe was that war between industrial societies would involve the total mobilization of all national resources and would be a test as much of economic strength and civilian morale as of military skills.

Germany was no exception. Hitler's military advisers warned him that the Third Reich, which had begun to rearm only in 1934, would not be ready to confront France and Britain until 1941 at the earliest. Hitler in September 1939 ignored this advice. He recognized that his adversaries were even less ready for war than he was, and he had, in the combination of infantry, armour, and air support developed by elite units of the Wehrmacht, an ideal instrument for his immediate objective of overrunning Poland. It proved equally successful when turned against the West in May 1940. Hitler's panzer divisions broke through the French defenses at the Ardennes and cut the Allied armies in two. The forces to the north had to be evacuated over the beaches of Dunkirk with the loss of all of their heavy equipment. A week later the Germans attacked the demoralized remainder of the French armies to the south, and on June 16 the French government asked for terms. Germany accepted the surrender of nearly two million French prisoners and had lost only 50,000 men.

The French defeat had been as much moral as military. The people had faced the prospect of war with dread and had accepted with relief the assurance of their military leaders that World War I had proved the invincibility of the defensive. The "Maginot mentality" had little to do with the Maginot Line itself—that system of fortifications along France's eastern frontier that was designed quite properly to economize on personnel and that the Germans never attacked. Rather, the French military leadership simply could not believe in the possibility of open warfare and therefore had provided their forces with neither the equipment nor the training nor the communications to undertake it.

The British had relied on France to provide the main land forces while they were to deploy their traditional strength at sea and contribute a long-range bomber force to attack German industrial strength at the source. But the Royal Air Force (RAF) in 1939 had neither the range nor the equipment nor the capacity to attack the German homeland in the necessary strength, and it was to take three years for its raids to have any serious effect. The RAF came into its own in a defensive role in the summer of 1940 when Hitler launched his Luftwaffe to obtain command of the air over Britain as a preliminary to a seaborne invasion. Britain had made a massive investment in radar early-warning systems and fast-climbing fighters, and these aircraft, fighting over their own territory, just turned the scale in what became known as the Battle of Britain. Hitler postponed the invasion and decided instead to neutralize Britain by submarine blockade and air bombardment while he prepared to attack the Soviet Union.

If Hitler was to achieve his long-term objective of a self-sufficient Third Reich controlling the grainfields of the Ukraine and the oil of the Caucasus, he had to destroy the Soviet Union sooner or later. His decision to do so sooner was probably precipitated by his need for those resources if he was to defeat a Britain sustained by all the resources of a United States—which, although at this stage determined to keep out of the war, was equally determined not to see Britain lose. Further, Hitler and his military advisers held Russian military capability in contempt. The incompetence of the Red Army had been shown when, in the Russo-Finnish War of 1939–40, it had taken three months to break the resistance of the small state of Finland. The directive for attack was issued on Dec. 18, 1940, and the attack launched on June 22, 1941.

At first all went as expected. German armoured divisions, driving deep in a series of encircling attacks, had by the beginning of December occupied 900,000 square miles (2,340,000 square kilometres) of Soviet territory, taken three million prisoners, and reached the suburbs of Moscow. But the Soviet leadership was prepared for such setbacks. Soviet prewar military doctrine had stressed total mobilization of the population, elasticity in operations, and defense in depth. Soviet war industries lay behind the Ural Mountains, beyond Hitler's reach. Reserve forces were switched from the Far East and counterattacked north of Moscow on Dec. 5, 1941. Two days later Japan attacked the U.S. Pacific Fleet at Pearl Harbor, and the war became global.

Global war.   Japan had been gradually expanding its power on the Asian mainland since the beginning of the century and had been at war with China since 1937. In 1940 the defeat of France, Britain, and The Netherlands in Europe exposed their possessions in Southeast Asia to attack. Japan's military leaders resolved to seize them so as to establish an autarkic empire immune to the eco-

Complete mobilization of resources

The "Maginot mentality"

Japan's strategy of expansion

nomic sanctions by which the United States was attempting to check their expansion into China. The attack at Pearl Harbor was a preemptive strike to gain command of the western Pacific. Simultaneously, Japanese forces attacked the Philippines, Malaya, and the Dutch East Indies. The British fortress of Singapore capitulated with 130,000 troops to a Japanese force 15,000 strong on Feb. 15, 1942. An American garrison held out at Corregidor in the Philippines until May, but within three months of launching their attack the Japanese had gained all of their immediate objectives.

The United States thus found itself at war, alongside two hard-pressed allies, with two triumphant military empires that were still expanding their power. Germany, checked through the winter, opened a powerful offensive in the spring of 1942 toward the Caucasus. In June, Japan launched a further drive toward the U.S. bases in Hawaii. This was foiled on June 5 by the decisive Battle of Midway, which not only established U.S. command of the seas but confirmed the role of the aircraft carrier as the new "capital ship" of naval warfare. By the end of 1942 Germany and Japan had expanded to the limit of their capacity. At the long Battle of Stalingrad (August 1942–February 1943), German offensive power was broken by Soviet armies as decisively as the Japanese had been by the U.S. Navy at Midway. The Allies were now able to mobilize and deploy an overwhelming superiority of resources. But German and Japanese defensive strength was still intact, and German submarines prevented the full deployment of Allied strength until the spring of 1943.

British and American war leaders agreed that defeat of Germany should be given first priority—a decision accepted with reluctance by the U.S. Navy, whose prewar planning had been directed primarily against Japan. But whereas the U.S. strategy for a European war was simple—accumulation of a large force in Britain in 1942, a cross-Channel attack and decisive battle in France in 1943—the British urged an initial concentration in the Mediterranean, where their troops had been fighting in North Africa since 1940, in order to knock Hitler's ally Italy out of the war and divert German forces from the Russian front. Both agreed, however, on a combined bombing offensive against Germany, and by 1944, in spite of German countermeasures, Allied bomber forces were inflicting lethal damage on the German economy. A series of compromises resulted in Allied landings in French North Africa in November 1942, in Sicily and Italy in 1943, and finally a cross-Channel attack in 1944, just as the victorious Soviet armies were advancing into eastern Europe. Invaded from east and west, its cities destroyed from the air, Germany capitulated on May 8, 1945.

Although Britain fought a successful campaign to recapture Burma (Myanmar), and the Soviet Union participated in the last days of the war, the direction of the war against Japan was the exclusive concern of the United States. The U.S. Army favoured a land-based approach via New Guinea and the Philippines to mainland China, whence a major invasion could be launched against the Japanese homeland. The Navy pressed for a direct advance via the islands of the central Pacific, so as to blockade and starve out Japan. Resources were in fact available for both strategies. With complete command of the sea, U.S. forces had by March 1945 captured island bases from which their heavy bombers could destroy Japanese cities one by one. The atomic bombs dropped on Hiroshima and Nagasaki on Aug. 6 and 9, 1945, were only the coup de grace in this process of destruction.

Victory of superior resources
The orthodox prewar strategists were proved correct: World War II was indeed eventually won by the mobilization of superior resources, ruthlessly and often wastefully employed against militarily more skillful foes. The use of nuclear weapons signaled both the consummation and the transformation of total war.   (M.E.Ho.)

STRATEGY IN THE NUCLEAR AGE

Strategic thinking after World War II, at least with regard to conflict between the great powers, was dominated by two related developments. The first was nuclear weapons, which raised the prospect of war as the ultimate catas-

trophe. This led to a shift of focus in strategic thinking toward the deterrence of war rather than the waging and winning of war.

The second development was a decades-long continuity in the East–West conflict, with two alliances each dominated by a superpower—the North Atlantic Treaty Organization (NATO) by the United States and the Warsaw Pact by the Soviet Union. Although attempts to reproduce these alliances in continents other than Europe met with scant success, their stability within Europe meant that they were virtually taken for granted. Therefore, there was less postwar interest in the issues of alliance formation and disintegration, which had preoccupied earlier generations of strategists.

The atomic bomb and American strategic thought. The first successful test of the atomic bomb took place in New Mexico in July 1945, as the leaders of Britain, the Soviet Union, and the United States met at the Potsdam Conference to discuss the shape of the postwar world. This context coloured the early American appreciation of the potential foreign-policy role of the new weapons, with the result that nuclear strategy thereafter became bound up with the twists and turns of the Cold War between East and West.

However, the decision actually to use the bomb against Japan reflected the more immediate urge to end the war as soon as possible and certainly before it became necessary to mount an invasion of the mainland. The atomic bombing of Hiroshima and Nagasaki in August 1945 was a means of shocking Japan into surrender. The choice of civilian rather than purely military targets, and the consequent immense loss of life, reflected the brutalizing experience of the massive air raids that had become commonplace during the war. Afterward it was assumed that any future atomic bombing would also be against cities. As weapons of terror, they appeared to have brought 20th-century trends in warfare to their logical conclusion.

Weapons of terror

The first nuclear weapons were in the range of other munitions (the bomb that destroyed Hiroshima was equivalent to the load of some 200 B-29 bombers); also, at least initially, the weapons were scarce. The key development introduced by atomic bombs was less in the scale of their destructive power than in their efficiency. By the start of the 1950s, though, this situation had been transformed by two related developments. The first was the breaking of the U.S. monopoly by the Soviet Union, which conducted its first atomic bomb test in August 1949. Once two could play the nuclear game, the rules had to be changed. Anyone who thought of initiating nuclear war would henceforth need to consider the possibility of retaliation.

The second development followed from the first. In an effort to extend its effective nuclear superiority, the United States produced thermonuclear bombs, based on the principles of nuclear fusion rather than fission, upon which the atomic bombs were based. This made possible weapons with no obvious limits to their destructive potential. Opposition to this development by influential nuclear scientists, such as Robert Oppenheimer, was disregarded by President Harry S. Truman on the grounds that the Soviet Union would not suffer from any comparable moral inhibitions.

This move was not matched by a pronounced nuclear bias in U.S. strategy. The weapons were still scarce, and it seemed only a matter of time before whatever advantages accruing to the United States through its lead would be neutralized as the Soviet Union caught up. The Truman administration assumed that the introduction of thermonuclear weapons would extend the time available to the United States and its allies (including NATO) to build up conventional forces to match those of the Soviet Union and its satellites. A series of events, from the Berlin blockade of 1948 to the Korean War of 1950–53, had convinced the United States that the communists were prepared to use military means to pursue their political ambitions and that this could be countered only by a major program of Western rearmament.

Endurance of conventional strategy

Massive retaliation. The administration of President Dwight D. Eisenhower, which came to power in January 1953, saw things differently. It reflected on the frustrating

experience of the inconclusive conventional war fought in Korea and wondered why the West had not made more of its nuclear superiority. Eisenhower was also extremely worried about the economic burden of conventional rearmament. Assigning a greater priority to nuclear weapons provided the opportunity to scale down expensive conventional forces. By this time the nuclear arsenal was becoming more plentiful and more powerful.

The strategy that emerged from these considerations became known as "massive retaliation," following a speech made by U.S. secretary of state John Foster Dulles in January 1954, when he declared that in the future a U.S. response to aggression would be "at places and with means of our own choosing." This doctrine was interpreted as threatening nuclear attack against targets in the Soviet Union and China in response to conventional aggression anywhere in the world.

Massive retaliation was widely criticized. In the United States the Democratic Party, whose policy under Truman was being reversed—and the army and navy, whose budgets were being cut at the expense of the air force's Strategic Air Command—charged that it placed undue reliance on nuclear threats, which would become less credible as Soviet nuclear strength grew. If a limited challenge developed anywhere around the Sino-Soviet periphery (the two communist giants were seen to constitute a virtual monolith), and the United States neglected its own conventional forces, then a choice would have to be faced between "suicide or surrender."

First and second strikes. Massive retaliation was also criticized for failing to appreciate possible areas of Soviet superiority. This criticism grew after the Soviet Union demonstrated its technological prowess by successfully launching the first artificial Earth satellite (Sputnik 1) in October 1957, not long after it had also made the first tests of an intercontinental ballistic missile (ICBM), the SS-6. Concern grew that the Soviet Union was outpacing the United States in missile production, so leading to a "missile gap." (It might have been argued that after a certain level of destructive capability had been reached by both sides, an effective stalemate would be reached and extra weapons would make little difference, promising only, as British prime minister Winston Churchill put it, to make "the rubble bounce.")

However, by this time nuclear strategy was becoming much more sophisticated. With the RAND Corporation, a think tank based in Santa Monica, Calif., taking the lead, new analytical techniques were being developed. These were often drawn from engineering and economics, rather than the more traditional strategic disciplines of history and politics. In a celebrated RAND study of the mid-1950s, a team led by Albert Wohlstetter demonstrated that the air bases of the Strategic Air Command could be vulnerable to a surprise attack, after which retaliation would be impossible, thereby exposing the United States and its allies to Soviet blackmail.

A devastating surprise attack was considered possible because, with improved guidance systems, nuclear weapons were becoming more precise. Therefore, it was not in-
Counter-
value and
counter-
force
strikes
evitable that they would be used solely in "counter-value" strikes against easily targeted political and economic centres; instead it was just as likely that they would be used in "counterforce" strikes against military targets. A successful counterforce attack that rendered retaliation impossible—known as a "first strike"—would be strategically decisive. If, however, the attacked nation possessed sufficient forces to survive an attempted first strike with retaliatory weapons intact, then it would have what became known as a second-strike capability.

Other strategists, such as Thomas Schelling, warned that if both sides sought a first-strike capability, this could lead to an extremely unstable situation, especially during a period of high political tension when both were nervous as to the other's intentions. If it were feared that an enemy first strike was imminent, then there would be powerful pressures to attack first, and if the enemy recognized these pressures, then that would encourage him to get in his strike. Schelling described this as the "reciprocal fear of surprise attack."

On the other hand, if both sides were confident of their second-strike capabilities, then there would be considerable stability, as there would be no premium attached to unleashing nuclear hostilities. The benefits of a mutual second-strike capability led to the concept of arms control, by which potential adversaries would put less priority on simply lowering their force levels (as advocated by proponents of disarmament) and more on removing incentives to take the military initiative in the event of a severe crisis.

Mutual assured destruction. In the event, technological developments supported the second strike. Initially, long-range bombers had to be kept on continual alert to prevent them from being eliminated in a surprise attack. When ICBMs moved into full production in the early 1960s with such systems as the U.S. Titan and Minuteman I and the Soviet SS-7 and SS-8, they were placed in hardened underground silos, so that an unlikely direct hit would be required to destroy them. Even less vulnerable were submarine-launched ballistic missiles (SLBMs) such as the U.S. Polaris and the Soviet SS-N-5 and SS-N-6, which could take full advantage of the ocean expanses to hide from enemy attack.

Meanwhile, attempts to develop effective defenses against nuclear attack proved futile. The standards for antiaircraft defense in the nuclear age had to be much higher than for conventional air raids, since any penetration of the defensive screen would threaten the defender with catastrophe. Progress was made using surface-to-air missiles (SAMs), such as the U.S. Nike series, in developing defenses against bombers, but the move to ICBMs, with their minimal warning time before impact, appeared to render the defensive task hopeless. Then, during the 1960s, advances in radars and long-range SAMs promised a breakthrough in antiballistic missile defense, but by the early 1970s these in turn were countered by improvements in offensive missiles—notably multiple independently targeted reentry vehicles (MIRVs), which could swamp any defenses. (The first MIRVed ICBMs were the U.S. Minuteman III and the Soviet SS-17.)
The futility
of anti-
nuclear
defense

Measures of civil defense, which could offer little protection to the civilian populace against nuclear explosions and, at best, only some chance of avoiding exposure to nuclear fallout, also appeared hopeless in the face of the overwhelming destructive power being accumulated by both sides.

By the mid-1960s fears had eased of a technological arms race that might encourage either side to unleash a surprise attack. For the foreseeable future each side could eliminate the other as a modern industrial state. Robert McNamara, the U.S. secretary of defense for much of that decade, argued that so long as the two superpowers had confidence in their capacity for mutual assured destruction—an ability to impose "unacceptable damage" defined as 25 percent of population and 50 percent of industry—the relationship between the two would be stable.

The need to maintain strategic stability influenced the strategic arms limitation talks (SALT), which began in 1969 and became the centrepiece of President Richard M. Nixon's policy of détente with the Soviet Union. In 1972, with the ABM Treaty, the two sides agreed to ban nationwide antiballistic missile systems, thereby confirming the primacy of the offense. Attempts to consolidate the strategic standoff with a treaty limiting offensive weapons proved more difficult. (In 1972 only an interim freeze had been agreed.) The second round of talks was guided mainly by the concept of parity, by which a broad equality in destructive power would be confirmed. However, the difficulty in comparing the two nuclear arsenals, which differed in important respects, resulted in long and complex negotiations. A treaty called SALT II was agreed on in June 1979, but by this time détente was in decline, and it was dealt a final blow with the Soviet intervention in Afghanistan at the end of that year. In addition, the strategic underpinnings of arms control had been undermined by a growing dissatisfaction in the United States with the principles of mutual assured destruction.

Alternatives to assured destruction. Critics found the condition of mutual assured destruction—which had become known by its acronym MAD—alarming. If MAD

failed to deter, then any war would soon lead to genocide. In addition, if the threat of retaliating with nuclear weapons was used to deter only nuclear attack, then the value of nuclear threats in deterring conventional aggression would be lost. In principle, this could undermine the commitments made to allies to use nuclear weapons on their behalf if they faced such aggression.

Particularly alarming was evidence that the nuclear strategy of the Soviet Union envisaged using nuclear weapons in a traditional military manner much as if they were conventional weapons—that is, at most to obtain a decisive military advantage in a conflict and at the very least to reduce the damage that an enemy might do to Soviet territory (if necessary, by launching preemptive strikes). During the negotiations that led to SALT II, critics also argued that the momentum behind the Soviet ICBM program, in combination with improved guidance systems that gave unprecedented accuracy to MIRVed missiles, had opened a "window of vulnerability" in the U.S. deterrent force. They expressed concern that the Soviet Union, by deploying the SS-17, SS-18, and SS-19 ICBMs, was building a force of such size and accuracy that just a portion of it could attack and destroy the U.S. Minuteman and Titan ICBM force without killing huge numbers of civilians. Although this would not be a true first strike, since U.S. bombers and submarines could retaliate, these latter delivery systems were not accurate enough to produce an equivalent counterforce attack against Soviet missile silos. Instead, the United States would be forced to escalate the war by retaliating against cities. This repugnant act would be of no strategic value, however, because the rest of the untouched Soviet missile force would then be used to wipe out U.S. cities. The United States, therefore, would have placed itself in a position in which it would have to choose between surrender and slaughter.

The realism of this scenario may be doubted, given that no attack against U.S. ICBMs would be accurate enough to avoid massive civilian destruction; therefore, the Soviet Union could be certain that the United States would feel little repugnance at retaliating against Soviet cities. Nonetheless, it was used to criticize SALT II, a complicated treaty that offered few means of verification and did little to interfere with the Soviet ICBM program. It was also used to argue for the development of U.S. ICBMs comparable to the Soviet systems.

The first formal break with assured destruction came in 1974, when Secretary of Defense James Schlesinger announced that future U.S. nuclear targeting would be geared to selective strikes and not just the sort of massive attacks suggested by the philosophy of mutual assured destruction. Although President Jimmy Carter's secretary of defense, Harold Brown, was skeptical that either side would actually find such sophisticated nuclear strikes possible, he accepted the need to develop a range of targeting options to convince the Soviet Union that it could not gain the upper hand by such methods. This was the main theme of the "countervailing" strategy announced in 1980.

Ronald W. Reagan came to office the next year with a much more radical critique of MAD, and his presidency was devoted to attempts to escape from its constraints. Initially, this took the form of a search for offensive nuclear operations that would enable the United States to "prevail" in a protracted war with the Soviet Union, rather than just countervail. It involved upgrading the old civil-defense systems and deploying the MX, an experimental ICBM originally designed to survive a first strike through some form of mobile deployment. Neither of these ideas was politically popular. In the end, civil defense was rejected as impossible, and the MX (now named Peace-keeper) was deployed in Minuteman silos and in only a fraction of the originally proposed numbers.

In March 1983 Reagan announced the start of a second search for a means to escape from MAD. This time it was for a defensive system that could intercept ballistic missiles. Reagan spoke of his preference for protecting lives rather than avenging them, and of the possibility of rendering nuclear weapons "impotent and obsolete," but the vision could not be turned into reality. Although the Strategic Defense Initiative, or SDI (which critics dubbed

Star Wars, after a science fiction movie), was given a high priority and billions of dollars for research, the idea of protecting society as a whole from nuclear attack soon appeared hopelessly impractical, given the diverse means of delivering nuclear weapons. The main question became whether SDI could protect key political and military assets from attack, but even here some of the more futuristic ideas—such as using space-based lasers to destroy ballistic missiles just as they were launched—proved technically demanding and expensive. Political support waned.

Meanwhile, Reagan had replaced talks on arms limitation with the Strategic Arms Reduction Talks (START). At first the Soviet Union argued that no progress on strategic arms control was possible so long as SDI was being pursued. Mikhail Gorbachev, who became the Soviet leader in 1985, offered his own vision of how to escape from assured destruction in a speech of January 1986, in which he set out a radical disarmament agenda leading toward a nuclear-free world by the end of the century. In October 1986, at a summit in Reykjavík, Ice., Reagan came close to embracing this vision, although no agreement was reached because he refused Gorbachev's demand to abandon SDI. Nevertheless, the concept of arms reduction had taken hold, and START proceeded with a new emphasis on deep cuts in nuclear arsenals.

The switch to arms reduction suggested that Reagan's critique of MAD had concluded with the view that, given the difficulties of designing and deploying both discriminating offensive options and effective ballistic missile defenses, it was better to do away with nuclear weapons altogether. This constituted a formidable challenge to the orthodox view that nuclear weapons exercised a stabilizing deterrence on international misbehaviour and were a reassurance to America's allies, who faced preponderant Soviet conventional forces. Reagan was prevailed upon to moderate his critique, but not before doubts had been created as to the strength of the U.S. commitment to guarantee the security of its allies with nuclear weapons.

On the other hand, the alacrity with which Gorbachev embraced complete nuclear disarmament reflected the greater freedom of maneuver available to any Soviet leader as well as the subordinate role of the Warsaw Pact allies. Whereas NATO's European members were anxious to lock the United States into their security arrangements for fear that they would be unable to stand alone, the Soviet Union had drawn its allies into a pact that met its own security requirements—that is, extending its form of government into eastern Europe and creating a buffer between it and the hostile capitalist forces of the West. Members of the Warsaw Pact might be beneficiaries of a Soviet nuclear guarantee, but there was no question of shared decision-making on nuclear matters. In fact, during the 1970s Soviet doctrine had appeared to have the goal of extracting the maximum regional benefit from its nuclear arsenal—vis-à-vis both western Europe and China—while maintaining Soviet territory as a sanctuary from nuclear devastation. Its priority in any nuclear conflict would have been to confine nuclear exchanges to central Europe, while showing a certain respect for U.S. territory as a sanctuary in the hope of reciprocal treatment by the United States. If escalation had appeared inevitable, however, or if the United States had appeared to be preparing a first strike, then Soviet doctrine would have called for a preemptive blow against the United States' long-range arsenal in an effort to reduce damage to the Soviet Union.

This approach was undermined by evidence that U.S. nuclear doctrine and deployment showed no respect for geographic sanctuary and by the Soviets' own recognition of the sheer difficulty of managing a nuclear exchange in such a way as to reduce the vulnerability of Soviet territory. Even before Gorbachev, there had been a discernible trend in military thinking toward emphasizing the opening conventional stage of a war and toward achieving victory within that stage. Gorbachev accelerated this trend. Because he was not prepared to allow overambitious nuclear doctrines to interfere with his objective of improving relations with the West, he was much more prepared than his predecessors to compromise in arms control negotiations. In addition, he was influenced by the April 1986

disaster at the Chernobyl nuclear power plant, which demonstrated that radioactive fallout had little respect for national boundaries.

Flexible response.   This gave a new twist to the long-standing debate within NATO over nuclear deterrence. The United States' allies had already learned to live with unavoidable doubts over the quality of the U.S. nuclear guarantee of European security. These began to surface in the 1950s, after the Eisenhower administration had embraced nuclear deterrence and the allies had agreed that it was natural to rely on the most advanced weapons available—especially those in which the United States then enjoyed a clear superiority. The alternative course—relying on conventional forces—would have caused severe economic strains, and there was deep pessimism as to the possibility of ever matching Soviet conventional strength.

The conventional buildup set in motion came under the Truman administration had one important requirement: that the Federal Republic of Germany be rearmed. This set in motion a sharp debate in Europe that was coloured by memories of the recent war, but in 1955 a formula was found in which West Germany rearmed but was permitted no chemical or nuclear weapons and was part of NATO's military command. In return, the West German government sought a commitment by its new allies to the concept of forward defense, in which any aggression would be rebuffed at the border between East and West Germany. (With its lack of depth and its concentration of population and industry close to the East, the Federal Republic had no wish for its allies to trade German soil for more time in responding to a Soviet attack.)

Once it was decided that NATO would not attempt to match Soviet conventional forces, then forward defense meant, in effect, that nuclear deterrence was linked to the inter-German border. European members of NATO had no qualms with this arrangement, because it saved them the expense of sustaining large-scale conventional forces, and they did not believe that the Soviet Union had any interest in invading western Europe that would be worth the slightest risk of nuclear war.

In the early 1960s the administration of President John F. Kennedy, which confronted the Soviet Union over the Berlin Wall and the Cuban missile crisis, did not take such a relaxed view of Soviet intentions. Given what it | The threshold between conventional and nuclear war | saw as the Soviet capacity for retaliation, the United States thought it unlikely that any president would use nuclear weapons first, and it was hard to see how a credible deterrent could be fashioned out of an incredible nuclear threat. At the very least, the United States insisted, NATO should raise the nuclear threshold, that is, the point at which nuclear weapons would be necessary to stave off conventional defeat. This would be accomplished by extra conventional forces. New analyses suggested that it would be easier than hitherto assumed because previous assessments had exaggerated the strength of the Warsaw Pact. In addition, the Soviet leader, Nikita Khrushchev, who was convinced that nuclear weapons made it unnecessary to maintain vast armies, was imposing major reductions on his generals at that time.

European governments argued in response that conventional forces simply could not provide a sufficient deterrent. Since Soviet territory would not be vulnerable in a conventional war, the Kremlin might judge that the risks of conventional war were acceptable. And even if the Warsaw Pact were defeated, central Europe would still be devastated. Therefore, all war had to be deterred, not just nuclear war.

In 1967 a compromise was found in the doctrine of "flexible response." Under this compromise, the Europeans recognized the U.S. requirement for an extended conventional stage, so that the first shots across the Iron Curtain would not lead automatically to nuclear holocaust, and the United States accepted the need for a clear link between a land war in Europe and its own strategic nuclear arsenal.

Limited nuclear war.   Flexible response did not prescribe a particular course of action; rather, it retained for NATO the possibility that it would be the first to use nuclear weapons and suggested that this initially would involve short-range, tactical weapons.

When tactical nuclear weapons such as the Honest John rocket were introduced into the NATO inventory during the 1950s, the U.S. Army had supposed that these could be considered quite separately from intercontinental strategic missiles. If anything, tactical nuclear weapons were closer to conventional weapons and were to be integrated with general-purpose forces. A number of strategic thinkers in the United States, including Henry Kissinger and Robert Osgood, hoped that, if the West could reinforce its military strength in this way, it would be possible to take on communists in limited nuclear wars without resort to incredible threats of massive retaliation.

However, once the widespread use of battlefield nuclear weapons by NATO was simulated in war games in the 1950s, it became apparent that they would result in such death and destruction that they could in no way be considered conventional. Also, as Warsaw Pact forces obtained comparable capabilities with such weapons as the SS-1 missile, any Western advantage seemed neutralized. Unless a retreating defender used nuclear weapons immediately, any later use could well be over his own territory and against a dispersed enemy. And, if tactical nuclear weapons were used to impose great costs on the enemy, there would be a risk that the conflict could soon escalate to strategic nuclear use. Limited nuclear war, therefore, appeared a contradiction in terms.

European governments were still loath to dispense with the weapons. Although they could not be considered ordinary weapons of war, their close integration with conventional forces meant that they were more likely than U.S. strategic nuclear forces to get entangled in a land war in Europe. The idea was to use the risk of escalating to total nuclear war with the United States as a powerful deterrent effect on the Soviet Union's actions in Europe. According to this strategy, deterrence did not require a certainty that nuclear weapons would be used, but only a risk. The consequences of miscalculation were so horrendous that a government would dare not gamble. However, the United States, whose own security was now being linked to peace in Europe, was still more concerned that miscalculation might nonetheless take place. | Linking U.S. to European security |

Certainly, NATO's procedures for "going nuclear" were designed to reduce the risk of unauthorized use. But this created a tension between theory, which suggested that deterrence was served by the risk that a conflict might get out of control, and practice, which exhibited a determination not to lose control. The tension was reflected in discussions over how to replace the first generation of tactical nuclear weapons as they became obsolete in the 1970s. If the next generation were made smaller and more precise, then this would imply a readiness to use them to fight a nuclear war rather than simply deter. An apparent readiness to wage nuclear war was at the heart of a controversy over the "neutron bomb" (actually a thermonuclear missile warhead or artillery shell of enhanced radiation and reduced blast), which was criticized for blurring the boundary between conventional and nuclear weapons and thereby making it much easier to go nuclear.

Even greater controversy was generated by NATO's decision in 1979 to replace the Pershing IA, a medium-range ballistic missile, with two weapons that would constitute a more powerful intermediate nuclear force (INF): the Pershing II intermediate-range ballistic missile (IRBM) and the Tomahawk cruise missile. The origins of the program to modernize the INF lay in two western European concerns over the U.S. nuclear guarantee. The first concern resulted from the tendency of the United States in the Strategic Arms Limitation Talks to concentrate on achieving symmetry between the nuclear forces of the two superpowers, while paying little attention to the superiority, within the European theatre, of the Warsaw Pact in both nuclear and conventional weapons. Particularly worrisome was the Soviet SS-20, an IRBM that was first tested in 1974 and deployed in 1977. Although the SS-20 did not signal any shift in Soviet policy (U.S. military bases in Europe and the British, French, and Chinese nuclear forces had long been targeted), it was the first new missile designed for this purpose to have appeared in some time. In 1977 Chancellor Helmut Schmidt of West Germany

argued that NATO should not tolerate Soviet superiority in such weapons. This suggested that the imbalance should be dealt with either through arms control or by an equivalent Western effort to upgrade its own INF.

The second concern placed far less stress on the SS-20 and more on the requirements, within NATO's strategy of flexible response, to be able to strike Soviet territory with systems based in western Europe in the event of full-scale war on the Continent. This requirement existed irrespective of the new Soviet missiles, and it was becoming problematic because of the age of NATO's medium bombers and the lack of any U.S. intermediate-range land-based missile in Europe. A modernized INF made more sense than systems designed for battlefield use, because they posed a direct threat to the Soviet homeland and thus challenged Soviet ideas of confining any nuclear exchanges to NATO and Warsaw Pact countries, with superpower territory accorded sanctuary status.

However, large-scale protests sprang up in Europe and North America after the decision to modernize. Voicing a concern that a new arms race was getting under way in Europe, they took on special urgency following the Soviet invasion of Afghanistan (two weeks after NATO's decision on the INF), with the decline of arms control, and with the election of Ronald Reagan, who had a hawkish reputation, to the U.S. presidency. The strength of the protests encouraged NATO to moderate its policy. The rationale for modernizing the INF was switched from the requirements of flexible response to the more politically marketable aim of matching the deployment of the SS-20, and in November 1981, at the start of negotiations on this issue, Reagan offered to eliminate NATO's INF if all SS-20s were removed. This "zero option" was rejected by Leonid Brezhnev, and, despite warnings from the Soviet Union that deployment of a modernized INF would mean the end of negotiations, the first Tomahawk and Pershing II missiles were delivered in late 1983. Yury Andropov promptly broke off the INF talks, hoping to force a breach in the unanimity of the NATO allies, but, when the expected crisis failed to arise, Konstantin Chernenko agreed to resume negotiations. Soon afterward Gorbachev was in charge, and he decided that the zero option was in the Soviet interest: eliminating the INF would remove a direct threat to Soviet territory in return for removing a larger number of Soviet missiles that could strike only the allies of the United States. In December 1987, Gorbachev and Reagan signed the INF Treaty.

The INF Treaty: withdrawing nuclear deterrence Although America's allies saw that the treaty had political benefits in improving East–West relations, some strategists worried that it sounded the death knell for nuclear deterrence. One response by NATO was to see whether it would be possible to build up other nuclear systems by way of compensation, but the difficulty here was that the improved political climate undermined public support for such moves. In West Germany the question of modernizing the short-range Lance missile was coloured by the direct and almost unique threat this weapon posed to German territory. There had always been the strongest official support for the traditional concept of nuclear deterrence in that country, but, with the political climate improving, West German politicians such as Chancellor Helmut Kohl came to argue that yet another nuclear modernization program would send the wrong signals to the East. They were also unhappy at the apparent readiness of the United States and Britain to retain Germany as a battlefield for short-range nuclear exchanges while securing the removal of intermediate- and long-range systems that threatened their own territories. The Soviet Union possessed large numbers of short-range missiles and had been modernizing them for a decade with such systems as the SS-21, but Gorbachev indicated a readiness to negotiate their complete elimination. British prime minister Margaret Thatcher and U.S. president George Bush insisted that this would be imprudent, and, following their lead, NATO agreed in 1989 to postpone modernizing the Lance in the hope that negotiations on conventional force reductions would reach a satisfactory conclusion and thus reduce the importance of nuclear weapons as a means of compensating for the Warsaw Pact's conventional superiority.

The Bush administration was more orthodox on nuclear matters than its predecessor, but Reagan's interest in a nuclear-free world—highlighted by SDI, the Reykjavík summit, and the INF Treaty—had already encouraged discussion among some Europeans of the possibility of a European defense community that would be less dependent upon the United States. In practice this would require the substitution of a French and British strategic nuclear guarantee for an American. Britain had always, officially at least, committed its strategic nuclear forces (which since the late 1960s had been SLBMs) to NATO. Britain's rationale for maintaining a national nuclear force involved a combination of the political influence that could be brought to bear on its allies, especially the United States, and a claim to be contributing to the overall deterrent posture. France, by contrast, had always had a much more nationalistic rationale, but after the 1970s, following the introduction of the Pluton short-range missile, which could only land on German territory, it was obliged to consider the role that its *force de frappe* might have in the defense of its allies. In any event, neither Britain nor France was eager to take over from the United States the broader deterrent role; nor were those who had previously sheltered under the U.S. umbrella interested in a European alternative.

Conventional strategy. The main consequence of the developing uncertainties surrounding nuclear deterrence was an increased interest in conventional strategy. For the first two decades of the nuclear age, there had been little interest in this area; given the conviction that any war between the great powers would soon go nuclear, there seemed to be little point in preparing for nonnuclear engagements.

Meanwhile, France and Britain fought a number of colonial wars, with France's struggles in Indochina and Algeria particularly protracted and bitter. During the 1960s the United States became steadily involved in Vietnam, in which a weak pro-Western government in the South faced an insurgency backed by a communist government in the North. After 1965 there was a substantial commitment of all elements of U.S. military power, excluding nuclear weapons but including a bombing campaign against the North.

Partly as a result of these conflicts, interest began to revive in the likely character of a conventional war involving the major powers. In the West this was also a result of the adoption of flexible response, which demanded greater attention to conventional warfare. In the East as well, to some extent because of the shift in NATO doctrine, conventional warfare grew in importance. There was some irony in this. Flexible response reflected NATO's concern over Soviet conventional superiority, yet, under Khrushchev, Soviet forces had been cut back dramatically on the assumption that any future war would go nuclear from the start. After Khrushchev was ousted in 1964, the Soviet Union began a major buildup of conventional forces, and in 1967 military exercises were held that indicated the expectation of a substantial conventional stage at the start of a future war. Besides the need to remain strong in relation to NATO, by the early 1970s the Soviet buildup reflected concern over a possible threat from China, which had become extremely hostile and was rapidly improving relations with the West. Again, there was irony in this development. China and the Soviet Union had finally split in 1963 over Khrushchev's readiness to deal with the West, over his unwillingness to back the Chinese nuclear program, and also over a long-standing border dispute between the two countries. Later, the years of the Cultural Revolution (1966–76) convinced Brezhnev that the Chinese were dangerous and unstable; clashes on the border in 1969 led to hints from Moscow that it might take action against China's fledgling nuclear capability.

In the late 1970s this Warsaw Pact buildup, coupled with Soviet-supported operations in such Third World countries as Vietnam, Angola, and Ethiopia, stimulated NATO to improve its capacity to resist an offensive and mobilize quickly. This was based on the fear that, without sufficient warning to get mobilization under way, the strength of Soviet frontline and follow-on forces could overwhelm

Renewal of conventional strategy

NATO's thin peacetime lines of defense. Growing doubts over the credibility and durability of nuclear deterrence also increased the importance of improving conventional forces.

Even with increased allocations to defense, NATO governments remained pessimistic about their ability to match Warsaw Pact forces. Although the total military power of NATO was much greater, geography favoured the Warsaw Pact, since reserves from the East could reach the front much more quickly than reserves from the United States, which would have to make a hazardous journey across the Atlantic Ocean. Against this pessimism it was noted that greater numbers were normally assumed to be required by the attacker (a ratio of three to one was often cited, although the critical factor was not the overall ratio but the strength of the offense at the point of attack). Technological advances were said further to favour the defense, in that extremely precise and comparatively simple guided weapons could be used to take on tanks and high-performance aircraft, the central actors in any offensive.

This optimism was questioned by other strategic analysts. They noted that the natural advantage accruing to the defense would do so only if the attacker had to force a way through well-prepared defensive positions, rather than simply outflanking them. The ability to impose attrition on the enemy would be reduced if the enemy was able to fight a war of maneuver, in which an immobile defense might find itself caught off balance. Moreover, in a war of maneuver, the potential benefits of simple air-defense and antitank systems would soon be qualified by the need to make them mobile, which would put them in need of protection as well.

The proponents of maneuver warfare warned that this was the type favoured by the Warsaw Pact. The Soviet Union preferred the offensive because it would make it possible to defeat the enemy quickly, before the full weight of its power could be brought to bear. Soviet doctrine during the 1970s suggested that a key aspect of this offensive would be the neutralization of NATO's nuclear assets by overrunning key installations, with a possible shift to a regional nuclear offensive when the right moment arrived. By the early 1980s doubts over whether a war would last long enough for the right moment ever to arrive, and whether nuclear exchanges could be limited geographically, encouraged a greater stress by the Soviet military on obtaining a victory in the conventional stage.

The maneuver school eventually encouraged a shift in NATO thinking toward more mobile operations, as well as a greater willingness to contemplate attacks into Warsaw Pact territory in an effort to reduce the momentum of a Pact offensive. The strategy of follow-on forces attack (FOFA), for example, envisaged the holding of a Pact offensive on the ground while attacking the Pact's follow-on forces in the rear with air strikes. Such aggressive defense was criticized by peace movements as being too provocative. Instead, they proposed non-provocative strategies based on "defensive defense," which would lack any capability to go on the offensive. These ideas proved difficult to turn into practice, as any sort of mobile force could move forward, and few armies would tolerate being deprived of their capacity to counterattack.

Meanwhile, in the Soviet Union concern over the burden of high defense expenditures, combined with an awareness that the arms buildup of the 1970s had triggered a counterresponse from NATO, encouraged "new thinking" that actually picked up on the ideas of defensive defense. These ideas were received by Soviet military commanders with as little enthusiasm as they were received in the West. Nevertheless, they influenced cuts in Soviet forces, announced by Gorbachev in December 1988, that eliminated some military units of a clearly offensive nature without depriving the Warsaw Pact of its offensive options. However modest in themselves, the cuts raised the prospect of an end to the role of these forces in sustaining the Soviet Union's dominance over eastern Europe. When coupled with domestic political reforms in the Soviet Union, Poland, and Hungary, they also signaled the eventual demise of the postwar alliance system. The prospect of a declining Soviet hegemony, however, was clouded by

growing disorder within eastern Europe (and even in the Soviet Union itself) and also by the considerable strength that Soviet military forces would retain in spite of the planned cuts. Moreover, there was no reason to presume that a security system in which the two superpowers played a less overbearing role would be free of conflict. This provided an argument for a continuing role for nuclear deterrence: to warn against the dangers of allowing any conflict to get out of hand, if not to deal with a specific military threat. Nevertheless, political changes within the Soviet bloc presented a historic opportunity to heal East–West divisions and, with that, to reduce the need for substantial armed forces of any kind.   (L.D.Fr.)

Tactics of land warfare

FUNDAMENTALS

Evolution of the term. The word *tactics* originates in the Greek *taxis,* meaning order, arrangement, or disposition—including the kind of disposition in which armed formations used to enter and fight battles. From this, the Greek historian Xenophon derived the term *tactica,* the art of drawing up soldiers in array. Likewise, the *Tactica,* an early 10th-century handbook said to have been written under the supervision of the Byzantine emperor Leo VI the Wise, dealt with formations as well as weapons and the ways of fighting with them.

The term tactics fell into disuse during the European Middle Ages. It reappeared only toward the end of the 17th century, when "Tacticks" was used by the English encyclopaedist John Harris to mean "the Art of Disposing any Number of Men into a proposed form of Battle." Further development took place toward the end of the 18th century. Until then, authors had considered fighting to be almost the sum total of war; now, however, it began to be regarded as merely one part of war. The art of fighting itself continued to carry the name tactics, whereas that of making the fight take place under the most favourable circumstances, as well as utilizing it after it had taken place, was given a new name: strategy.

Since then, the terms tactics and strategy have usually marched together, but over time each has acquired both a prescriptive and a descriptive meaning. There have also been attempts to distinguish between minor tactics, the art of fighting individuals or small units, and grand tactics, a term coined about 1780 by the French military author Jacques-Antoine-Hippolyte de Guibert to describe the conduct of major battles. However, this distinction seems to have been lost recently, and the concept of grand tactics has been replaced by the concept of the so-called operational level of war. This may be because, as will be discussed below, battle in the classical sense—that is, of a pitched encounter between the belligerents' main forces—no longer exists.

Victory through force and guile. The tactics adopted by each separate army on each separate occasion depend on such circumstances as terrain, weather, organization, weaponry, and the enemy in addition to the purpose at hand. Nevertheless, while circumstances and purposes vary, the fundamental principles of tactics, like those of strategy, are eternal. At bottom they derive from the fact that, in war, two forces, each of which is free to exercise its independent will, meet in an attempt to destroy each other while at the same time attempting to avoid being destroyed. To achieve this double aim, they can rely on either force or guile. Assuming the two sides to be approximately equal—in other words, that neither is so strong as to be able to ride roughshod over the other (in which case tactics are hardly required)—a combination of both force and guile is necessary.

To employ force, it is necessary to concentrate in time and place. To employ guile, it is necessary to disperse, hide, and feint. Force is best generated by taking the shortest route toward the objective and focusing all available resources on one and the same action, whereas guile implies dispersion, the use of circuitous paths, and never doing the same thing twice. These two factors, most conducive to victory in battle, are not complementary; on the contrary, they can normally be employed only at each

other's expense. In this way tactics (as well as strategy) are subject to a peculiar logic—one similar to that of competitive games such as football or chess but radically different from that governing technological activities such as construction or engineering, where there is no living, thinking opponent capable of reacting to one's moves. To describe this kind of logic, the American military writer Edward Luttwak has used the term paradoxical. The title is apt, but the idea is as old as warfare itself.

Putting the enemy on the horns of a dilemma

The single most effective means available to the tactician consists of putting his enemy on the horns of a dilemma—deliberately creating a situation in which he is "damned if he does and damned if he does not." For example, commanders have always attempted to outflank or encircle the enemy, thus dividing his forces and compelling him to face in two directions at once. Another example, well known to the early modern age, consisted of confronting the enemy with coordinated attacks by cavalry and cannon—the former to force him to close ranks, the latter to compel him to open them. A good 20th-century example was the World War I practice—revived by the Iraqis in their war against Iran in the 1980s—of shelling the enemy's front with a combination of high explosive and gas. The former was designed to compel him to seek cover, the latter, being heavier than air, to abandon it on pain of suffocation.

The need for flexibility.   Thus considered, the principles of tactics look simple enough. However, it is one thing to analyze tactics in the abstract but entirely another thing to put theory into practice under different circumstances, on different kinds of terrain, against different kinds of enemy, with the aid of troops who may be tired or confused or recalcitrant, and amid every kind of mortal danger. As the great Prussian general Carl von Clausewitz said, "In war everything is simple, but even the simplest thing is difficult." Sophisticated tactics require well-trained, articulated forces consisting of different units that are armed with different weapons and possess different capabilities. Next, these units must be subordinated to a single directing brain and must be employed in a coordinated manner following a single, well-considered plan: hence the principle of unity of command.

Even then, tactics are not just a question of executing a plan, however clever and well conceived. In tactics, even more than elsewhere, a commander who can only make a plan and carry it out avails nothing; inasmuch as he is confronting a living enemy, what matters is his ability to adapt the plan to that enemy's reactions rapidly, smoothly, and without losing his grip. Flexibility is thus a cardinal

Combining flexibility and discipline

principle of tactics. But flexibility will prevail only if it can be bound by a firm disciplinary framework. Moreover, flexibility and discipline are not easy to combine and can often be achieved only at each other's expense. Other things being equal, the larger and more powerful a given force, the less flexible it will be.

As an armed force exchanges blows with an enemy, adapting to his moves and forcing him to adapt in return, opportunities to take him by surprise should present themselves. Surprise presupposes secrecy, but secrecy may be hard to combine with the rapid action that is often necessary for implementing surprise. Like everything else in tactics, overcoming this paradox is a matter of striking a balance, first in general and then against a specific enemy, under specific circumstances and with a specific objective in mind.

The importance of terrain.   Finally, in tactics (as in strategy) there is the topographical element to consider. Land warfare is fought neither in a vacuum nor on a uniformly checkered board. Instead, it unfolds over concrete terrain, including roads, passages, elevated ground, cover, and obstacles of every kind. Victory goes to him who best understands and utilizes the terrain; this may be done by, for example, occupying dominant ground, utilizing cover, compelling the enemy to fight on terrain for which his forces are not suitable, cornering him, outflanking him, or surrounding him. All these methods are as old as warfare, yet at the same time they remain relevant to the present age. On their correct application the outcome of battle depends.

Tribal and ancient tactics.   *The ambush and the trial of strength.* The oldest, most primitive field tactics are those that rely on concealment and surprise—*i.e.,* the ambush and the raid. Such tactics, which are closely connected to those used in hunting and may indeed have originated in the latter, are well known to tribal societies all over the world. Typically the operation gets under way when warriors, having reconnoitred the terrain and stalked their enemy, take up concealed positions and wait for the signal. The engagement opens by means of such long-range missile weapons as the javelin, the bow, the sling, and the tomahawk. Once the enemy has been thrown into disorder and some of his personnel killed or wounded, cover is discarded, and short-range weapons such as club, spear, and dagger are employed for delivering the coup de grace. Since concealment is vital and there is no sophisticated logistic apparatus, the number of combatants is usually no more than a few dozen or, at the very most, a few hundred. Tactical units are unknown and command arrangements, to the extent that they exist at all, elementary. None of this, however, is to say that such tactics are simpleminded. On the contrary, making the best use of difficult terrain such as mountains, forests, or swamps usually requires much skill and presupposes an intimate familiarity with the surroundings.

Tactical demands of the ambush

Apart from ambush and raid, which depend on making the best possible use of terrain, many primitive tribes also engage in formal, one-to-one frontal encounters that are part battle, part sport. The weapons employed on such occasions usually consist of the club (or its more advanced form, the mace), spear, and javelin, sometimes joined by the bow and special blunted arrows. Defensive armour consists of nonmetallic body cover of wood, leather, or wickerwork, often made in fantastic forms and painted extravagant colours in order to enlist the aid of spirits and terrify the opponent. Such fights differ from those described above in that the warriors stand in full view of each other across specially selected level terrain, the objective being to please the spectators and gather glory for themselves. However, here too there can be no question either of formations or of a command system. Rather, each man picks his opponent and fights separately. Hence, it is impossible to speak of tactics, except in the limited sense of the skill displayed by individual warriors in handling their weapons.

The phalanx.   To judge from numerous descriptions in Homer, archaic Greek warriors still acted in this way. The heroes on each side knew each other they by reputation and sought each other out, forming pairs and fighting hand-to-hand without any regard for either collective action or the discipline and organization that were needed for it. However, the *Iliad* also contains passages that may indicate a more advanced form of tactics—namely, the phalanx. Phalanx tactics are known from ancient Sumer and Egypt as well as from Greece. Their essence consisted of packing troops together in dense, massive blocks, to some extent sacrificing flexibility, mobility, and the possibility of concealment in order to achieve mutual protection and maximize striking power. In Greek armies the usual number of ranks was 8, but formations 16 and even 50 deep are recorded. Insofar as they relied on brute force, such tactics were often considered primitive even in their own day—for example, by the Persian commander Mardonius in describing them to his master, Xerxes I. For a phalanx to execute even a simple lateral evasive move, the troops had to be "professors of war"; such was the Roman historian Plutarch's expression in describing the disaster suffered by Sparta at the Battle of Leuctra in 371 BC. As Sumerian reliefs, Egyptian wooden models, and Greek narratives show, the typical weapons employed by the phalanx were consistently short-range, hand-held instruments such as sword, spear, and pike, used in accordance to whether individual duels or mass action was considered more important. These weapons were invariably combined with defensive gear such as helmets, corselets, shields, and greaves, although here too the amount of protection varied from one case to the next.

The chariot.   Invented in the 3rd millennium BC, the

first chariots seem to have been too slow and cumbersome to serve in combat, but about 2000 BC the light, horse-drawn, two-wheeled vehicles destined to revolutionize tactics appeared in the Western Steppe and Mesopotamia, Syria, and Turkey, from which they spread in all directions. In combination with the bow, the chariot represented a very effective system, so much so that in biblical times it became almost synonymous with military power. The

Running circles around the phalanx

great advantage of the chariot was its speed, which permitted it to drive circles around the phalanx, staying out of range while raining arrows on the foot soldiers. Once the latter had been thrown into disorder, it might be possible to put the chariots into formation, charge, and ride the enemy down. Relying on such tactics, the chariot-riding Aryan peoples were able to undertake some of the most extensive conquests in history, spreading over the Eurasian landmass and inflicting crushing defeats on the materially much more advanced Egyptian and Indian civilizations. The chariot's principal drawbacks were its expense and unsuitability for difficult terrain. Also, it made inefficient use of manpower, since each vehicle required a crew of two and sometimes three men—only one of whom actually handled offensive weapons and struck at the enemy.

Light and heavy cavalry. The next development following chariots was cavalry, which took two forms. From Mongolia to Persia and Anatolia—and, later, on the North American plains as well—nomadic peoples fought principally with missile weapons, especially the bow in its short, composite variety. Equipped with only light armour, these horsemen were unable to hold terrain or to stand on the defensive. Hence, they were forced to employ their characteristic highly mobile "swarming" tactics, riding circles around the enemy, keeping their distance from him, showering him with arrows, engaging in feigned retreats, luring him into traps and ambushes, and forming into a solid mass only at the end of the battle with the aim of delivering the coup de grace. Being obliged to keep their possessions few and light, nomads typically were unable to compete with sedentary civilizations in general material development, including not least metallurgy. Nevertheless, as the Mongols' campaigns were to show, their war-making methods, natural hardihood, and excellent horsemanship made them the equal of anyone in either Asia or Europe until at least the end of the 13th century AD.

Among the technically more advanced sedentary civilizations on both edges of the Eurasian landmass, a different kind of cavalry seems to have emerged shortly after 1000 BC. Reliefs from great Assyrian palaces show horsemen, clad in armour and armed with spear or lance, who were used in combination with other troops such as light and

The cataphract

heavy infantry. The function of these cataphracts (from the Greek word for "armour") was not to engage in long-distance combat but to launch massed shock action, first against the enemy cataphracts and then, having gained the field, against the enemy foot. The fact that ancient cavalry apparently did not possess the stirrup has often led modern historians to question the mounted soldier's effectiveness. They argue that, since riders held on only by pressure of their knees, their ability to deliver shock was limited by the fear of falling off their mounts. This argument fails to note that, particularly in Hellenistic times and again in late Roman ones, cavalry forces did indeed play an important, often decisive, part in countless battles. Still, it is true that never during classical antiquity did cavalry succeed in replacing the formations of heavy infantry that remained the backbone of every army.

Combined infantry and cavalry. Classical Greek warfare, as mentioned above, consisted almost exclusively of frontal encounters between massive phalanxes on both sides. However, about the time of the Peloponnesian War (431–404 BC), the phalanx became somewhat more articulated. This permitted the introduction of elementary tactical maneuvers such as massing one's forces at a selected point, outflanking the enemy, and the oblique approach (in which one wing stormed the enemy while the other was held back). In addition, the phalanx began to be combined with other kinds of troops, such as light infantry (javelin men and slingers) and cavalry. Indeed, the history of Greek warfare can be understood as a pro-

cess by which various previously existing types of troops came to be combined, integrated, and made to support one another. This development gained momentum in 4th-century battles, such as the one fought by Thebes against the Thessalians at Cynoscephalae in 364 BC, and it culminated in the hands of Alexander III the Great, whose army saw most of these different troops fighting side by side. The major exception was horse archers, which were incompatible with a settled way of life and which never caught on in the West. Another was the chariot, which was already obsolescent and, except in backward Britain, disappeared almost completely after its defeat at the Battle of Gaugamela in 331 BC.

Commanding standing armies consisting of professionals, Alexander and his successors (*diodochoi*) operated on a much greater scale than did most of their predecessors. The most important *diodochoi* were quite capable of concentrating 80,000 to 100,000 men at a single spot, as did both Ptolemy IV and his Seleucid opponent Antiochus III at Raphia in 217 BC. These armies typically went into battle with a force of light infantrymen in front (elephants were sometimes used, but on the whole they proved as dangerous to their own side as to the enemy). Behind the

The flanking maneuver

light troops came the heavy phalanx, flanked by cavalry on both sides. The action would start with each side's light troops trying to drive the opponents back upon their phalanx, thus throwing it into disorder. Meanwhile, the cavalry stood on both sides. Usually one wing, commanded either by the king in person or by one of his closest subordinates, would storm forward. If it succeeded in driving away the opposing cavalry—and provided it remained under control—it could then swing inward and act as the hammer to the phalanx's anvil. Such were the methods by which the great Hellenistic battles such as Gabiene (317 BC) and Ipsus (301 BC) were won. The same applied to the one fought by Hannibal at Cannae in 216 BC; this owed its exceptionally decisive character to the envelopment of the Roman infantry by two cavalry arms instead of one.

The legion. Though its exact origins are unknown, the Roman legion seems to have developed from the phalanx. In fact, it was a collection of small, well-integrated, well-coordinated phalanxes arrayed in checkerboard formation and operating as a team. Hellenistic heavy infantry relied on the pike almost exclusively; the legion, by contrast, possessed both shock and firepower—the former in the form of the short sword, or *gladius,* the latter delivered by the javelin, or *pilum,* of which two (after 100 BC, all) legionnaires carried two. Screening was provided by light troops moving in front, cohesion by pikemen in the third and rearmost rank. Short arms made it easier for individual soldiers or subunits to turn and change direction. Too,

careful articulation, a well-rehearsed command system, and the use of standards—which do not seem to have been carried by Hellenistic armies—made the legion a much more flexible organization than the phalanx. No Greek army could have imitated the movement carried out by Caesar's troops at Ruspinum in Africa in 47 BC, when part of a legion was made to turn around and face an enemy cavalry force coming from the rear. As numerous battles showed, where the terrain was uneven and the chain of command broke down, the legion's advantage was even more pronounced. A phalanx whose ranks were thrown into disorder and penetrated by the enemy's infantrymen was usually lost; a legionary commander could rely on his soldiers' swords to deal with intruders, meanwhile bringing up additional units from both flanks.

As a formation whose main power consisted of its heavy infantry, the legion remained unmatched until the introduction of firearms and beyond. Attempts to imitate its armament and methods were made right down to the 16th century, and even today some countries still call their forces legions in commemoration of its prowess. During the 1st century BC, legionary organization underwent some changes at the hands of Gaius Marius and Lucius Cornelius Sulla until it reached the zenith of its development about the time of Caesar. Subunits became larger, and the legion incorporated a detachment of heavy cavalry as well as field artillery in the form of catapults—thus turning into a combined-arms unit and becoming a true forerunner of the modern division. Yet the legion, too, *Limitations* had its limitations when it came to fighting in the dense *of the* forests of Germany or, even more so, the open deserts of *legion* the Middle East. As Marcus Licinius Crassus' disastrous defeat at Carrhae in 53 BC demonstrated, it met its match in the eastern light cavalry, with which it could never really come to grips, so that, even after repeated attempts, the Romans failed to subdue Parthia as they had so many other countries. The lesson was not lost. From the time of Belisarius in the 6th century AD, the Byzantine army always supplemented its infantry and heavy cavalry with units of horse archers, usually consisting of mercenaries recruited from various barbarian tribes. In this way, they were able to counter the Arabs and, later, the Seljuqs.

Medieval tactics in the West. *The barbarians.* Whatever their differences, Byzantine armies were the direct heirs of the Roman legions in that they consisted of various kinds of troops in well-organized, centrally commanded units. Meanwhile, developments in the Latin West followed a different course. From the 1st-century historiography of Tacitus through the above-mentioned *Tactica* down to the Old English epic *Beowulf,* such scarce sources as survive describe the Germans who brought down the Western Roman Empire as seminomadic tribes rather than settled,

urban societies. Commanded not by officers but by chieftains, they were formidable foot soldiers more notable for physical prowess and courage than for tactical organization. Weapons were mostly hand-held and included the sword, spear, and javelin. To these the Franks added the heavy battle-axe, or *francisca,* useful for both hacking and throwing. Defensive arms consisted of the usual helmets, corselets, greaves, and shields—although, since metal was expensive, most warriors seem to have worn only light armour. Sources mention the names of some tactical formations such as the hogshead, which apparently consisted of phalanxlike heavy blocks, but movement may have been carried out in smaller units, or *Rotte.* Germanic formations and tactics must have been effective, for in the end they overcame—or rather superseded—the Roman legions; how it was done, though, simply is not known.

The mounted knight. If sources can be trusted, the Franks still fought mainly on foot when they defeated the Moors at Poitiers in 732 AD. About the time of Charlemagne, later in the 8th century—and possibly aided by the stirrup, which was introduced to Europe from the East—they took to horse and became knights. Typically, knights carried elongated, kite-shaped shields and wore a complete suit of metal armour (sometimes the horse too was armoured). Their principal offensive weapon was the *Use of the* lance. Originally, this was comparatively light and short, *lance* and it could either be held overhead (or even thrown, as shown in the Bayeux Tapestry) or else gripped underhand parallel to the horse's body. However, about the year 1100 the technique of couching the lance under the arm was introduced. This permitted it to grow much longer and heavier and also meant that knights were becoming more specialized for fighting other knights. The secondary weapon was the sword, which, like the lance, tended to grow longer and heavier with time. Knights would open combat with the lance and continue it with the sword, fighting either on horseback or, if forced to dismount, on foot. In time, chain-mail armour tended to be replaced by stronger, but less flexible, plate. The new suits, which steadily grew heavier, rendered their wearers less capable of dismounted action and, as legend has it, allowed them to get on horseback only with the aid of a crane.

By virtue of their mobility, height above the ground, and sheer weight, knights possessed a tremendous advantage over foot soldiers, especially those caught on open terrain and not operating in organized formations. Though social differences among knights were very great, in principle each regarded himself as militarily the equal of every other. In addition, since feudal armies were made up entirely of officers, as it were, they tended to be ill-organized, ill-disciplined, and prone to sedition. Only on occasion were there attempts at tactical organization and a regular chain

Figure 2: *Medieval armoured cavalry at the Battle of Hastings (1066).*

of command. If modern reconstructions can be trusted, armies might enter battle in an orderly manner, usually operating in three divisions with the commander in chief in charge of the rearmost one. However, medieval princes such as Harold II of England, William I the Conqueror, and Richard I the Lion-Heart were expected to engage in hand-to-hand combat or else, by showing cowardice, lose standing in the eyes of their subordinates. Therefore, it was seldom long before engagements ran out of control and degenerated into cavalry melees. Fighting as individuals or in small groups, knights clumped together and hacked away indiscriminately at each other. Since armour was heavy and quarter usually given (to be followed by the payment of ransom), casualties among the chivalry were often light. One side having succeeded in killing, capturing, or driving off the other's horsemen, the foot soldiers present would be slaughtered like cattle.

Knights against horse archers

The European system centring on armoured shock cavalry was only moderately effective when faced with the swarming horse archers of the East. Against the Saracens during the Crusades, for example, it was capable of holding its own—provided the knights were kept on a tight rein and did not allow themselves to lose cohesion, become separated from the foot soldiers, or fall into an ambush. Such methods gave good results when employed by Richard the Lion-Heart in the Battle of Arsūf in 1191; however, when necessary precautions were not taken and inter-arm cooperation broke down, the outcome could well be disastrous defeat, as at Ḥaṭṭin four years earlier. Employed against the Mongol invaders of Europe, knightly warfare failed even more disastrously for the Poles at Legnica and the Hungarians at Mohi in 1241. Feudal Europe was saved from sharing the fate of China and Muscovy not by its tactical prowess but by the unexpected death of the Mongols' supreme ruler, Ögödei, and the subsequent eastward retreat of his armies. Nevertheless, within Europe itself for a period of perhaps three centuries, the best and indeed almost the sole means of stopping one troop of armoured cavalry was another troop of armoured cavalry.

Bowmen and pikemen. The first field tactics that proved capable of countering the knight were built around the bow and the crossbow. Both might be used either in difficult terrain or from behind some artificial obstacle such as pits (as at Bannockburn in 1314), stakes (as at Crécy in 1346, Poitiers in 1356, and Agincourt in 1415), or a trench dug in the earth. The bow in its most powerful form, the longbow, was a cheap, low-class weapon originally associated with primitive social organizations such as the Welsh tribes. The crossbow, a much more expensive and sophisticated weapon, was typically employed by urban militias and mercenaries. The two weapons' technical characteristics were somewhat different, especially as regards the crossbow's shorter range, lower rate of fire, and greater penetrating power; as a result, they were seldom seen side by side in the same battle. However, both were capable of defeating armour, even the heavy plate worn toward the close of the Middle Ages, and were therefore useful against knights when properly employed. Proper employment meant selecting suitable positions and forming long, thin formations, sometimes in the form of a shallow W in order to trap attackers and enfilade them. Because formations such as these were difficult to move from place to place, they and the weapons on which they were based were better suited for the defense than for the offense.

This particular disadvantage was not shared by two other nonchivalrous weapons, the halberd and pike. Pikes were used by the Scots against Edward I at Falkirk in 1298 and by the Flemish against French chivalry at Courtrai in 1302. Subsequently they became the specialty of the Swiss, who, for topographical and economic reasons, never had much use for horses and knightly trappings. A *Haufe* (German: "heap") of Swiss infantry had much in common with a Macedonian phalanx, except that it was smaller and more maneuverable. Most of the troops seem to have been lightly armoured, wearing helmet and corselet but not being burdened by either greaves or shield. Hence, they possessed good mobility and formidable striking power. The first shock would be delivered by the pikes sticking out in front, after which the halberdiers would leave for-

The Swiss phalanx

mation to do their deadly work. The Swiss differed from the Macedonians in that they did not combine the phalanx with cavalry but relied on infantry for both fixing the enemy and striking him. Usually they entered battle in three columns moving independently, thus permitting a variety of maneuvers as well as mutual support. An enemy could be engaged from the front, then hit in the flank by a second *Haufe* following the first in echelon formation.

Though it is hard to be certain, apparently the hard-marching Swiss possessed sufficient operational mobility to keep up with cavalry, at any rate in confined terrain such as Alpine valleys. If the worst occurred and an isolated column was caught in the open, the troops could always form a square or hedgehog, facing outward in all directions while keeping up a steady fire from their crossbows and relying on their pikes to keep the opposing horse at a respectful distance until help arrived. Whereas the Scots inhabited a northern wilderness, the Swiss were located in the centre of Europe, and, whereas the Flemish went down in front of French chivalry at Roosebeke in 1382, the Swiss won a series of spectacular victories at Morgarten (1315), Laupen (1339), Sempach (1386), and Granson (1476). These two factors combined to give Swiss tactics a reputation in Europe. From about 1450 to 1550, every leading prince either hired Swiss troops or set up units, such as the German *Landsknechte,* that imitated their weapons and methods—helping to bring down the entire feudal order.

Inferiority of medieval tactics. Compared to the most powerful ancient armies, however, even late medieval ones were impermanent and weak. Numbers never approached those fielded during Hellenistic and Roman times: it was a mighty medieval prince who could assemble 20,000 men (of whom perhaps 5,000 would be knights), and most forces were much smaller. Apart from the stirrup, an invention whose importance may have been exaggerated by modern historians, no important advances took place in military technology. Consequently, tactics tended to repeat themselves in cycles rather than undergo sustained, secular development—as was to become the case after 1500 and, above all, after 1830. If only because medieval discipline was often lax and organization usually elementary, sophisticated tactical maneuvers such as those which characterized the armies of Alexander, his Hellenistic successors, and the Romans at their best were few and far between. Otherwise put, the knightly system of making war was much more individualistic than its classical predecessors; had the two been pitted against each other, the earlier forms would likely have overcome the later.

The **advent of firearms.** *Adaptation of pike and cavalry tactics.* Gunpowder apparently reached Europe from the East shortly before 1300, and firearms appeared during the 14th century. Throughout the 15th century firearms and crossbows continued to be used side by side. The first battles actually to be decided by firearms were fought between French and Spanish troops on Italian soil early in the 16th century; these included Marignano (1515), Bicocca (1522), and, above all, Pavia (1525).

The first firearms were primitive devices lacking both buttstock and trigger; hence, they had to be held under the arm and could scarcely be aimed. It was only during the second half of the 15th century that the harquebus, which incorporated both of these features, made its appearance. This was a great improvement, but the harquebus still suffered from a low rate of fire as well as inaccuracy and unreliability. In order to compensate for these disadvantages and build staying power, 16th-century units such as the famous Spanish tercio were made up of pikemen surrounded by "sleeves" of harquebusiers on each corner. Much like the light armed troops of antiquity and the crossbowmen who accompanied the Swiss *Haufen,* harquebusiers would open the action and then retreat behind the pikemen as the latter came to close quarters with the enemy. Hence, 16th- and early 17th-century battles still tended to be decided by "push of pike," as the saying went.

In the face of such formations, lance-carrying cavalry operating on its own was almost helpless. During the 16th century, an attempt was made to adapt cavalry to the new circumstances by arming it with short firearms

The harquebus

such as pistols and carbines. These were difficult to load on horseback and had neither the range nor the accuracy to permit Mongol-style swarming tactics. Instead, the cavalrymen carrying them were trained to attack infantry formations by approaching them in serried ranks, firing at point-blank range, and withdrawing in turn—a maneuver resembling the orderly moves of a ballroom dance and known as the caracole. Insofar as they sacrificed the cavalry's greatest advantages—namely, its mobility and sheer mass—such methods were never very effective. A much better system was to rely on combined arms, bombarding infantry formations with artillery (another 14th-century invention that began to make its impact felt on the battlefield from about 1500) and then, once the infantry had been shattered, sending in the heavy cavalry to complete the job with cold steel. Such methods were typical of Gustav II Adolf and Oliver Cromwell about the middle of the 17th century.

The state-owned army. As European firearms improved, the old situation in which each people possessed its own weapons and, therefore, its own system of organization and tactics disappeared. From about 1600, so great was the superiority of European arms and military methods that non-European societies could survive, if at all, only by excluding or imitating them. Inside Europe, too, armies and tactics became increasingly alike. Gone were the days when one nation specialized in heavy cavalry, another in light cavalry, still another in pikemen, archers, or crossbowmen. Everywhere armed forces were becoming divorced from society at large and growing into regular, state-owned organizations that tended to resemble one another. These similarities were reinforced by the international character of warfare, which for centuries on end permitted individuals and even entire units to move from one service to another.

Three branches of the army   During the second half of the 16th century, every army came to consist of three arms: infantry, cavalry, and artillery. The trend was to add more and more of the first and third arms, while the second, though retaining its high social prestige, underwent a relative decline in numbers and importance. By the early 18th century a fourth arm, engineering, had differentiated itself from artillery, an arrangement that became standard in all armies after the Seven Years' War (1756–63). Particularly after 1683, the year in which the Turks mounted their last major challenge and were repulsed at the gates of Vienna, European armies grew accustomed to seeing one another as their strongest opponents. Since they organized, trained, and equipped themselves to fight one another, there was a tendency to distinguish *les grandes opérations de guerre* from *guerrilla,* or small war, which was increasingly left to so-called free corps, or irregulars. As the regulars came to rely on heavier and heavier weapons, the gap between the two kinds of warfare grew. Ultimately, this specialization was to cost armies the ability to fight opponents that did not resemble themselves, but in the 17th century that development still remained far in the future.

Linear formation. Meanwhile, the improvement of firearms caused armour to be discarded. Infantry ceased wearing it almost completely after 1660, and the armour carried by cavalrymen grew steadily shorter until all that remained were the breastplates worn by heavy cavalry—the cuirassiers—as late as the 20th century. The harquebus developed into the heavier, more powerful musket, which soon acquired the flintlock firing mechanism. This was scarcely the perfect weapon, but it could be relied on to fire two or three times per minute to an effective range of 100–150 yards without misfiring more than 20 percent of the time. There was a constant tendency to increase the number of musketeers at the expense of pikemen until, by the end of the Thirty Years' War (1618–48), their proportions had become about equal. To allow the maximum number of barrels to fire without mutual interference, tactical units grew smaller, and the number of ranks drawn up behind one another declined. From 8 to 10 at the time of Prince Maurice of Nassau early in the 17th century, it came down to 4 or 5 a century later, 3 or 4 in the armies of Frederick the Great, and 2 or 3 toward the end of the 18th century.

To maximize efficiency, drill was invented. It first made   Drill its impact felt in the Dutch army under Maurice of Nassau, a great teacher whose headquarters attracted aspiring officers from all over Europe. Standards, often modeled after Roman ones, were introduced to help units align themselves, and tactical movements were carried out to the sound of trumpets, bugles, and drums—the latter an Oriental innovation apparently brought to Europe about 1500. In this age of René Descartes, Thomas Hobbes, and Louis XIV, each of whom in his different way was determined to reduce the world to order, the military ideal was to achieve maximum reliability and efficiency by training troops to operate in a machinelike manner. This implied much tighter discipline and organization, which in turn required a shift toward the type of regular, professional forces that alone were capable of achieving them.

About 1670 the bayonet was invented, causing pikes to be discarded and homogeneous infantry to be created (though the expression "to trail a pike" lingered for another century). Apart from predicaments when it had to form squares in order to confront attacking cavalry, infantry now fought in very long, thin formations. Throughout the 18th century a lively debate was carried on concerning the best ways to employ these formations, but basically each side organized its forces in two lines separated by perhaps 300 to 400 yards and moving forward one behind the other. Though the precise arrangements varied from one army to the next, inside each line the units were organized by platoon, company, and battalion. Advancing toward each other, each side would hold its fire for as long as possible in order to close range and obtain a better aim, and then, acting upon the word of command, the opposing lines would fire salvo after salvo into each other. The final step consisted of fixing bayonets and storming the enemy—although, since one side usually broke, actual hand-to-hand fights seem to have been rare. Flank protection was provided by light cavalry such as dragoons or hussars, which were introduced in force between 1690 and 1740. Heavy cavalry would be held in reserve, ready to strike when a gap was created or a flank presented itself. During the second half of the 18th century another type of cavalry, the lancers, was added specifically to root out gunners hiding under their cannons' barrels.

The first cannon were slow-firing devices much too cum-   Field bersome to take part in tactical maneuvers, and indeed so   artillery heavy were they that until about 1500 they were not even provided with wheels. Even then, the standard method was to position the guns in the intervals between units and in front of the advancing lines. This permitted them to open the battle but subsequently forced them to fall silent as the army advanced and left the gunners behind. To solve this problem, there was a steady tendency to make artillery smaller and more mobile, from the "leather guns" fielded by Gustav Adolf in the 1630s to the horse artillery developed after 1760—by which time anything heavier than 12-pounders (that is, firing 12-pound [5.4-kilogram] balls) was no longer considered suitable for battlefield use. It then became possible to move the guns during the combat, massing them against selected sections of the enemy front as the tactical situation might require. This flexibility, however, was offset by the fact that 18th-century linear formations were almost impossible to turn around. Hence, the really artistic touch consisted of so arranging things as to fall with one's whole force upon one of the enemy's flanks; witness the great victories that Frederick the Great, employing his so-called oblique order, achieved at Rossbach and Leuthen in 1757.

The French Revolution. The tactics of the French ancien régime received their final form in the Ordinance of 1791, which reflected the ideas of Jacques de Guibert; from then until 1831, when the next regulations appeared, formally speaking there was no change. The French Revolution was followed by a short period of tactical improvisation, brought about by the inexperience of the Revolutionary troops, who, unlike their predecessors, were not long-serving regulars but conscripts. However, order was soon restored, and at Jemappes in November 1792 French troops could be observed maneuvering with the best. As the British general Archibald Percival

Napoleon
as a
tactician

Wavell observed more than a century later, Napoleon was probably a greater strategist than he was a tactician. While he continued the work begun by the Revolution, perhaps his most important tactical innovation consisted of an increased reliance on skirmishers. Previous armies had also made use of skirmishers, but these were mostly irregulars such as the Austrian Pandours or the farmers who fired the opening shots in the American Revolution. Since desertion was less of a problem in post-1793 French armies, they could afford to employ regulars in this task. Deploying without any organized formations, skirmishers were permitted to open battles by moving as they saw fit, alternately firing and taking cover. They soon formed as much as one-third of the infantry. Meanwhile, lighter, better-designed artillery (following the system designed by Jean-Baptiste Vaquette de Gribeauval in the last years of the ancien régime) played an ever-increasing role, particularly since the quality of Napoleon's infantry tended to decline after 1808. This permitted "grand batteries" to be assembled in the midst of battle and fire to be concentrated against selected spots in the enemy front until it was torn to shreds.

These changes apart, the bulk of armies, formed by infantry, continued to deploy much as they had before, and there is no evidence that French methods differed considerably from the rest. Having committed their skirmishers and cannonaded the enemy lines, commanders would form the infantry into one or more columns to launch the assault. Heavy cavalry would be held in reserve to deliver the coup de grace, and this would be followed by light cavalry, which was responsible for pursuit. Perhaps the most effective defensive tactics to counter this system were developed by the Duke of Wellington in Spain during the Peninsular War (1808–14). These consisted of drawing up the troops on the reverse side of a ridge, out of the reach of the attacker's artillery, and then allowing the enemy infantry to approach until they could be blasted at almost point-blank range.

Tactics from Waterloo to the Bulge. *The growing scale of battle.* In many ways, the Battle of Waterloo in 1815 constituted a crucial turning point in the tactics of land warfare. Until then, even though weapons and methods had varied greatly, land battles had essentially been single events, taking up a few square miles and lasting no more than a few hours or a day at most. Consisting of formal trials of strength between the main forces of both sides, often enough battles resulted from a kind of tacit mutual consent to commence hostilities. Shifting an army from deep marching columns to thinner and wider fighting formations was a lengthy process; hence, battles very often took on a quasi-ceremonial, paradelike character and were attended by much pomp and circumstance. The short range of weapons—never more than a few hundred yards, usually much less—dictated lateral deployment in order to bring every available man (apart from tactical reserves) into action. Moreover, the means of communication, which had scarcely undergone any change since the dawn of history, imposed definite limits on the length of the fronts that could be controlled by a single commander— three to four miles at most. This in turn meant that the number of troops on each side very rarely exceeded 100,-000, a limit that, as mentioned above, had already been reached by Hellenistic times. Indeed, whenever Napoleon brought more than 100,000 men into battle, he tended to lose control over some of them—as happened at Jena, when he forgot about three of the seven corps at his disposal. At Leipzig in 1813, 180,000 French troops faced almost 300,000 Prussians, Russians, Austrians, and Swedes, causing the battle to fall into three separate engagements that were hardly related to one another.

During the 19th century all this was to change, especially as the Industrial Revolution began to make its impact felt on the battlefield after about 1830. Following a century and a half of stagnation, small arms began to undergo rapid technological development. First came percussion caps, then rifled barrels, cylindro-conoidal bullets, breech-loading mechanisms, metal cartridges, and magazines. These improvements permitted tremendous increases in reliability, rate of fire, range, and accuracy—as exemplified by the French Chassepot rifle of 1866, which was sighted to 800 metres and was thus theoretically capable of hitting a target at six times the range of the old flintlock musket. Artillery underwent similar development as the old bronze or cast-iron muzzle-loaders gave way to rifled, breech-loading guns made of steel. From the middle of the century, the solid shot and canister that had long formed the principal types of ammunition were replaced by explosive shell, leading to another great increase in lethality and sheer destructive power.

Growing
lethality of
weapons

As might be expected, these developments had a profound impact on tactics, even to the point where the very meaning of battle was transformed. Already during Napoleon's time, presenting a solid wall of flesh to the enemy could result in exceedingly heavy casualties. As a result, some of his later battles—Wagram (1809) and Borodino (1812), in particular—were won by mass butchery rather than tactical finesse. Now, however, such methods became positively suicidal. In order to survive on the battlefield, troops, often acting against their officers' wishes, had to discard their brilliant uniforms, lie down,

take cover, and disperse. As a result, tightly packed formations disappeared or, in cases when they were retained by obtuse commanders, merely led to horrific casualties such as those suffered in Pickett's Charge at Gettysburg in 1863. First in the United States, then in Europe, tactical formations began to dissolve: following the Battle of Königgrätz in 1866, the Prussian chief of staff Helmuth von Moltke expressed concern over the tendency of entire armies to melt into skirmishing lines. The ability of officers to keep their units apart, their men in hand, and their objectives in view declined, if it did not actually disappear. These developments puzzled contemporaries, who came up with the most bizarre ideas as to how to deal with them. In the end, they favoured armies, such as the German one, that adapted to the new circumstances by decentralizing command and making greater use of the individual soldier's initiative.

Insofar as dispersal took place, it caused fronts to grow much longer and less cohesive. From the middle of the 19th century, this tendency was reinforced by the larger number of troops produced by conscription. As battles took up more space, the number of men within a given area declined very sharply. Within each army, fewer troops were actually in action at any moment, giving and receiving fire. This, in turn, caused battles to grow much longer. During the American Civil War, some battles, such as Gettysburg, lasted three days, and one week-long series of engagements became known as the Seven Days' Battles. Since modern weapons permitted fighting at longer ranges, gradually a situation was created where the rear areas of armies could be brought under fire just as well as their fronts. Battles, in brief, ceased to be distinct events that could be well defined in time and place and easily identified by crossed swords on a map. During World War I, it became routine for battles to spread over dozens of square miles and last weeks or even months. And, as aircraft became increasingly effective during World War II, they went far to obliterate the distinction between front and rear—another symptom of the changes brought about by modern technology.

The longer that battles lasted, usually the less severe were the casualties produced on any particular day. Throughout the 18th century until the French Revolutionary Wars, armies had fought at the very most three major battles during a campaigning season, which was normally calculated at 180 days. These were bloody affairs, since a few hours of murderous, eye-to-eye combat could easily produce 20, 25, or even 30 percent casualties. However, post-1870 armed forces used their weapons to fire at each other at considerably longer ranges; they also operated in a much more dispersed manner and very seldom brought all or even most of their forces together at a single point. Hence, although over a period of time losses could be just as heavy, they seldom suffered as intensely in a single battle. To suffer casualties in excess of a few percent of strength in one day, as happened to the British at the First Battle of the Somme in 1916, was an exceptional calamity. It was as if, in an instinctive response to the overwhelming power of the new weapons, the fighting became more prolonged but less intense—there being only so much terror that men could stand.

The power of the defense. The last years of the 19th century witnessed the development of automatic weapons in the form of machine guns. Artillery, too, was revolutionized by the addition of recoil mechanisms, which obviated the need to resight the guns after each round and therefore permitted much more rapid fire. As a result, the infantry, no longer able to survive the storm of steel sweeping the open terrain, was forced to seek refuge underground. The ineffectiveness of charging cavalry was proved by the immense losses it took during the Crimean and Franco-German wars: unable to follow foot soldiers into underground shelters, it languished and finally disappeared altogether. The tactical defense, rendered invisible by the substitution of smokeless powder for black powder, became much stronger than the offense. This development, the first signs of which could already be seen in the 1850s, dominated the South African War (1899–1902) and the Russo-Japanese War (1904–05)—although

most European commanders refused to look facts in the face until the butchery of World War I. During that war, fronts, manned by armies whose troops numbered in the millions, solidified into continuous trench systems that were sometimes hundreds of miles long. Often there were two and even three lines of trenches protected in front by belts of mines and barbed wire hundreds of yards thick. From the rear they were linked to communication trenches, which led into them and allowed reinforcements to arrive without leaving cover.

To overcome a well-entrenched enemy was something that could be achieved, if at all, only by tremendous concentrations of heavy artillery. Directed by forward observers and from balloons and aircraft overlooking the battlefield, artillery fired high explosive, gas, or—ideally, since the two called for different and even contradictory responses—a combination of both. The number of rounds fired could run into the millions; even so, an astute defender needed neither despair nor expose his troops to the physical and psychological effects of a heavy bombardment landing on their dugouts. Instead, leaving only a thin screen to hold the forward line, he could keep his main forces out of the guns' range. As in Wellington's day, the preferred location of such defenses—witness the so-called Hindenburg Line built by the Germans in 1917—was on the reverse slope of a hill or ridge. This denied the enemy observation, complicated his planning, and made it much more difficult for him to register his artillery on target.

In its highest and most developed form, the World War I defensive system consisted of a fortified belt several miles deep. Its main strength was not its continuous trenches but rather its being studded with well-positioned, well-camouflaged strongpoints. So long as the belt held intact, the strongpoints faced forward, bringing fire to bear and acting as observation posts for their own defending artillery. They were, however, also capable of mounting an all-around defense even in the absence of communication with one another and with the rear, thus obstructing the successful attacker as well as delaying and canalizing his progress. Standing ready immediately behind the belt were units (usually the size of regiments, sometimes entire divisions) held in reserve for launching counterattacks. In the German army at any rate, the commanders of such units were often authorized, not to say required, to act on their own initiative without waiting for orders from rear headquarters. The saving of time that was achieved in this way usually permitted local breakthroughs to be quickly repaired, as happened at Cambrai in 1917.

In the face of such defenses, the best-organized attacks were often helpless. Attempts to follow up artillery bombardments by infantry attacking in lines (the method selected by the British at the Somme in 1916) merely led to enormous casualties unequaled in warfare before or since. Later in World War I the Germans, commanded by Erich Ludendorff, developed a new offensive system. The usual daylong and even week-long bombardments were replaced by shorter, more intensive barrages in which gas and high explosive were carefully coordinated and which lasted no more than a few hours. To maintain surprise, no registration rounds were fired, the guns being laid solely by means of mathematical calculation and weather reports. The attacking troops were organized in small, self-contained storming parties. Armed with light machine guns, hand grenades, light mortars, and even some specially designed artillery pieces light enough to be manhandled, they used so-called fire-and-movement tactics. Each subgroup advanced, took cover, and provided the other with covering fire in turn. Like other World War I infantry, the German *Sturmtruppe* suffered greatly from a lack of mobile radio linking them with their own artillery as well as rear headquarters, but, unlike the rest, they were able to overcome this problem to some extent by operating in a decentralized manner, filtering between enemy strongpoints and bypassing resistance in order to penetrate into the rear.

Regarded from a purely tactical point of view, the German methods were very effective. Having proved their worth at Caporetto in 1917, during the great offensives launched in the spring and early summer of 1918 the Ger-

mans repeatedly succeeded in driving through British and French defenses. Ultimately, however, they were brought to a halt by the inability of logistic services to follow up over the devastated terrain. Deprived of even the most elementary supplies, the attacking troops were forced to resort to looting and soon lost their cohesion. Sooner or later the breach they made was sealed by the other side's reserves, leaving them stranded in the salient they themselves had created and thus exposed to counterattacks on three sides. It should be added, though, that the World War I offense stood a much better chance of succeeding in theatres other than the Western Front, including, in particular, Poland, Russia, and Palestine. In those theatres modern weapons—especially heavy artillery, which could not be brought up over underdeveloped transportation networks—were often less dense on the ground. Hence attacks could succeed, and in some circumstances even cavalry remained effective.

Another offensive weapon destined to have a great future was the tank. The idea of employing armoured vehicles on the battlefield was not new, dating back at least as far as Leonardo da Vinci (before 1500), but they first appeared on the battlefield in 1916 at the Somme. World War I tanks were either "male" or "female"; that is, they were armed either with cannon up to 75 millimetres in calibre or else with machine guns. They could drive through wire and cross trenches (sometimes by dropping fascines into them), crush or neutralize strongpoints, lay smoke screens, and serve as mobile cover for the infantry to follow. During the last two years of the war they were often employed in all these roles, sometimes with success (as at Amiens in August 1918) and sometimes without. Success often depended on numbers: tanks operating individually or in small groups, it was found, did not have sufficient shock effect. Their armour, only 12 to 16 millimetres thick, could be defeated by a determined defender employing field artillery, heavy machine guns, or even special rifles firing heavy ammunition. On the whole, then, early tanks were essentially motorized versions of ancient siege machines. Given their short range, low speed, and general clumsiness, they were suitable for little else.

The armoured offensive. In the decade following World War I, some armies accepted the superiority of the defense as a critical characteristic of modern warfare—a train of thought that caused the Maginot Line to be constructed in France. Elsewhere, there was a lively debate concerning the best way to break through defensive belts. Aside from air power, two principal solutions were put forward. One, which stressed continued development of the light infantry tactics that had achieved partial success in World War I, found particular favour in Germany, where the *Reichswehr* was prohibited from developing and deploying heavy weapons and where the chief of staff, Hans von Seeckt, built an elite army that would cut through the defense "like a knife through butter." The other solution, particularly popular in Britain, was armour: improved tanks, operating much like the heavy cavalry of old, were supposed to overcome the defense and restore mobility to the battlefield. There were even visions of armies consisting entirely of tanks.

After 1935 the leading theoreticians reversed their positions. Some of the original proponents of tanks, notably the influential British strategist Basil Liddell Hart, now concluded that the defense had become much the stronger form of war and that armoured offensives would come to grief against a properly organized enemy. In Germany, by contrast, faith in the offensive was never lost, although Adolf Hitler encouraged progressive officers to forsake light infantry and take up tanks—in effect taking the tactical principles pioneered by light infantry in World War I and developing, modifying, and adapting them to armoured warfare. As a result, the *Panzerwaffe* was an elite force that grew out of the cavalry rather than the infantry, but it retained many elements of the latter's mode of operations, including an emphasis on interarm cooperation, a decentralized system of command operating within an exceptionally disciplined framework, and a penchant for outflanking and bypassing obstacles rather than confronting them head on.

Figure 4: *The armoured division in North Africa, 1941.* Typifying the fast pace and large scale of modern conventional warfare, tanks roll past destroyed artillery and race toward a new engagement barely visible in the distance. Drawing by K. Ceasar. In the German Armour School, Munster, Ger.
Lt Col George Forty

On a higher level, the Germans saw tanks not as simple siege machines but as fit for playing a strategic role. In World War II, the sequence of the previous war was reversed in that making an initial breach in the enemy's defenses was usually entrusted to the artillery, infantry, and engineers, supported by dive-bombers when the opportunity offered. Once the breach had been made, tanks, accompanied by motorized and later mechanized infantry, poured through. Relying for reconnaissance on the Wehrmacht's ubiquitous motorcycles, they fanned out in the enemy's rear, overran his headquarters, cut his communications, and brought about his collapse by virtue of confusion as much as anything else. To ward off counterattacks against flank and rear, reliance was placed both on the Luftwaffe and on excellent antitank artillery (from 1941 some of the latter was mounted on tracked, self-propelled undercarriages, thus creating what were effectively turretless tanks useful both for tank hunting and for close support). To permit all these various troops to cooperate with one another, the Germans added signal troops (they were the first to develop a comprehensive mobile communication system based on two-way radio) as well as a headquarters. Thus, they created the first armoured divisions, which from 1940 became the very symbol of military might.

Changes in command. As armoured tactics developed, the position of the commander as well as the role he played in battle changed. Primitive and ancient commanders, with the partial exception of Roman ones, normally took an active part in the fighting. They and their medieval successors delivered and received blows themselves as a matter of course, with the result that they were sometimes wounded, as was Alexander the Great, or taken prisoner, as was Francis I of France at Pavia in 1525. However, during the second half of the 16th century bureaucratic means of government began to take over from feudalism, and changing social mores no longer required that rulers fight in person. The switch from hand weapons to firearms itself permitted better control, causing commanders to put more emphasis on directing combat and less on participating in it. Increasingly they were to be found not in the midst of their troops but well to the rear, standing on a hill. After about 1650 they could use a "spying glass," or telescope, in order to distinguish their units (newly clothed in uniform) from one another and from the enemy. To communicate their intentions to subordinates they would rely on messengers—and indeed it was in this period that the modern aide-de-camp made his appearance.

An important 19th-century development consisted of electric communication in the form of the telegraph and, later, the telephone. Replacing mounted messengers with the infinitely faster wire made it possible to exercise active command even with armies very far apart and, equally

The first use of tanks

Blitzkrieg

significant, with armies distant from headquarters, located far to the rear. As a result, distances between field commanders—to say nothing of commanders in chief—and their troops tended to increase until they could be measured in miles and even tens of miles. Commanders and their staffs left the field for the office, getting their information by reading reports and bending over maps rather than peering between their horses' ears. After 1860 the old expression *coup d'oeil*, which implied a commander "casting a glance" over the battlefield and making his decision on the spot, was replaced by "estimate of the situation," with its connotation of cooler deliberation. The point was reached when, during World War I, commanders from division level up seldom visited the front; nor would the six-foot-deep trenches, screened by concertina in front, have allowed them to take a good look at the enemy even if they had visited it. Moreover, wired communication systems were basically immobile, and efforts to protect them by burying them in the ground tended to make them even more so. In this way they acted as another factor that favoured the defense over the offense.

Radio
communi-
cation As commanders came to rely on the wireless communications developed between the world wars, they were able to forsake their headquarters and take to modified tanks, half-tracks, trucks, or even jeeps, which were distinguished from other such vehicles merely by the forest of antennas that they carried. In this way they were able to see the front for themselves and provide leadership at decisive points, all the while keeping in touch with other sectors of the front as well as rear headquarters. In his memoirs, Dwight D. Eisenhower, supreme commander of the Allied forces during World War II, wrote that soldiers usually welcomed his visits because these meant that there was no danger in sight; but other commanders in that conflict, such as Heinz Guderian, Erwin Rommel, George S. Patton, and even Bernard Montgomery (while still merely an army commander) operated in a very different manner from their World War I predecessors. Instead of ensconcing themselves in châteaus, they roamed all over the theatre of war, not seldom taking to the air and covering hundreds of miles in a single day. Regarded from this point of view, radio helped to reverse a secular trend that had been unfolding for centuries, enabling those who knew how to use it to bring about a revolution in command. But for this, modern armoured operations as pioneered in World War II would have been impossible.

Limitations of the tank. Air forces assisted armoured formations during World War II by providing reconnaissance, interdiction, and close support, as well as putting down airborne troops in front of advancing spearheads when the occasion demanded. Between 1939 and 1942, this method of making war led to brilliant victories equal to any in history. Later, though, it became increasingly clear that there were certain limits to the armoured offensive. Since railways were too inflexible for the purpose, armoured divisions depended on motor convoys for the bulk of their supplies. These convoys themselves made extraordinary demands for fuel, maintenance, and spare parts, with the result that even the most carefully planned, brilliantly led armoured thrusts tended to lose momentum once their spearheads had reached 200 or 250 miles from base. Such an operational reach sufficed to bring down medium-size countries such as Poland and France but not a continent-size country such as the Soviet Union, which was also distinguished by a terrible road system. When the attacker did not enjoy air superiority, as often happened to the Allies before 1942 and to the Germans after that year, the logistic "tails" on which blitzkrieg tactics depended proved very vulnerable to attack by fighter-bombers. Occasionally, as at 'Alam al-Halfa' in 1942 and again during the German counterattacks in Normandy in 1944, air power was able to halt armoured thrusts almost on its own.

Moreover, tanks, originally conceived as offensive instruments, turned out to be at least equally useful on the defense, especially when dug into the ground in "hull-down" positions and deployed with other weapons and field fortifications such as antitank ditches, mines, and barbed wire. Such a combination presented almost insuperable obstacles to the attacker, whose forces would be caught in a maze, cut into penny packets, and lured into killing grounds. Also, as other countries built up their armoured forces in imitation of the Germans, great tank-to-tank battles sometimes took place; but even here the visions of theorists such as J.F.C. Fuller, who had predicted all-tank armies maneuvering against each other like navies at sea, were seldom, if ever, realized. Even in North Africa, with Combined-
arms
warfare its absolutely open terrain, victory usually went to the side that better knew how to combine armour with other arms such as artillery, antitank artillery, infantry, and, paradoxically, the very engineers whose efforts armour had originally been designed to overcome. From at least 1942, combined-arms warfare became the order of the day, and it remained so for decades to come.

Finally, the tank was not suited for every kind of terrain. Like the cavalry of old, armoured warfare was most effective in broad, open plains like those of northern France, the western Sahara, and southern Russia. In mountainous, forested, swampy, or built-up terrain, the role that tanks could play was necessarily limited, both because of diminished trafficability and because there was insufficient room for them to deploy. Though there were exceptions (witness the brilliant German stroke through the Ardennes in 1940), often tanks were of no use at all—or else they were reduced to supporting the infantry, as happened in Italy and, later, Korea. Since the tanks' rotating turrets had to absorb the recoil of their guns, these were usually smaller in calibre than ordinary field cannon, so that, employed as artillery, tanks were costly and only moderately effective. Thus, armoured warfare was able to achieve its full potential only in certain theatres. In many others, including Southeast Asia and the Pacific, the role of tanks was more limited, and the old combination of infantry and artillery, now also supported by the air force, usually prevailed.

From conventional war to terrorism. *Nuclear weapons.* On Aug. 6, 1945, the first atomic bomb was dropped on Hiroshima, Japan. From this point, all warfare was destined to be overshadowed by nuclear weapons, devices so powerful as to turn even the mightiest conventional forces into negligible, almost risible, quantities. In theatres where nuclear weapons were present in numbers, such as Europe and Korea, conventional warfare was brought to a dead halt. All attempts to devise ways for fighting in a nuclear environment came to nought, so that the preparations made for it (for example, in the Western doctrine of flexible response) took on a make-believe character and were forced to proceed as if nuclear weapons did not exist. As the strategic nuclear forces of the principal military powers neutralized one another, it was only among—or against—small, unimportant countries that war could be carried on more or less as before. Even then, after about 1970 it became clear that any country in possession of the industrial, scientific, and logistic infrastructure needed to build strong conventional forces would also be able eventually to develop both the bomb and the delivery vehicles it required.

Continued growth of military technology. In spite of its many disadvantages, as listed above, the armoured division continued for several decades following World War II as the very symbol of military might. Immense fortunes were invested in developing, producing, and deploying successive generations of fighting vehicles, especially tanks. On the whole, the weight of tanks, their engine power, and the calibre of their guns trebled between 1940 and 1985, although there were considerable variations in the balancing of armour, armament, and propulsion. The new models incorporated numerous novel features such as stabilized turrets, electronic fire controls, and automatic damage-suppression systems. Nevertheless, in the end tanks remained recognizably what they had been before.

The development of other major weapon systems tended to progress pari passu with that of tanks—and indeed many of them were specifically designed to accompany, assist, or counter them. In order to keep up with their tanks, the most advanced armies became completely motorized. As vehicles for transporting troops, trucks were replaced by armoured personnel carriers; these gave way in turn to armoured fighting vehicles, from which troops

could fight without dismounting and some of which were almost as heavy and expensive as tanks. In the rear services, horse-drawn vehicles, which in both the Soviet and German armies had still been in the majority until 1945, disappeared altogether. Consequently, with the bulk of supplies still carried by trucks, the dependence of post-World War II armies on roads was as great as, and possibly greater than, that of their predecessors.

Missiles

Besides fielding more powerful tanks, troop carriers, and artillery tubes, post-1945 ground forces also introduced entire families of weapons that were new and unprecedented. Among the earliest were guided antitank missiles, which entered production during the late 1950s but came into their own only with the Arab-Israeli War of October 1973. Short- and medium-range surface-to-surface missiles extended the range of artillery, which was itself increased by providing rounds with added rocket propulsion. Of the missiles, those designed for attacking tanks at short range (two miles or less) proved most effective, forcing armoured divisions to reorganize themselves in order to make possible still closer cooperation between tanks and other arms. Contrary to original hopes, however, they did not bring about either considerable savings in ammunition or relief to logistic systems, the reason being that the standard response to them was to cover every place from which they might be launched with suppressive fire. By and large, the other surface-to-surface missiles were insufficiently accurate, or their warheads too small, to play a decisive role against opposing forces in the field.

In addition to the traditional high explosive, the various new missiles were provided with guidance and homing systems and carried new and powerful warheads such as cluster bomblets and fuel-air explosive. Other missiles were designed for entirely new tasks, such as rapidly scattering large numbers of minelets in front of an advancing opponent. Such tasks presupposed very accurate information on the movements of an opponent who would still be rather far away and, presumably, capable of rapid movement. To provide such information in so-called real time, growing reliance was placed on electronic sensors and remotely piloted vehicles (RPVs). After becoming familiar in the Vietnam War, where they failed to penetrate the triple-canopy jungle, RPVs became suddenly famous after successful employment by the Israelis in Lebanon in 1982. Launched from mobile platforms and operated by units down to the division level, subsequent generations of RPVs were capable of carrying out surveillance, target acquisition, damage assessment, electronic warfare, and even attacks on enemy radars (when provided with homing devices and explosive warheads).

Close air support

As the jet engine replaced the piston engine in the 1950s and '60s, most aircraft became too fast and unmaneuverable to provide effective close support to ground forces. At the same time, the power of antiaircraft defenses, in the form of missiles and radar-guided, multiple-barrel automatic cannon, increased by leaps and bounds. The Vietnam War and the 1973 Arab-Israeli War demonstrated, each in its own way, the limits of air power in the tactical role, and the 1982 Israeli invasion of Lebanon, in which the Israeli air force won a spectacular victory in the sky without decisively affecting the ground battle, provided even stronger proof. Accordingly, there was a tendency to equip aircraft with long-range guided weapons that would enable them to "stand off" from antiaircraft defenses, and these weapons were used to great effect against Iraq in 1991 in the Persian Gulf war. For close support, increasing reliance was placed on smaller, more agile attack helicopters. The first massive use of helicopters in the air-to-ground role was in Vietnam, where the enemy was generally much too small and dispersed to be effectively tackled by faster craft. Machines armed with guns and missiles specifically designed for "tank busting" entered service during the mid-1970s.

The end of technological warfare. Individually, the heavy weapons developed and fielded after 1945 were much more powerful than their predecessors and, thanks to their electronics, capable of hitting faster-moving targets at longer ranges and with greater accuracy. Nevertheless, and in spite of endless talk about the revolutionary changes

in warfare brought about by these new arms, the operational art on land stagnated. For 40 years after World War II, the greatest problem confronting Warsaw Pact armies was how to imitate the Wehrmacht and mount a super blitzkrieg aimed at overrunning Europe; simultaneously, the greatest problem confronting the North Atlantic Treaty Organization was how to stop such a blitzkrieg in its tracks. As a result, the great military theorists who pioneered the doctrines of armoured warfare during the 1920s and '30s had no successors of similar stature. Their place was taken by nuclear strategists, whose most important concern was not how to fight a war but how to prevent it from breaking out.

In fact, after 1945 there were only two successful blitzkriegs against worthwhile opponents. The first took place in the Arab-Israeli War of 1967; not accidentally, this saw the use by both sides of many tanks, half-tracks, artillery, and other weapons taken straight out of World War II. The second blitzkrieg was launched at the end of the Persian Gulf war of 1990–91, when the Iraqis, after weeks of saturation bombing, put up so little resistance that only four of the most advanced U.S. tanks were disabled—and none by enemy fire. The October 1973 Arab-Israeli War, by contrast, pointed to the limitations of armoured forces, which suffered high casualties when employed against determined infantry carrying modern antitank weapons or when used as offensive instruments against other armoured forces.

Limitations of armoured warfare

All in all, military forces in the second half of the 20th century were characterized by an unprecedented faith in, and drive for, technology. More and more, land armies deployed their firepower—and their money—in the form of heavy, motorized, crew-operated weapon systems. If only because of their greatly extended ranges, these systems increasingly relied on electronic means for target acquisition, identification, range finding, and aiming. Indeed, the time was to come when the number and quality of electronic gadgets employed by armies became the best possible index of their modernity. However, such devices and their attendant computers operated best of all in simple environments, such as sea and air; in some ways, the most favourable environment of all was outer space, where there was nothing to fight about. Conversely, the more complex the environment, the less reliable and useful modern electronics became, since very often they either gave out the wrong signal or none at all.

The net effect of these factors did not take long to make itself felt. While it became clear that modern armies could inflict enormous attrition on each other, their reliance on long-range, crew-operated, and motorized heavy weapons (and the electronics that these incorporated) also brought about a decrease in those armies' ability to fight opponents that did not resemble themselves—particularly opponents that deliberately chose to operate in complicated terrain, including above all civilian populations and their habitats, communication networks, and means of production. As the Germans in World War II had already learned, in such environments modern weapons, by virtue of their very power, did more harm than good. Panzers and dive-bombers could slice through fronts, defeat armies, and overrun countries, but holding those countries down in the face of hit-and-run guerrilla and terrorist attacks was a different matter altogether and could be achieved, if at all, only by old-fashioned infantry.

After 1945 a similar experience was had by virtually every modern army belonging to both developed and developing countries: fighting against organizations other than regular, state-owned armies, they almost always went down to defeat. Technological superiority did not help the French prevail over the Viet Minh in Indochina or the fellaghas in Algeria any more than it enabled the British to defeat Irgun Zvai Leumi in Palestine, the Mau Mau in Kenya, or EOKA in Cyprus. The Soviets in 1979 and the Israelis in 1982 found it easy to overrun Afghanistan and Lebanon, respectively; however, their initial victories proved not so much useless as irrelevant to the final outcome of these wars. The Cubans in Angola (1975–91), the South Africans in Namibia (1975–89), the Indians in Sri Lanka (1987–90), and even the tough Vietnamese in Cambodia (1979–

89) all learned the same lesson. In most such cases the insurgents scarcely deployed anything heavier than anti-tank rockets, machine guns, and light mortars, but often they did not even have those; yet their tactics forced the regular armies to withdraw, sometimes after driving them to the point of complete breakdown, as happened to the Americans in Vietnam. The limitations of conventional forces, their weapon systems, and their methods of making war were highlighted by the fact that conflicts of this kind were far more numerous than conventional ones during the post-1945 period. They also produced by far the most important political results, to say nothing of the number of casualties.

Caught between nuclear weapons and guerrilla warfare

As the 20th century approached its end, there were abundant signs that large-scale, interstate, conventional operations of war had been caught in a vise between nuclear weapons on the one hand and low-intensity operations on the other. In places where nuclear weapons were present—even where the threat was undeclared, as between India and Pakistan or between Israel and its immediate neighbours—such operations were much too dangerous to be attempted. In other places (actually the great majority), where the threat came not from state-owned armies but from other types of organizations with no clear territorial base, conventional warfare was largely useless. Low-intensity warfare had no room for tactics as normally understood and in fact seemed likely to cause them to disappear—that is, to merge with politics and propaganda on the one hand and with terrorism and intimidation on the other. This meant that, even as vast sums continued to be spent on modern conventional weapons and the armies fielding them, the kind of war for which those armies and those weapons were designed seemed to be coming to an end and might, indeed, already have ended. (For further discussion, see below *Guerrilla warfare*.)   (M.v.C.)

Naval tactics

FUNDAMENTALS

Being the activities of battle itself, tactics are conceived and executed at the literal and metaphoric centre of war's violence. Tactical science is an orderly description of these activities, and tactical art is the skill required to carry them out in combat.

The search for constants. It should be said that, in order to achieve victory, willpower and courage must always accompany tactical art and science and often dominate the outcome of battle. These qualities are not tactics, but they are related to tactics in the way a sound decision is related to the resolution with which it is implemented. There is no finer example than Horatio Nelson. In the Battle of the Nile (Aug. 1–2, 1798), not only were Admiral Nelson's tactical decisions brilliant, but he had so imbued his captains with his thinking that, when they saw a chance for surprise by attacking the disengaged side of the French fleet, they were quick to seize it and gain a decisive advantage (see Figure 6). Still, their decisions only established the basis of that great victory, for the French

fought with desperation, and it took hard fighting by British tars, inspired by Nelson's charismatic leadership, to fulfill the promise of victory.

In a similar manner, new technology is not tactics, but it may have a decisive effect in both altering the face of battle and affecting its outcome. Navies put special emphasis on warships and aircraft. It is well said that on the ground men are served by their weapons while at sea weapons are served by men. Lest his readers be too enamoured of élan and fighting spirit, Rear Admiral Bradley A. Fiske used a telling example in *The Navy as a Fighting Machine* (1916). He pointed out that in the American Civil War the Confederate ironclad *Virginia,* with 10 guns, handily defeated the Union sloops-of-war *Congress* and *Cumberland,* which carried a total of 74 guns. One day later the Union's *Monitor,* carrying two guns in a turret, fought the *Virginia* to a standstill. Courage and resolve were powerless against progress and armour.

The American naval strategist Alfred Thayer Mahan made perhaps too much of the influence on tactics of technological progress. In his seminal *The Influence of Sea Power upon History, 1660–1783* (1890), he wrote that, due to new fighting systems, "from time to time the structure of tactics has to be wholly torn down but the foundations of strategy so far remain, as though laid upon a rock." Mahan appreciated the utility of naval history for the discovery of strategic constants—that is, principles of strategy that have remained valid throughout technological change. Tacticians, on the other hand, are conscious of tactical constants as well, especially the following: the power of concentrated force (rarely in history has a naval tactician withheld a reserve); the special value of surprise; the abiding need for cohesion brought about by sound command and combat doctrine; the consummate goal of attacking effectively first; and the unique role played by timing and timeliness.

Five constants of naval warfare

The study of trends. Naval officers also study history for its trends, because trends are the only clue as to how tactics are changing and are the best check against the fatal sin of preparing to fight the last war. The trend that has influenced all else in the conduct of naval battle is the increasing range and lethality of naval weapons. Paradoxically, greater lethality has not led a trend toward greater loss of life. The first reason is that, unlike ground combat, the principal aim at sea is to put the fighting machine, not the fighting man, out of action, and modern machines are (thus far) sensitive to damage. Second, it is a longstanding constant that naval battles, once joined, are fast-moving and decisive.

To sketch how the range of weapons has affected naval tactics, a simple structure that describes the processes of combat must be established. First is firepower delivery itself. Second is the scouting process, which gathers information by reconnaissance, surveillance, cryptanalysis, and other means and delivers it to the tactical commander. Third is command itself—or command and control (C^2) in modern parlance—which assimilates the information, decides which actions are called for, and directs forces to act accordingly.

Combat being the activities of force against force, there is a natural antithesis to all three processes described above. First, the effect of enemy firepower is reduced by shooting down the incoming aircraft or missile, by maneuvering to avoid a torpedo, and by ship survivability or "staying power"—that is, the ability to continue fighting after suffering damage. Second, when scouting was accomplished by ships or aircraft flung out ahead of a formation, information denial was accomplished by screening—that is, by flinging out an opposing line of ships and aircraft. Modern ways to confound the enemy's scouting effort are keeping radio silence and jamming his radars, both of which deny him information. Third, enemy C^2 can be confused by deceptive signals or decoy forces. It can also be crippled or delayed by electronically jamming enemy communications.

The seven processes described above—namely, firepower delivery, scouting, C^2, the three countermeasures against them, and maneuver—are the raw materials of naval tactics. To achieve success, they are synthesized into a

The essential elements of naval combat

harmonious blend of action and counteraction. For example, a modern naval screen of ships or aircraft defends a formation both by destroying enemy aircraft or missiles and by denying tactical information. The screen itself may even be so central in importance that it becomes the focus of enemy attack, with destruction of the screen being tantamount to destruction of the force. Thus, the study of naval tactics has become more than the study of formations, firepower, and maneuvers. The increase in weapon range has been paralleled by scouting and the control of forces at longer and longer ranges; these in turn have opened up more avenues to gain information and confuse the enemy's picture by electronic means.

Tactics in the modern era.   The study of tactics has always emphasized actions between fleets that gain or challenge control of the sea lines of communications. That traditional emphasis is retained here, but in the 20th century three other types of combat at sea have demanded greater attention.

War from land to sea and from sea to land.   While navies have always had as their ultimate objective an influence over events on land, aircraft and missiles have extended the range and amplified the influence. Likewise, land-based systems have made their growing influence felt on warships and sea-lanes alike. Putting ground forces ashore from the sea by amphibious landing is an operation that has neither gained nor lost importance since the earliest galley warfare, but modern combined-arms tactics are quite different and require separate attention. A byproduct of the extended range of modern weapons is the greater complexity of joint operations. The reorganization of many armed forces has been in large measure a response to the demand for well-coordinated operations.

Nuclear weapons.   The United States, the Soviet Union, the United Kingdom, France, and China keep a considerable strategic deterrent force at sea in the form of submarine-launched ballistic missiles. The safeguarding or threatening of nuclear submarines has inspired a set of tactics unique in history. These tactics are among each nation's most closely guarded secrets and have never been used in anger, so that all knowledge of them is theoretical, based on mathematical computations, computer simulations, and constrained exercises at sea. This does not mean that such tactics, if ever used, will prove unsound. During the great transition from sail to steam and big gun, keen study by naval tacticians throughout the world developed the sound tactics that were finally practiced in World War I.

Raiding.   War against trade is the war of an inferior navy that cannot compete for command of the sea but that, instead, dispatches raiders to deny the enemy its free use. These tactics of sea denial are those of predator and prey, of hunter and evader, and are as unique from the force-on-force tactics of major sea battles as are guerrilla war tactics from those of decisive land battle. With the maturity of submarines, these tactics have become so important that a separate section is devoted to them (see below *Guerrilla war at sea: the submarine*).

HISTORICAL DEVELOPMENT

In the following examination of the history of naval tactics, a shift in importance between elements of combat will be apparent. In galley warfare, sheer power dominated the outcome, and maneuver of numerous small ships, much as on land, contributed to its concentration. In warfare under sail, great firepower could be concentrated in individual ships, and doctrine, formations, and signal flags were means of controlling the slow-moving, wind-constrained formations. With battleships, steam power gave freedom to maneuver in any direction, and the range of the big guns allowed a concentration of fire from the whole formation. The defensive element came to prominence, symbolized by armour. Tactical decisions had to be made before the enemy was in sight, so that scouting became more evident as a tactical ingredient. Control had to be exercised over much greater distances, which expanded the possibilities of exploiting the means of control, notably through radio direction finding and code breaking.

The growth in the tactical influence of scouting, anti-scouting, command and control, and countermeasures against command and control continued through the era of the aircraft carrier and into the era of the guided missile. These elements have become as important to tactical success at sea as firepower, consuming comparable thought and resources.

The age of galley warfare.   Galleys being relatively unseaworthy, war at sea among the ancients was always near land. Pictures of billowing sails notwithstanding, masts and canvas were stowed for battle, and oars were the means of propulsion. The most destructive weapon was a ram in the bow, which dictated a line abreast as the tactical formation. In the line abreast, two lines of opposing galleys approached each other head on, with the ram of each vessel unobstructed by the ships on either side. Momentum was the key to the ram's destructiveness, so that sprint speed—as much as seven or eight knots (nautical miles per hour, that is, eight to nine statute miles per hour or 13 to 15 kilometres per hour)—was as important as maneuver. Multiple banks of oars afforded speed, and the geometry of their arrangement fascinated naval architect-historians of later eras.

The ram and the line abreast

Major battles comprised hundreds of ships on a side. Battles occurred because of the threat of invasion, so that many armed men were present. These participated as archers or boarders. Rome developed grappling hooks and the *corvus* (a long boarding plank spiked at the end) to secure the victim ship while disciplined legionnaires fought their way on board.

Scouting the enemy formation was a subordinate issue, although contemporary descriptions indicated that formations and maneuvers, showing ingenuity and cunning, played a large part in the outcomes. Since battles were nearly impossible in foul weather, good visibility permitted the deployment of the lines abreast, often in two echelons, much as the commander intended. Descriptions of the battles (and the period was rich in them) were usually couched in the terms of land warfare—such as the routing of a flank, or an attempt to crush by encirclement. Galley tactics were so similar to land tactics that a reserve was actually held back—a practice that ever afterward was regarded in navies as a mistake. An inference cannot be drawn that a commander had tight control of his ships in action, however, and the correct image of a galley battle would be that of a wild melee, with oars smashed, hulls crushed, armour-clad soldiers drowned, losses enormous, and battles decisive with lasting consequences.

The ultimate battle under oar was at Lepanto on Oct. 7, 1571. Fought between a combined fleet of the Mediterranean's Christian nations and the vaunted Turkish navy, this battle was reported in great tactical detail. More than 200 Christian oared vessels met 270 of the Turks' in the Gulf of Patras on the Ionian Sea. By this time, three to five guns were fitted in the bows of galleys, and harquebuses were fired by Spanish soldiers. But, as was usual in galley warfare, the outcome was decided by boarding and hand-to-hand fighting with sword and pike. The Christian fleet under Don John of Austria prevailed in a bitterly contested donnybrook; losses to the Turks were placed at 30,000 killed, against 8,000 among the victors.

The age of fighting sail.   By the middle of the 17th century guns arrayed along the sides of fighting ships were the decisive weapon. Heavy guns required a gun deck and a short, sturdy hull, which were at odds with the galley's requirements of lightness and length. Thus, the shift to sail was a victory of fighting strength over maneuver. Tactically, sailing navies became victims of the wind's whim, but strategically they benefited from nearly limitless range and, compared to the frail galleys, greatly improved seakeeping.

The column, or line ahead, became the logical tactical formation for bringing the most guns to bear. With all the ships of a battle line following one another, their guns could face the enemy line without obstruction. The three Anglo-Dutch Wars of 1652–74 saw the first closely studied battles of sail and gun. In them the column was as much a means for command and control as it was for concentration of fighting force, for as long as a fleet maintained station in line ahead, each ship separated by a

The naval gun and the line ahead

Theoretical tactics in the modern era

scant 200 or 300 yards, cohesion was assured, maneuvers were coordinated, and any malingering by reluctant captains was obvious.

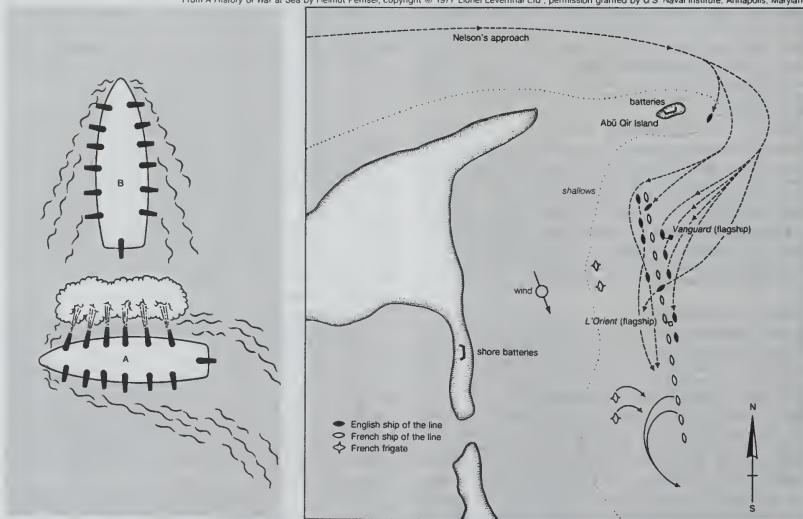
The line was not a formation that permitted the concentration of fire, however, for naval guns in a rolling platform were effectively accurate at only about one-quarter of a mile, and the range for penetrability of shot was even less. In effect, engagements were decided within pistol shot, a battle line being a thin ribbon of death, miles long but scarcely 300 yards wide. When the English fought the Dutch in the 17th century, this was not considered a problem, because the tactics of both sides called for closing with the other aggressively. But in the 18th century their French opponents felt that their strategic interests lay in avoiding battle at close quarters, and in the Anglo-French wars the Royal Navy endured a long period of indecisive actions handicapped by a tactical doctrine so rigidly interpreted by courts-martial as to have become tactical dogma. These *Fighting Instructions,* though soundly conceived when first issued in 1653, were unsuited to this new approach, for the implementing system of signals was unimaginative and constraining. Indeed, the two most admired tactical writers of the day, Paul Hoste and Sébastien François Bigot de Morogues, were French.

Toward the end of the 18th century, the British admiral Richard Kempenfelt began to unshackle the Royal Navy with a better system of signaling. The new freedom of maneuver came finally and forever to be embodied in the tactical genius and personal inspiration of Horatio Nelson, whose matchless victories at the battles of the Nile, Copenhagen (April 2, 1801), and Trafalgar (Oct. 21, 1805) drew the enduring admiration of naval tacticians.

Tactical study during this era concentrated on maneuver. "Breaking the line" of the enemy fleet was one aim, because this broke the enemy's tactical cohesion and made it possible to overwhelm individual ships by bringing greatly superior force to bear on each of them in turn. Popular aims were raking (firing a broadside the length of an enemy ship from across the bow or stern) or doubling (concentrating force by putting ships on both sides of the enemy line; see Figure 6). The most reliable way to concentrate gunfire was to build it into ships vertically by stacking gun decks one over the other. Later tacticians demonstrated analytically what every fighting seaman of the seafaring era knew instinctively: with equal competency exhibited on both sides, not only would a two-decked frigate beat a lighter, one-decked corvette, and a three-decker beat a frigate, but the loser would come away having done very little damage to his bigger opponent. Whence came the big "ship of the line," a three-decked ship that could stand in the line of battle and beat down smaller opponents while surviving to fight again.

The age of steam and big gun. Tactics and technology complement each other, and there is no better period in history for studying their interrelationship than the shift from sail to steam in the 19th century. The shell gun (raised to naval attention during the Crimean War by the Battle of Sinope, Nov. 30, 1853) compelled navies to adopt the iron sheathing of hulls. This pointed the way to all-metal hulls (iron, then steel), which in turn both permitted and demanded as a response the installation of rifled, breech-loaded guns of major calibre. Concurrently, iron boilers and screw propellers made steam propulsion practical and gave great new freedom of maneuver. Navies were unfettered tactically from the wind, but only at the strategic price of having to remain within steaming range of coaling stations.

The sweeping consequences of these and other technological innovations lacked the crucible of war in which to test them, for it was an era of Pax Britannica, with the maritime peace kept by the Royal Navy. The *Monitor* and the *Virginia* (at the battle of Hampton Roads, March 8-9, 1862) marked the short-lived ascendancy of armour and the defense. This led to a brief revival of the ram and to some very speculative tactical concepts that looked outrageous in later days.

But the superiority of defense at sea did not last long. The tactical–technical turning point came from the observation of a few battles in East Asia around the turn of the century and from an often overlooked bit of military technology.


Shell guns and armoured hulls

Figure 6: *The tactics of raking and doubling.*
(Left) In the raking position astern, ship A maneuvers across the stern of ship B and fires a broadside the length of the defenseless ship. (Right) The most brilliant feat of doubling was executed at the Battle of the Nile (Aug. 1–2, 1798). Nelson's fleet, rounding Abū Qīr Island, came upon a French fleet anchored in a line near the shore. Half of the English fleet passed inshore of the French, and the other half remained to seaward. With a light following wind, the English slowly worked down the French line, attacking each ship from two sides. Only four French ships escaped; two were sunk, and the rest were badly damaged.

The battles were those of the Yalu (Sept. 17, 1894), the Yellow Sea (Aug. 10 and 14, 1904), and Tsushima (May 27–29, 1905), in which the gun regained primacy to such an extent that the Russian vice admiral Stepan Osipovich Makarov could confidently write, "A good gun causes victory, armour only postpones defeat." The new technology was fire control, which enabled major-calibre rounds to be placed on target at five, then 10, and ultimately 15 miles.

By World War I the tactical issues were settled. First, big guns would dominate, a burly battleship firing a battery of them in broadside. Second, although armour could "postpone defeat," it was all but powerless against torpedoes; therefore, a destroyer screen was essential to protect the fleet. Third, a fleet cruised in compact formation but quickly deployed in column to fight. Since the opposing fleets would close with each other at a relative 40 miles per hour, a scouting line had to be thrown out well in front to report enemy movements by wireless. Despite the elephantine appearance of a line of battleships, there would not be a moment to lose when the enemy was sighted and no margin for error.

A column of battleships was not like a column of sailing ships. With greater range and improved fire control, gunfire from most of the ships on each side could reach most of the ships on the opposite side, making concentration of firepower by a whole fleet feasible and expected. The advantage was worked out mathematically in what were called the "N-square law" and the "square law of attrition": success would build on itself, so that any small advantage at the outset of an engagement would compound in favour of the superior force. With long-range gunnery, the advantage accrued fleet-wide, not merely ship by ship as in the days of fighting sail.

Crossing the T

A positional advantage could be added to this firepower advantage if the fleet "crossed the T" of the enemy, that is, if its own column crossed in front of the enemy column at a right angle and with the ships at the head of the enemy column within range of its guns. From this position at the top of the T, all the guns of the fleet could fire upon the head of the enemy column, while only the first enemy ships could return fire. This was the raking position sought by an individual sailing ship writ large, for at battleship gunnery ranges the whole force could concentrate successively on each enemy ship as it approached. It was reckoned that in fair weather and good visibility a fleet could destroy an enemy in the capped position in 20 minutes; or, if an enemy of equal strength could be surprised with unanswered fire within effective range for as little as five minutes, he would be demolished with little harm to the victor. There would be no leisurely approach, no chance to recover from a missed maneuver or a wrong turn. In fact, in practice the very swiftness of decision worked against maneuvering to cross the T. Much was made of the successful use of this tactic by the Japanese admiral Tōgō Heihachirō against the much slower Russians at Tsushima, but commanders at sea understood that the fast pace of battle worked against a T-crossing except by accident or surprise.

With one salient exception, there were no unforeseen tactics in World War I. The exception was the ease with which a fleet could be surprised at sea. The Battle of Jutland (May 31, 1916) was fought in great confusion, owing to a fog of smoke from the stacks and guns of 250 ships as well as the sloppy work of the commanders of the two scouting forces. The German commander, Reinhard Scheer, twice had his T capped for lack of visibility; for the same reason, the British commander, Sir John Jellicoe, twice was unable to exploit this, the ideal tactical position.

The lesser engagements of the war were also marked by surprise, but from another source. At one time or another, both the Germans and British broke each other's codes. Special intelligence and attempts to entrap a weaker enemy were rife throughout the war, leading to surprise in each of the battles in the North Sea: Helgoland Bight (Aug. 28, 1914), Dogger Bank (Jan. 24, 1915), and Jutland itself.

The extended range of naval aircraft

The age of the aircraft carrier. Early in World War II the primary instrument for delivering naval combat power became the aircraft carrier. The reason was range: aircraft could deliver a concerted attack at 200 miles or more, whereas battleships could do so only at 20 miles or less. The foremost tactical question during the transition in the 1920s and '30s was whether aircraft could lift enough destruction to supersede the battleship. Into the 1930s skeptics were correct that aircraft could not. But by the end of that decade, engines were carrying adequate payloads, dive-bomber and torpedo-plane designs had matured, carrier arresting gear and associated flight-deck handling facilities were up to their tasks, and proficient strike tactics had been well practiced. U.S. and Japanese naval aviators were pacesetters in these developments.

There was a subordinate tactical question as well: could the enemy be found at the outer limits of aircraft range? The ability to attack fixed targets such as the Panama Canal or Pearl Harbor, and to achieve surprise in doing so, had been amply demonstrated in naval exercises as well as in battle, but finding, reporting, and closing on ships at sea was a greater challenge. Without detracting from the courage and skill of aviators, it may be said that effective scouting was the dominant tactical problem of carrier warfare and had utmost influence on the outcomes of the crucial carrier battles of the Pacific Theatre in 1942: the Coral Sea (May 4–8), Midway (June 3–6), the Eastern Solomons (August 23–25), and the Santa Cruz Islands (October 26). In those closely matched battles the quality of U.S. and Japanese aviators and their planes was virtually on a par. When the United States won, it did so by superior scouting and screening, owing in large measure to air-search radar and to the advantage of having broken the Japanese code.

The command and control structure polished by the U.S. Navy during the war was the third vital component, after scouting and the delivery of firepower. The tangible manifestation of modern C^2 was the Combat Information Center, which centralized radar information and voice radio communications. By 1944 the tactical doctrine of coordinating fighter air defenses, along with the now much strengthened antiaircraft firepower on ships of the fleet, was so effective that in the Battle of the Philippine Sea (June 19–21, 1944) more than 90 percent of 450 Japanese aircraft were wiped out in a fruitless attack on Admiral Raymond Spruance's 5th Fleet.

Circular formation of carrier groups

The new tactical formation was circular, with carriers in the centre defended by an antiaircraft and antisubmarine screen composed of their own aircraft plus battleships, cruisers, and destroyers (see Figure 7). For offensive purposes, a circle allowed a rapid simultaneous turn by all ships in a task group in order to launch and recover aircraft. For antiaircraft defense, the circle was shrunk in diameter as tightly as possible so that each screening ship, by defending itself, helped defend its neighbour.

The new battle paradigm called for a pulse of combat power to be delivered in a shock attack by one or more air wings. Despite every intention, though, air strikes against alerted defenses were rarely delivered as compactly as practiced, nor were they as decisive tactically as naval aviators had expected. In the five big carrier battles, one attacking air wing took out an average of only one enemy carrier. (Viewed strategically, this average, along with losses of aircraft of around 50 percent per battle, was enough to govern the pattern of the Pacific war.) Since it took more than two hours to launch, marshal, and deliver an air strike, it was difficult to attack before an enemy counterstrike was in the air. Successful command at sea depended as never before on effective scouting and communication, because in order to win a decisive battle, in World War II as in all of naval history, it was necessary to attack effectively first.

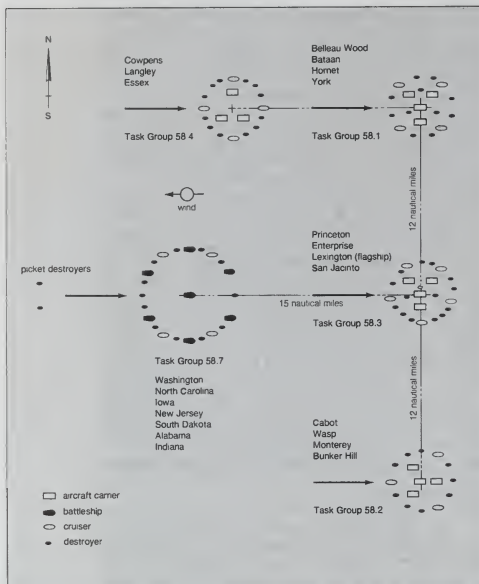
Dominant though it was, carrier-based air power did not control the seas at night. With a modicum of success, the high-quality ships of Germany exploited the hours of darkness, especially during the winter months and in northern waters. In the bitterly contested campaign for Guadalcanal in the fall of 1942, guns ruled supreme at night and very nearly tipped the balance in favour of Japan. Expecting to be outnumbered as a result of the Five-Power Naval Limitation Treaty of 1922, the Imperial Japanese Navy had practiced night tactics assiduously in order, as they supposed, to whittle down the U.S. battle line during its


Figure 7: Circular formations of Task Force 58, U.S. Navy 5th Fleet, Battle of the Philippine Sea, June 1944.
Each task group is arranged in a circle approximately four miles in diameter. This preserves the protective screen when, breaking off a westward pursuit of the Japanese fleet, the ships turn east, into the wind, so that aircraft carriers can launch their aircraft.

After S.E. Monson, *The Two-Ocean War* (1963), Little, Brown and Company

not penetrate the sure American defenses. Nevertheless, during the three-month campaign for Okinawa (April–June 1945) the U.S. Navy lost 26 ships and suffered damage to 164 more—this time to Japanese kamikazes (suicide pilots) flying out of airfields in Japan. The pilots who flew these one-way missions were delivering, in effect, human guided missiles. Kamikazes showed that missiles could, on sufficient occasion, get through otherwise impenetrable defenses. The missile-guidance technology exhibited in the late stages of the war in Europe indicated that missiles would be the kamikazes of the future. And the atomic bomb offered the ugly threat of "one hit, one kill" at sea.

The age of the guided missile. At the end of World War II the supremacy of the U.S. Navy was as pronounced as that of the Royal Navy in the 19th century. With no enemy battle fleet to fight, it staked out the classic role of dominant navies throughout history—projecting its influence over land. Carrier-based aircraft, nuclear missile-carrying submarines, and amphibious-assault units extended that influence greatly. While the U.S. Navy served to link the North Atlantic Treaty Organization (NATO) across the Atlantic, its carrier-centred battle fleet stood ready to deliver sea power over the land. The principal opposing navy, that of the Soviet Union, was configured to challenge NATO's sea link and to confront U.S. aircraft carriers. The result was a new, asymmetrical tactical environment: a surface fleet facing a "fleet" composed mainly of submarines and land-based aircraft.

On a smaller scale than the U.S.-Soviet naval competition, the Falkland Islands War between the United Kingdom and Argentina in 1982 exhibited the tactical environment of sea-based forces fighting land-based forces in the guided-missile era. In this, the only extended naval campaign after World War II, were observed several modern influences on naval combat. First, submarines were formidable weapons, not only in the sinking of an obsolescent pre-World War II cruiser (the *General Belgrano*, formerly the USS *Phoenix*) by a nuclear-powered attack submarine (HMS *Conqueror*) on May 2 but, less obviously, in the harrying of the whole British fleet by one Argentine diesel-electric submarine. Second, the nature, if not the full extent, of the threat of modern air-launched antiship missiles was seen in two Argentine attacks, first against the destroyer HMS *Sheffield* (May 4) and then, after penetrating fleet defenses, the supply ship *Atlantic Conveyor* (May 25). Also, a land-to-sea missile struck and damaged the destroyer HMS *Glamorgan* (June 12), presaging more strikes from land in future maritime wars. Third, the British relearned lessons of damage control and ship survivability, while the Argentines found that aircraft armed only with unguided bombs were outclassed by ships with surface-to-air missiles. Fourth, and perhaps most fundamental, both sides saw the crippling effect of inadequate scouting, for both were without first-line sea-based air surveillance. Both had to manage with makeshift sources, such as picket submarines and commercial aircraft for conducting reconnaissance.

Despite the opposition, the British put forces ashore, maintained sufficient control of the airspace, and kept open the very long lines of supply, and this enabled them to retake the islands. A hasty prediction, made by some modern tacticians, that surface warships would be driven from the seas by modern missiles, did not prove true. Indeed, in the Falklands conflict, the recorded history of sea battles was reaffirmed. By their very nature, sea battles, once joined, still tended to be fast, deadly, and decisive. The commander of a fleet, always the most expensive component of an armed force, might, as Winston Churchill said of Jellicoe at Jutland, lose his ships and the war in an afternoon.

In response to growing weapon range, the collection and delivery of tactical information continued to grow in importance and consumed more manpower and facilities. Radar and electronic intelligence satellites, over-the-horizon radars, large surveillance aircraft, and electronic signal collectors of utmost sophistication were all manifestations of this trend. These scouting devices had their antitheses in electronic jammers and countermeasures—in effect, antiscouting systems.

Modern naval warfare at the Falkland Islands

Electronic scouting

slow march west across the Pacific. Having developed the matchless Long Lance torpedo, they installed it liberally in light cruisers and destroyers and developed tactics that would hurl a barrage of the long-range weapons in the direction of the enemy line—at the same time taking care not to expose the beams of their own ships to a counterstroke. Standard U.S. doctrine, on the other hand, called for fighting in column, employing guns as the primary weapon; the advantages that should have accrued to the Americans at night from superior radar were largely squandered. Between August 1942 and July 1943, in the cruiser–destroyer battles of Savo Island, Cape Esperance, Tassafaronga, Kula Gulf, and Kolombangara, Japanese night tactics prevailed. Not until mid-1943, with tactics attributed to Captain (later Admiral) Arleigh Burke that exploited the radar advantage in full, did the U.S. Navy redress the balance.

Still, naval aircraft were the weapons of decision. Although the duels of the great carrier fleets received more attention, air strikes from sea to shore were as crucial in securing control of the seas. Strikes by the British at Taranto, Italy (Nov. 11, 1940), by the Japanese at Pearl Harbor (Dec. 7, 1941), and by the Americans in the South Pacific at Rabaul (Nov. 5 and 11, 1943) and Truk (Feb. 17–18, 1944) were important to that end as were the more sensational fleet engagements.

Also, in 1944 and 1945 the U.S. 3rd and 5th fleets, 27 fast carriers strong, took the war successfully against entire complexes of airfields in Formosa (now Taiwan), the Philippines, and Japan itself. A traditional tactical maxim, "Ships do not fight forts," was suspended for the duration of the war.

In the closing days of the war in the Pacific, the Battle of Okinawa served to indicate the nature of future combat at sea. By that time the U.S. Navy had reduced the Japanese Navy to impotence, and manned aircraft could

In theory, modern communications have permitted the coordinated delivery of missiles or air strikes at great ranges from vessels in dispersed formations, and the three components of naval combat power—firepower, scouting, and C^2—can be highly dispersed. The major navies of the world, however, have continued to build aircraft carriers and cruisers, indicating a reliance on concentrated battle fleets and on strong defenses rather than dispersal to avoid destruction. The tactical value of concentrated as opposed to distributed power will ultimately depend on whether the historical trend observed above—that is, the growing range and lethality of naval weapons—continues. Battleships delivered salvos of gunfire in a continuous stream of destructive power, and the tactical effect was the N-square law of accumulating advantage. An aircraft carrier delivered a pulse of striking power that, if successful, destroyed about its own weight of the enemy. The classic naval tactic of attacking effectively first was vital. The question of the guided-missile age is whether one ship armed with missiles can sink more than one of the enemy, in spite of the enemy's defenses and ability to absorb punishment. If that is now the case, attacking first will be everything. Missiles that outrange the enemy's will be valuable, but even more valuable will be a compatible scouting system that detects and tracks the missiles close enough to their moving targets for the missiles' terminal guidance systems to lock onto them.

The swift naval engagements of the Arab-Israeli War of October 1973 are enlightening. In that war Syrian and Egyptian Osa- and Komar-class gunboats were armed with Russian-made SS-N-2 missiles, which outranged the Gabriel missiles carried by the Israeli Saar boats. Both fleets were small in numbers and size, but speedy. Based on relative missile range and the obvious sufficiency of firepower on both sides, the Arab boats should have struck first and won handily. The Israeli Navy, however, had recognized its disadvantage and had developed tactics that emphasized better scouting and C^2 as well as the use of chaff to deflect and neutralize the homing mechanisms of incoming missiles. This superior combination won decisively for them against both opponents. Therefore it could not be concluded that the advantage on paper of highly destructive and potentially decisive long-range missiles would win unless it was coupled with good sensors, modern C^2 systems, expert command, and sound training.

Guerrilla war at sea: the submarine. When submarines first went to sea early in the 20th century, they were immediately recognized as an extraordinary threat to surface ships. By World War II they were so effective against warships that they sank nearly as much aircraft carrier tonnage as was sunk by aircraft. Postwar attack submarines, nuclear-powered and armed with missiles and more advanced torpedoes, now pose an even greater threat to surface warships.

In both world wars, submarines were also a serious threat to merchant shipping. In World War II, German U-boats nearly severed the lifelines to Great Britain, U.S. submarines successfully isolated Japan by nearly wiping out its merchant fleet, and, in the Mediterranean, British and Axis submarines vied in attempts to cut their opponents' communication with North Africa.

Solo operation of the submarine

Barring a brief period in 1942–43, when U-boats operated successfully in so-called wolf packs, submarines have always been solo performers, relying for successful attack on concealment and surprise rather than concentration of force. These tactics, quite different from fleet actions, are akin to guerrilla war at sea. The submarine stalks its prey while the target—a warship, merchant ship, or convoy—seeks clues as to its presence in order to take evasive action. Simultaneously, antisubmarine forces—destroyers, maritime patrol aircraft, or helicopters—are predators and submarines the prey. The tactical competition between the two is all search and screening, deadly hide-and-seek, for when the submarine closes, its target can do naught but try to escape the blow, and when antisubmarine forces localize a submarine, no help will come and it will either have to fight like a cornered beast or go silent and try to slip away.

If submarines were able to protect sea lanes from attack, including air attack, then they would be serious candidates to succeed the aircraft carrier as the capital ship of the missile era. But as soloists their role has remained that of sea denial, not sea control, that of spoilers rather than champions of sea power. They are the latest in a long line of raiders of the deep, carrying on a tradition of isolation and stealth that began in the 16th century, when the English privateers Francis Drake and John Hawkins seized treasure ships at sea and raided Caribbean possessions in the teeth of the Spanish navy. Later, in the American Civil War, Confederate raiders such as Raphael Semmes in the *Alabama* harried Northern shipping despite the overwhelming superiority of the Union navy.

To the modern mind, a convoy has become a group of merchant ships protected against submarines. But, beginning in the age of fighting sail, there was a long tradition of protecting convoys against surface raiders, called "cruisers." In *Some Principles of Maritime Strategy* (1911), Sir Julian S. Corbett sorted out the separate roles of the battle fleet and the cruisers: the former established control of the seas by its concentrated presence or in a climactic battle; the latter either struck at lines of communication or attempted to fend off other raiders by operating alone or in small detachments. Corbett also traced the influence of long-range radio communication and predicted that this development would allow navies to bring such a swift concentration of superior power that the utility of surface raiders would come to an end. That he was right was proved by the fate of such surface raiders of World War II as the German battleship *Bismarck,* which was sunk by an overwhelming combination of bombs, naval guns, and torpedoes.

Corbett fully appreciated the major role submarines would play against capital ships, but he did not grasp the extent to which submarines would become the cruisers of the future. Indeed, submarines have become the biggest threat to commerce, ahead of mines and aircraft. In addition, they are at or near the top of the list of effective killers of submarines. Guerrilla war is therefore the apt term for submarine warfare. The battle tactics are dispersion, surprise, strikes where the enemy is weak and unprepared, disappearance into the vastness of the ocean, and a continuing erosion of enemy morale and dilution of his resources.   (W.P.H.)

Air tactics

THROUGH WORLD WAR I

Powered aircraft were first used in war in 1911, by the Italians against the Turks near Tripoli, but it was not until the Great War of 1914–18 that their use became widespread. At first, aircraft were unarmed and employed for reconnaissance, serving basically as extensions of the eyes of the ground commander. Soon, however, the need to deny such reconnaissance to the enemy led to air-to-air combat in which each side tried to gain superiority in the air. Fighter planes were armed with fixed, forward-firing machine guns that allowed the pilot to aim his entire aircraft at the enemy, and the effective range of these weapons (no more than about 200 yards) meant that the first aerial combat took place at very short range.

Origin of fighter tactics

By the second year of the war fighter tactics emerged on all sides emphasizing basic concepts that, with modification, remained applicable through the jet age. First was the surprise attack; from the very beginning of aerial warfare in World War I, "jumping" or "bouncing" unsuspecting victims accounted for more kills than did the spectacular aerobatics of dogfighting. Because a pilot's only warning system was the naked eye, attacking fighters, whenever possible, approached from the rear or dove out of the sun, where they could not be seen. The German ace Max Immelmann, in exploiting the superior abilities of his Fokker Eindeker to climb and dive quickly, helped expand aerial combat from the horizontal into the vertical dimension. Immelmann developed what became known as the Immelmann turn, in which an attacking fighter dove past the enemy craft, pulled sharply up into a vertical climb until it was above the target again, then turned hard to the side and down so that it could dive a second time.

Fighters operated at least in pairs, flying 50 to 60 yards apart, so that the wingman could protect the leader's rear. Flying speed averaged 100 miles per hour, and communication was by hand signaling, rocking the wings, and firing coloured flares.

The next role to emerge for military aircraft was ground attack, in which planes, by strafing with machine guns and dropping rudimentary bombs, aided an advance on the ground, helped cover a retreat, or simply harrassed the enemy. By the late stages of the war, ground-attack aircraft had forced almost all large-scale troop movements to be carried out at night or in bad weather.

By war's end a fourth vision of air power arose—that of an independent air force attacking the enemy far from the front lines, the purpose being to destroy essential elements of the enemy's war capability by bombing factories, transportation and supply networks, and even centres of government. This role, never effectively implemented in World War I, was spurred largely by the German air attacks on London. Carried out at first by zeppelin airships, the bombing was later done by aircraft such as the Gotha bomber, which, by flying at night and often as high as 20,000 feet (forcing the crew to breathe bottled oxygen through a tube in the mouth), operated beyond the ceiling of many defensive fighters.

Thus, the basic roles that aircraft would play in modern war were presaged in World War I: reconnaissance, air superiority, tactical ground support, and strategic bombing.

THROUGH WORLD WAR II

The all-metal monoplane represented a huge increase in performance and firepower over the aircraft of World War I, and the effects were first seen in fighter tactics.

Air superiority. Airspeeds of the new fighters jumped to more than 400 miles per hour, and some planes could operate at altitudes of 30,000 feet. Wing-mounted machine guns and aerial cannon were lethal at 600 yards, and pilots communicated with one another and the ground via the radio telephone. These developments—especially the The greater speeds—led Germans participating in the Span-fighting ish Civil War (1936–39) to fly their Me-109 fighters in pair and loose, line-abreast *Rotten,* or pairs, about 200 yards apart. the finger- Two of these *Rotten* formed a *Schwarm,* and this flexible four formation—called "finger-four" by English-speaking airmen—was eventually adopted by all the major air forces in World War II.

Attacking out of the sun was still favoured, both because it preserved the element of surprise and because diving added speed. An alert defending fighter pilot, however, might use his attacker's speed to his own advantage by executing a scissors maneuver, in which he would turn sharply one way and then the other, reducing his forward motion so that the speeding attacker would overshoot and find the intended victim on his tail. Tight maneuvers such as the scissors were most effective when attempted with such agile fighters as the British Spitfire and the Japanese "Zero." Fighters such as the Me-109 and the U.S. P-47 Thunderbolt, which were noted for their speed, best escaped by diving hard and pulling back up when the attacker had been shaken.

A diving maneuver called the split-S, half-roll, or *Abschwung* was frequently executed against bombers. Heavily armed fighters such as the British Hurricane or the German Fw-190, instead of approaching from the side or from below and to the rear, would attack head-on, firing until the last moment and then rolling just under the big planes and breaking hard toward the ground. The object was to break up the bomber formations so that individual ships could be set upon and destroyed.

Defensive fighter squadrons were directed by radar control stations on the ground to the vicinity of the bombers, at which point the pilots would rely once more upon the naked eye. This was adequate for day fighting, when enemy bombers could be seen miles away, but at night the pilots had to get within a few hundred yards before spotting a bomber's silhouette against the sky or against the conflagration on the ground. For this reason, night fighting was ineffective until radar was installed in the planes themselves. This beginning of the age of electronic warfare

required a novel teamwork between pilot and navigator, and it was best carried out in two-seat aircraft such as the British Beaufighter and Mosquito and the German Ju-88 and Me-110. Some of these long-range, twin-engined night fighters also served as "intruders," slipping into enemy bomber formations, following them home, and shooting them down over their own airfields.

Ground attack. The German Air Force, or Luftwaffe, was configured primarily to fly in support of ground forces, and, in the Spanish Civil War and the first years of World War II, the Ju-87 Stuka dive-bomber was its prin- Dive-cipal ground-attack craft. In a typical Stuka attack, several bombing planes would circle above the target, then one plane after another would peel off to dive almost vertically before releasing its bombs, pulling up, and returning to the circle to dive again. In the Pacific Theatre, carrier-based dive-bombers such as the U.S. Dauntless and Helldiver and the Japanese Type 99 "Val" applied this maneuver to naval warfare. Dropping straight down from a cruising altitude of about 15,000 feet and releasing their bombs from below 2,000 feet, these planes destroyed or damaged many battleships and aircraft carriers. During the assault phase of amphibious landings, U.S. dive-bombers helped compensate for the flat trajectories of naval guns in disabling Japanese shore defenses. Because dive-bombers generally had top speeds in level flight of less than 300 miles per hour, they were most effective where air superiority had been secured by fighters such as the Zero or the U.S. F6F Hellcat. Spitfire pilots of the RAF made such short work of unescorted Stukas that they referred to these one-sided dogfights as "Stuka parties."

Ground attack was most devastating when conducted by fighter-bombers, which were often converted air-superiority fighters. Taking advantage of their speed, British Spitfires and Mosquitos and U.S. P-51 Mustangs and P-38 Lightnings, flying very low to avoid radar detection, bombed and strafed countless airfields and infantry columns. Pilots of the P-51, after escorting bombers into Germany (see below), often freely attacked ground targets while racing back to England at treetop level. In North Africa in 1942–43, the Royal Air Force (RAF) perfected close-air support by concentrating its air power under a centralized control that was exercised jointly by the senior ground and air commanders in the theatre of operations. This system, by concentrating maximum force at decisive points as the desert campaigns unfolded, achieved a flexibility of employment that later emerged as the central tenet of air power.

Strategic bombing. World War II saw massive bombing of military targets and major cities. The big, slow-moving bombers operated in formations (sometimes numbering 1,000 or more) that were intended not to evade enemy defenses but to beat them back or simply swamp them with numbers.

The key to bombing during the day was to provide an escort of fighters adequate to turn back defending fighters. (Antiaircraft artillery was of little hazard to bombers flying above 20,000 feet.) During the Battle of Britain (1940–41), a typical formation of German He-111 and Do-217 bombers would cross the English Channel at about 15,000 feet. Close escort would be provided by Fw-190s weaving in and out of the formation, while high and top cover would be provided by Me-109s stacked behind the bombers up to about 25,000 feet. The added height would enable the Me-109s to jump the RAF's Spitfires and Hurricanes while they were still climbing. Even more effective were fighter sweeps, in which Me-109s would leave the bombers and attack distant airfields before the defending fighters could get off the ground. But the Luftwaffe, in one of the major miscalculations of the aerial war, usually confined its fast, deadly fighters to a closer escort of the bomber formations.

The U.S. Army Air Force learned the value of fighter sweeps in its long-range daylight bombing of Germany, but not before placing an unfounded faith in the capacity of its B-17 Flying Fortress and B-24 Liberator bombers to defend themselves with their own heavy armament. In The defen-late 1942 and early 1943 these bombers began to fly in sive box what became known as the "combat box" formation, de- formation

vised by Colonel (later General) Curtis E. LeMay. In such a formation, a single combat wing of about 48 bombers would be divided into three groups, with the lead group flying at 20,000 feet and the others trailing in echelon at intervals of 500 to 1,000 yards and at slightly higher altitudes. Within each group would be three squadrons, composed of two elements of three aircraft each, and the bombers would be staggered in such a way as to give their guns as free a field of fire as possible to cover themselves and their fellows.

The defensive formation was sorely tested in 1943, when, flying beyond the radius of the fighter escorts then available (less than 200 miles), U.S. bombers suffered losses too severe to be borne regularly. Activity over Germany was curtailed until the arrival in force the next year of P-51s equipped with droppable external fuel tanks that enabled the fighters to fly escort the 1,000 miles to Berlin. With enough fighters to allow one escort for every bomber, some P-51s were cut loose to sweep the airspace hundreds of miles away. In this way, the Luftwaffe was finally overwhelmed.

Night bombing relieved bombers of the fighter threat (at least until effective radar was installed in planes), but it presented difficulties in finding and hitting targets. With visual navigation impossible except on the clearest moonlit nights, electronic aids became vital. In the blitz of London and other cities, the Luftwaffe used a system called *Knickebein*, in which bombers followed one radio beam broadcast from ground stations on the continent until that beam was intersected by another beam at a point over the target. Lead bombers dropped incendiary bombs, which set fires that guided other bombers carrying high explosives as well as more incendiaries.

The RAF used two radar-beam systems called Gee and Oboe to guide its Lancaster and Halifax bombers to cities on the Continent. In addition, the bombers carried a radar mapping device, code-named H_2S, that displayed reasonably detailed pictures of coastal cities such as Hamburg, where a clear contrast between land and water allowed navigators to find the target areas. In order to "spoof" the Germans' radar warning system, RAF planes dispensed "window," which consisted of clouds of tinfoil strips that masked the bombers' movements.

Because Japan had no radar, U.S. B-29 Superfortresses did not face dangerous opposition in their long-range assaults on the Japanese home islands beginning in November 1944. Nevertheless, unpredictable weather over the target areas, plus the action of the jet stream on bombs dropped from 30,000 feet, made high-altitude bombing imprecise. In response, LeMay ordered low-level bombing runs. Flying at night to avoid enemy defenses, B-29s dropping incendiary bombs from 5,000 to 9,000 feet devastated more than 60 cities between March and July 1945.

THE JET AGE

Toward the end of World War II, the first operational jet fighter, the German Me-262, outflew the best Allied escorts while attacking bomber formations. This introduced the jet age, in which aircraft soon flew at more than twice the speed of sound (741 miles per hour at sea level and 659 miles per hour at 36,000 feet) and easily climbed to altitudes of 50,000 feet. At the same time, advanced electronics removed the task of early warning from the pilot's eye, and guided missiles extended the range of aerial combat, at least in theory, to beyond visual range.

Air superiority. Flying at supersonic or near-supersonic speeds, often climbing into the thin air of the stratosphere, jet fighters were far less maneuverable than their propeller-driven predecessors. This made necessary a formation even more flexible than the finger-four. One solution was the fluid-four, in which two fighters flying 300 yards apart would be trailed by another pair flying 2,000 to 3,000 yards to the side, 600 yards back, and 1,000 yards above. Separation of a mile or more would allow the trailing pair to cover the lead pair from surprise attack. The basic fighting element remained the pair, often favouring a "loose deuce" formula in which either pilot, depending upon the combat situation, could adopt the role of lead fighter while the other covered as wingman.

Because jet fighters had excellent climbing but poor turning ability, fighting in the vertical plane became more important than ever. The scissors maneuver acquired a vertical variation, in which two fighters would execute a series of climbing turns or barrel rolls, each with the aim of slipping behind the plane that climbed too fast. Speed—usually the greatest asset of the fighter—could easily become a liability, and many maneuvers were developed to preserve its advantage. One such maneuver was the "high-speed yo-yo," in which an attacking fighter, in pursuing a more maneuverable opponent in a tight circle, would pull up while turning; this would reduce his speed, allowing him to remain within the circle while placing him in a position to swoop down from above.

Supersonic speed actually accounted for a tiny fraction of flying time, since igniting the jet's afterburner could consume a fighter's fuel in minutes. Military cruising speed was almost always subsonic, with the afterburner being used only for pursuit or escape. In fact, fuel became such a pressing concern in jet warfare that fighters often could spend no more time flying combat air patrol than they spent flying to and from the patrol area.

Suppression of air defense. Beginning in the 1960s, radar-directed antiaircraft weapons proved so dangerous that they threatened to sweep aircraft from the sky. By flying low and fast, jinking (making quick, irregular changes in direction and speed), or diving in a steep spiral, aircraft often succeeded in evading these weapons, but only at the price of spoiling the mission. Air defenses had to be destroyed; in order to do this, aircraft had not only to outfly and outgun the weapons but also to foil their guidance mechanisms with electronic countermeasures (ECM).

In the Vietnam War the North Vietnamese deployed a formidable air-defense system based on Soviet-made antiaircraft guns and SA-2 surface-to-air missiles (SAMs). In response, the U.S. Navy and Air Force mounted complex air strikes employing aircraft of multiple types and capabilities. One such operation might begin with F-4 Phantom II fighter-bombers entering the target area first to drop clouds of radar-reflecting metallic fibres called chaff. These would be followed by F-105 Thunderchiefs modified into "Wild Weasels" by the addition of radar homing and warning devices designed to jam some enemy radars and locate others. The Wild Weasels would guide other F-105s armed with radar-homing missiles, which would destroy the radars and SAM sites and clear the target area for the main strike force.

That air warfare in the jet age had effectively become electronic warfare was confirmed by the Arab-Israeli War of October 1973. In the first two days of that conflict, Israel lost 40 aircraft to Egyptian and Syrian air defenses. In June 1982, however, the Israeli air force displayed a new mastery of tactics in the electronic age by destroying Syrian SAM sites in al-Biqāʿ Valley, Lebanon. The attack began with a wide array of ECM equipment—Boeing 707s modified into electronic warfare aircraft, E-2C Hawkeye early warning aircraft, and A-4 Skyhawks flying reconnaissance—to confuse and deceive Syrian communications and the radars of Syrian SA-2, SA-3, SA-6, and SA-8 SAM units. Small remotely piloted vehicles were sent over the valley; when the Syrians fired on these, Israeli F-4s spotted the SAM sites and destroyed them with radar-homing missiles and cluster bombs. Israeli F-15 Eagles and F-16 Fighting Falcons then destroyed the Syrian air force, downing more than 80 MiG-21s and MiG-23s.

Strategic bombing. The importance of ECM in long-range bombing became apparent in 1972, when U.S. B-52 Stratofortresses struck targets in North Vietnam. By flying under escort at night and at about 30,000 feet, the B-52s were reasonably safe from MiG fighters and antiaircraft guns, and Wild Weasel and chaff-dropping aircraft helped suppress the SA-2s. But the most important ECM was provided by jammers built into the bombers. These flew in cells of three in order to create "blankets" of radar suppression that largely foiled the SAMs.

The next generation of variable-wing bombers, such as the U.S. B-1 and the Soviet Tu-26 Backfire, were designed to avoid more sensitive electronic warning systems by penetrating enemy airspaces at extremely low altitude.

Electronic countermeasures

The fluid-four and loose deuce

Flying in groups was to be abandoned, since the large radar cross section and radio communication of several bombers would be easily detected. Instead, the new bombers were designed for solo missions and carried standoff weapons such as nuclear-armed cruise missiles, which could be launched beyond the range of SAMs guarding the target areas. (D.MacI.)

Logistics

FUNDAMENTALS

In the conduct of war, war-making activity behind the cutting edge of combat has always defied simple definition. The military vocabulary offers only a few general descriptive terms (such as administration, services, and the French *intendance*), all corrupted by loose usage and none covering the entire area of noncombat activity. All carry additional, though related, meanings that make them ambiguous.

Logistics belongs to this group. Its archaic meaning, the science of computation (from the Greek *logistikos,* "skilled in calculating"), persists in mathematics as the logistic or logarithmic curve but seems unrelated to modern military applications. In the 18th century it crept into French military usage with a variety of meanings, including "strategy" and "philosophy of war." But the first systematic effort to define the word with some precision and to relate it to other elements of war was made by Antoine-Henri Jomini (1779–1869), the noted French military thinker and writer. In his *Summary of the Art of War* (1838), Jomini defined logistics as "the practical art of moving armies," by which he evidently meant the whole range of functions involved in moving and sustaining military forces—planning, administration, supply, billeting and encampments, bridge and road building, even reconnaissance and intelligence insofar as they were related to maneuver off the battlefield. In any case, Jomini was less concerned with the precise boundaries of logistics than with the staff function of coordinating these activities. The word, he said, was derived from the title of the *major général* (or *maréchal) des logis* in French 18th-century armies, who, like his Prussian counterpart, the *Quartiermeister,* had originally been responsible for the administrative arrangements for marches, encampments, and troop quarters (*logis*). These functionaries became the equivalent of chiefs of staff to the commanders of the day.

Jomini's discussion of logistics was really an analysis of the functions of the Napoleonic general staff, which he conceived as the commander's right arm, facilitating his decisions and seeing to their execution. The mobility and gargantuan scale of Napoleonic warfare had left the simple old logistics of marches and encampments far behind. The new logistics, said Jomini, had become the science of generals as well as of general staffs, comprising all functions involved in "the execution of the combinations of strategy and tactics."

This broad conception had some validity in Jomini's day. He left an engaging picture of Napoleon, his own logistician, sprawled on the floor of his tent, marking each division's route of march on the map with a pair of dividers. But as staff organization and activity became more complex, along with war itself, the term logistics soon lost its association with staff activity and almost disappeared from the military vocabulary. Jomini's great contemporary, the Prussian theorist Carl von Clausewitz, did not share his conception of logistics, which he called "subservient services" that were not part of the conduct of war. Jomini's own influence, which was enormous in his day, was mainly on strategic and tactical thought, particularly in the American Civil War.

In the late 1880s the American naval historian Alfred Thayer Mahan introduced logistics into U.S. naval usage and gave it an important role in his theory of sea power. In the decade or so before World War I the navy's concern with the economic foundations of its expansion began to broaden the conception of logistics to encompass industrial mobilization and the war economy. Reflecting this trend, a U.S. marine officer, Lieutenant Colonel Cyrus Thorpe, published his *Pure Logistics* in 1917, arguing that

the logical function of logistics, as the third member of the strategy–tactics–logistics trinity, was to provide all the means, human and material, for the conduct of war, including not merely the traditional functions of supply and transportation but also war finance, ship construction, munitions manufacture, and other aspects of war economics.

Providing all the means for the conduct of war

After World War II the most notable effort to produce a theory of logistics was by a retired rear admiral, Henry E. Eccles, whose *Logistics in the National Defense* appeared in 1959. Expanding Thorpe's trinity to five (strategy, tactics, logistics, intelligence, communications), Eccles developed a conceptual framework that envisaged logistics as the military element in the nation's economy and the economic element in its military operations—that is, as a continuous bridge or chain of interdependent activities linking combat forces with their roots in the national economy. Eccles stressed the tendency of logistic costs to rise (the logistic "snowball") and, echoing Jomini, the essential role of command. Despite its logic and symmetry, however, Eccles' overarching conception of logistics was not widely accepted. Official definitions still vary widely, and most ordinary dictionaries adhere to the traditional "supply, movement, and quartering of troops," but neither has much influence on common usage, which remains stubbornly inconsistent and loose.

Components of logistics. It is useful to distinguish four basic elements or functions of logistics: supply, transportation, facilities, and services. (A fifth, management or administration, is common to all organized human activity.) All involve the provision of needed commodities or assistance to enable armed forces to live, move, communicate, and fight.

Supply. Supply is the function of providing the material needs of military forces. The supply process embraces all stages in the provision and servicing of military material, including those preceding its acquisition by the military—design and development, manufacture, purchase and procurement, storage, distribution, maintenance, repair, salvage, and disposal. (Transportation is, of course, an essential link in this chain.) The whole process can be divided into four phases: (1) the design–development–production process of creating a finished item, (2) the administrative process by which military agencies acquire finished items, (3) the distribution–servicing processes undergone by military material while "in the service," and (4) the planning–administrative process of balancing supply and demand—that is, the determination of requirements and assets and the planning of production, procurement, and distribution.

Military supply has always had the basic aim of providing military forces the material needed to live (food, water, clothing, shelter, medical supplies), to move (vehicles and transport animals, fuel and forage), to communicate (the whole range of communications equipment), and to fight (weapons, defensive armament and materials, and the expendables of missile power and firepower). In all these categories are items, such as clothing, vehicles, and weapons, that are used repeatedly and therefore need to be replaced only when lost, destroyed, or worn out; and materials, such as food, fuel, and ammunition, that are expended or consumed—that is, used only once—and therefore must be continuously or periodically resupplied. From these characteristics are derived the basic classifications of initial issue, replacement, and resupply. The technical classifications of supply vary among countries and services. The British army, for example, recognizes two broad classes: (1) supplies, which include all the expendables except ammunition, and (2) stores, which include ammunition and military hardware. The U.S. Army in World War II and for many years after used five main classifications: (1) subsistence and forage, (2) equipment and other items regularly issued to organizations and individuals, (3) fuels, (4) equipment and materials of irregular issue such as construction materials, and (5) ammunition. These five classes were subsequently expanded to 10 by designating as separate classes certain large categories, such as vehicles, medical material, repair parts, and sales items, which formerly were considered as subclasses.

Historically, food and forage made up most of the bulk

"The practical art of moving armies"

The two principal components of supply: food and fuel

and weight of supply until the 20th century, when, with mechanization and air power, fuel displaced forage and became the principal component of supply. However, the demand for food remains unremitting and undeferrable, the one constant of logistics. A man's daily ration makes a small package—seven pounds and often much less. But an army of 50,000 may consume in one month as much as 4,500 tons (4.1 million kilograms) of food.

Animals require much more. The standard grain and hay ration in the 19th century was about 25 pounds (11.4 kilograms), and the daily forage of a corps of 10,000 cavalry weighed as much (allowing for remounts) as the food for 60,000 men. Forage requirements tended, moreover, to be self-generating, since the animals needed to transport it also had to be fed. The number of animals accompanying an army varied widely. Napoleon's ideal, which he himself never attained, was a supply train of only 500 wagons in an army of 40,000; with a corps of 7,000 cavalry, this would amount to about 10,000 animals exclusive of remounts and spare draft animals. Northern armies in the American Civil War commonly numbered half as many animals as soldiers. A force of 50,000 men might thus require more than 300 tons (272,000 kilograms) of forage daily. This was more than twice the weight of gasoline that an equivalent force of three World War II infantry divisions, using motor vehicles exclusively, needed to operate for the same length of time. In the latter case, moreover, fuel requirements diminished markedly when an army was not moving, whereas the premechanized force had to feed its animals whether moving or not. It was the immense forage requirements of premechanized armies, more than any other single factor, that restricted warfare before the 20th century so generally to seasons and climates when animals and men could subsist mainly on the countryside.

In 20th-century warfare the expendables of movement include fuel for rail and water transport as well as for motor vehicles, and also the immense fuel requirements of modern air power. In World War II, without counting transoceanic shipment, fuel made up half the resupply and replacement needs of U.S. forces in Europe. Technologically advanced warfare has, in fact, vastly increased fuel consumption both absolutely and relatively to other supply needs. The continued development of mechanization and air power has increased by one and one-half times the fuel requirements of large-scale conventional military operations typical of World War II. Food, by contrast, is a small and diminishing fraction of the total burden.

Before the 20th century, equipment replacement and ammunition resupply were a relatively small part of an army's needs. Missile power before the gunpowder era was limited by the difficulty of bringing missiles in quantity to the battlefield. For the first five centuries of the gunpowder era the provision of ammunition was not a major logistic problem. Not until the use of field artillery on a large scale in the late 18th century, and the development of quick-firing shoulder arms in the 19th, did ammunition begin to constitute a substantial part of resupply needs. As late as 1864, in the Atlanta campaign of the American Civil War, the Union army's average daily ammunition requirements amounted to only one pound (0.45 kilogram) per man, as against three pounds for rations; Confederate forces in that war were reported to expend, on the average, only half a cartridge per man per day.

Supplying ammunition

The great increase in firepower in the 20th century upset the historic ratios. In World War II the average ammunition requirements of Western forces in combat zones were 12 percent of total needs. In the mainly positional Korean War, ammunition expenditures climbed higher, and a late-1980s U.S. Army planning factor rated ammunition requirements as more than one-quarter of total supply. Material replacement needs have also mounted in absolute terms; the great tank battles of World War II and of the Arab-Israeli Wars of 1967 and 1973 involved the destruction of hundreds of tanks within a few days. But as a percentage of total supply, replacement of material losses is a declining factor.

Transportation. Before the development of steam propulsion, armies depended for mobility on the muscles of men and animals and the force of the wind. On land

they used men and animals to haul and carry; on water they used oar-driven and sail-propelled vessels. Among these various modes the balance of advantage was often delicate. A force moving by water was vulnerable to storm and enemy attack; navigation was an uncertain art; transports were expensive and of limited capacity. Large expeditions could be undertaken only by wealthy states or seafaring peoples, such as the Scandinavians of the 8th and 9th centuries, who combined the roles of mariner and warrior. Seaborne armies were rarely strong enough to overcome a resolute land-based foe.

On the other hand, armies have usually been able to move faster and with a better chance of avoiding enemy detection by water than by land. Shipment of bulky freight is cheaper and safer by river than by road, and good roads are rare in military history. In the 19th and 20th centuries the revolution in ship design and propulsion made water travel largely independent of wind and weather, permitting the overseas movement and support of larger forces than ever before. After the mid-19th century, however, more and better roads and, above all, railroads began to offset the historic advantages of water transportation to some degree. In the 20th century motor vehicles and more road building extended the conquest of rough terrain. The airplane finally freed military movement, for modest forces and limited cargo, from bondage to earth altogether. Yet the costs of mobility on land—in equipment, materials, and energy—remain high, and large military movements are still confined to narrow ribbons of rail and road, which in many parts of the world are still rare or lacking.

The advantages of sea and air transport

On land the soldier himself has been the basic burden carrier of armies. As a matter of simple economy, he represents large carrying capacity at no extra cost. His equivalent, in an army of 50,000 in the preindustrial era, would be 1,875 wagons drawn by 11,250 horses or mules, which might need additional wagons and animals to haul forage. A difference of only five pounds (2.3 kilograms) in the soldier's load could add or subtract a requirement for 125 wagons and 750 animals. Since the days of the Roman legion, the soldier has had to carry, on the average, about 55 or 60 pounds (25 or 27 kilograms). The ratio between weapons and other items in the soldier's load has varied widely, but the modern soldier has relegated most of his food to vehicle transport while still carrying a heavy burden of weapons and ammunition. Since World War II, however, some armies have made drastic reductions in the combat load.

Before the age of mechanization, the soldier's carrying capacity was usually supplemented by additional carriers and haulers, human and animal. Each had advantages. A team of six horses ate about as much as 30 to 40 men, but the men could carry more on their backs than the horses could haul and considerably more than the horses could carry. Men could negotiate rougher terrain, and they required less care. On the other hand, loads placed on men had to be distributed in small packages, and men proved less efficient than animals when teamed to haul heavy and bulky loads. The horse and mule, however, have less strength and stamina, though more agility, than the ox, history's primary beast of burden. In many parts of the world, motor transport still has not displaced human and animal carriers and haulers in the movement of military supply.

Human and animal haulers

Facilities. The provision of military facilities, as distinct from fortification, did not become a large and complex sphere of logistic activity until the transformation of warfare in the industrial era. In that transformation the traditional function of providing nightly lodgings or winter quarters for the troops dwindled to relative insignificance in the mushrooming infrastructure of fixed and temporary installations that became part of the military establishments of the major powers. Modern armies, navies, and air forces own and operate factories, arsenals, laboratories, power plants, railroads, shipyards, airports, warehouses, supermarkets, office buildings, hotels, hospitals, homes for the aged, schools, colleges, and many other types of structures used by advanced societies in the 20th century—as well as barracks, the original military facility. They are among the world's great landowners. The management of

all this improved real estate is one of the largest areas of modern logistic administration.

Services. Services may be defined as activities designed to enable personnel or material to perform more effectively. Usage recognizes no clear distinction between logistic and nonlogistic services, but a somewhat blurred one has grown out of the traditional and opprobrious identification of logistics with noncombat rear-area activities. Thus, intelligence and communications personnel and combat engineers in the U.S. Army have long claimed the label of "combat support" as distinct from the "service support" functions of supply, transportation, hospitalization and evacuation, military justice and discipline, custody of prisoners of war, civil affairs, personnel administration, and nontactical construction (performed by "construction" engineers). Training of combat troops is hardly ever considered a logistic service, whereas training of service troops sometimes is. Usage does not, however, always assign "service support" to logistics. Personnel administration is an old, institutionalized sector of the military establishment, and personnel administrators tend to reject the logistics label. Personnel services (medical, spiritual, educational, financial) are more heterogeneous and have varied origins; most definitions of logistics include them.

Most service activities, logistic and nonlogistic, are of recent origin and, as organized specialities, are peculiar to the military establishments of advanced nations. Over the long haul of military history, the services considered necessary to keep armed forces in fighting trim were generally of a rudimentary character. From the earliest times, however, they posed a serious logistic problem. To armies and their lines of communication they added numbers of people who did not, as a primary function, belong to the fighting force and who, if not properly organized, might weaken its capacity to fight. Soldiers seldom possessed the technical skills required to perform any but the simplest services; sometimes, as members of a warrior elite, they were prohibited by social prerogative from performing them. A classic feature of armies, consequently, has been its long train of noncombatants, often far outnumbering the fighting men.

Logistic services also added to the baggage of armies a growing burden of specialized equipment, tools, and materials needed for the performance of the services. Services tended to generate more services: service equipment itself had to be serviced, sometimes by additional technicians, and service personnel themselves required services. Logistic services thus meant more people to be fed, clothed, and sheltered and more people and baggage to be transported. What the British call the "administrative tail" is as old as military history.

Special features of naval logistics. From early times, the substantial carrying capacity of the warship made it an indispensable element in its own logistic support, particularly in the era before steam power eliminated the problem of covering long distances between ports. (Oar-driven warships, such as the Greek trireme, sacrificed this feature in order to maximize fighting power.) For centuries the most critical item of supply was water, which sailing ships found difficult to carry in sufficient quantities and to keep potable for long voyages. Food was somewhat less of a problem, except for its notoriously poor quality in the days before refrigeration, the sealed container, and sterilization.

During the long reign of the sailing ship, the absence of a fuel requirement was a major factor in the superior mobility of fleets over armies. The shift to steam was, in a sense, a return to the principle of self-contained propulsion earlier embodied in the oar-driven ship. The gain in control was of course an immeasurable improvement for the long haul, but for a time the inordinate amount of space that had to be allocated to carry wood or coal seriously inhibited the usefulness of early warships. Eventually the maritime nations established networks of coaling stations, which became part of the fabric of empire in the late 19th century. The shift to oil a few years before World War I involved a major dislocation in naval logistics and changed the stakes of imperial competition.

For modern navies the importance of bases goes far beyond the need for periodic replenishment of fuel, although this remains essential. Ships must be repaired, overhauled, and resupplied with ammunition and food; and, an ancient requirement, the crews must be given shore leave. Within limits, these needs can be filled by specialized auxiliary ships either accompanying naval forces at sea or stationed at predetermined rendezvous points. Naval operations in World War II saw a proliferation of these auxiliary vessels; in 1945 only 29 percent of the U.S. Navy consisted of purely fighting ships. By using auxiliaries and by rotating ships and personnel, modern fleets can remain at sea indefinitely, especially if not engaged in combat. U.S. fleets in the Mediterranean and far Pacific have done so for years, although the feat is less impressive than that of the British admiral Lord Nelson's fleet, which lay off Toulon, Fr., continuously, without rotation, for 18 months from 1803 to 1805. With nuclear propulsion, thus far applied only to submarines and a handful of large warships, the basic logistic function of replenishing fuel may eventually disappear. But that day will be long in coming, and the other functions of naval logistics will remain.

Power versus movement. The potential effectiveness of a military force derives from three attributes: fighting power, mobility, and range of movement. Which of these attributes is stressed depends on the commander's objectives and strategy, but all must compete for available logistic support. Three methods have been used, in combination, in providing this support for forces in the field: self-containment, local supply, and supply from bases.

Self-containment. The idea of complete independence from external sources of supply—the hard-hitting, self-contained "flying column"—has always been alluring but has seldom fully materialized. Self-containment in weapons, equipment, and missiles or ammunition was common enough before the great expansion of firepower and resupply requirements in the last century. But few military forces have been able to operate for long or move far without frequent resupply of food and forage or fuel.

Self-containment is the least economical of all methods of supply. Accompanying transport is fully employed only at the beginning of the movement, serving thereafter as a rolling warehouse that is progressively depleted as the force moves. Fast-moving, self-contained forces typically left a trail of abandoned vehicles and dead animals. The basic trade-off in self-containment is between the speed gained by avoiding delays and detours for foraging and the speed lost by dragging a large baggage train. When Hannibal crossed the Alps into northern Italy in 218 BC, he bypassed the Roman army guarding the easier coastal route; but his movement through the mountain passes was painfully slow, and he lost almost half his force to cold, disease, and hostile tribes along the way.

Local supply. Until the 20th century, armies commonly lived off the country and, in enemy territory, from captured stores. In fertile regions an army could usually provision itself at low cost in transport and without sacrificing fighting power or range; when efficiently organized, local supply even permitted a high degree of mobility. Normally, however, an army living off the country tended to straggle and to load itself down with loot. If it moved too slowly or was pinned down, it might sweep the region bare and starve. In winter, in deserts and mountains, or in thinly populated areas, local supply offered meagre fare. And a hostile population, as Napoleon discovered in Russia and Spain, could bring disaster to an army that had to scrounge for its food. (British forces in the American colonies during the Revolution had to draw most of their supplies from overseas.) Animals, in any case, almost always had to shift for themselves. Cattle driven with an army could transform forage into food, a supply technique as ancient as the Bible and still common in the 19th century. Unwieldy and slow-moving though it was, the accompanying herd had the great merit of transporting itself and dwindling as it was consumed.

When mechanized transport replaced animals, one of the great continuities of military history was broken. Mechanized armies can operate in winter and desert areas as long as they have fuel; when that runs out, they grind to a

halt. Until fuel can be compressed into small capsules (as, in a sense, atomic energy is) or, like forage, be gathered along the way, the door to both self-containment and local supply will remain closed.

Supply from bases. The alternative to self-containment and local supply is continuous or periodic resupply and replacement from stores prestocked at bases or other accessible points. Supply from bases involves three serious disadvantages. First, supply routes are often vulnerable to attack. Second, an army shackled to its bases lacks flexibility and moves slowly—even more slowly as it advances. Finally, the transportation costs of maintaining a flow of supply over substantial distances are heavy and, beyond a point, prohibitive. The reason is twofold; first, because the transport of the supply train must operate a continuous shuttle—that is, for each day's travel time, two vehicles are needed to deliver a single load—and, second, because additional food and forage or fuel must be provided for the personnel, animals, or vehicles of the train itself. In the era of animal-drawn transport this multiplier factor set practical limits to the operating radius of an army, which the American Civil War general William T. Sherman fixed at about 100 miles (160 kilometres), or five days' march, from its base. The critical limitation was the provision of forage, the bulkiest supply item. For an army operating at any considerable distance from its bases, the in-transit forage requirements of its shuttling supply train, if supplied entirely from bases, would saturate any amount of transport, leaving none to supply the fighting force. Since premechanized armies usually found some local forage and food, supply from bases, in combination with local supply and an accompanying train, was the normal method, but Sherman's 100 miles was seldom exceeded.

With modern mechanized transport the theoretical maximum operating radius is so great that other limitations come into play. Nevertheless, the in-transit fuel needed to supply a force from distant bases adds major increments of transport cost, especially under conditions (*e.g.,* poor roads) that reduce speed or increase fuel consumption. It can also severely limit the speed of an advancing mechanized force, as shown by the bogdown of the U.S. 3rd Army's drive across France in the summer of 1944 for lack of fuel.

HISTORICAL DEVELOPMENT

Logistic systems before 1850. In ancient history the combination of local supply for food and forage and self-containment in hardware and services appears often as the logistic basis for operations by forces of moderate size. Some of these operations are familiar to many a schoolchild—the long campaign of Alexander the Great from Macedonia to the Indus, the saga of Xenophon's Ten Thousand, Hannibal's campaigns in Italy. The larger armies of ancient times—like the Persian invaders of Greece in 480 BC—seem to have been supplied by depots and magazines along the route of march. The Roman legion combined all three methods of supply in a marvelously flexible system. The legion's ability to march fast and far owed much to superb roads and an efficiently organized supply train, which included mobile repair shops and a service corps of engineers, artificers, armourers, and other technicians. Supplies were requisitioned from local authorities and stored in fortified depots; labour and animals were drafted as required. When necessary, the legion could carry in its train and on the backs of its soldiers up to 30 days' supply of provisions. In the First Punic War against Carthage (264–241 BC), a Roman army marched an average of 16 miles (26 kilometres) a day for four weeks.

One of the most efficient logistic systems ever known was that of the Mongol cavalry armies of the 13th century. Its basis was austerity, discipline, careful planning, and organization. In normal movements the Mongol armies divided into several corps and spread widely over the country, accompanied by trains of baggage carts, pack animals, and herds of cattle. Routes and campsites were selected for accessibility to good grazing and food crops; food and forage were stored in advance along the routes of march. On entering enemy country, the army abandoned its bag-

gage and herds, divided into widely separated columns, and converged upon the unprepared foe at great speed from several directions. In one such approach march a Mongol army covered 180 miles (290 kilometres) in three days. Commissariat, remount, and transport services were carefully organized. The tough and seasoned Mongol warrior could subsist almost indefinitely on dried meat and curds, supplemented by occasional game; when in straits, he might drain a little blood from a vein in his mount's neck. Every man had a string of ponies; baggage was held to a minimum, and equipment was standardized and light.

In the early 17th century, King Gustav II Adolf of Sweden and Prince Maurice of Nassau, the military hero of the Netherlands, briefly restored to European warfare a measure of mobility not seen since the days of the Roman legion. This period saw a marked increase in the size of armies; Gustav and his adversaries mustered forces as large as 100,000, Louis XIV of France late in the century even more. Armies of this size had to keep on the move to avoid starving; as long as they did so, in fertile country they could usually support themselves without bases, even with their customary huge noncombatant "tail." Logistic organization improved, and Gustav also reduced his artillery train and the size of guns. In the Thirty Years' War (1618–48) strategy tended to become an appendage of logistics as armies, wherever possible, moved and supplied themselves along rivers exploiting the economies of water transportation, and operated in rich food-producing regions.

After the Thirty Years' War, European warfare became more sluggish and formalized, with limited objectives and an elaborate logistics that sacrificed both range and mobility. The new science of fortification made towns almost impregnable while enhancing their strategic value, making 18th-century warfare more an affair of sieges than of battles. Two logistic innovations were notable: the magazine, a strategically located prestocked depot, usually established to support an army conducting a siege; and its smaller, mobile version, the rolling magazine, which carried a few days' supply for an army on the march. Secure lines of communication became vital, and whole armies were deployed to protect them. The increasing size of armies and of artillery and baggage trains placed heavier burdens on transport. Also, a revulsion against the depredations and inhumanity of the 17th-century religious wars resulted in curbs on looting and burning and in regulated requisitioning or purchase of provisions from local authorities. Because of the high cost of mercenary soldiery, commanders tended to avoid battles, and campaigns tended to become sluggish maneuvers aimed at threatening or defending bases and lines of communication. "The masterpiece of a successful general," Frederick the Great remarked, "is to starve his enemy."

The era of the French Revolution and the Napoleonic domination of Europe (1789–1815) brought back both mobility and range of movement to European warfare, along with an immense further increase in the size of armies. Abandoning the siege warfare of the 18th century, Napoleonic strategy stressed swift offensives aimed at smashing the enemy's main force in a few decisive battles. The logistic system inherited from the Old Regime proved surprisingly adaptable to the new scale and pace of operations. Organization was made more efficient, baggage trains were pared down and some of their load shifted to the soldier's back, and much of the noncombatant tail was eliminated. The artillery train was increased, and the rolling magazine was used as the occasion demanded. The heavily burdened citizen-soldier marched faster and farther than his mercenary predecessor. In densely populated and fertile regions, moving armies continued to subsist, by purchase and requisition, on the countryside through which they marched, spreading out over parallel roads, each corps foraging to one side only. Even so, the numbers involved dictated greater dependence on magazines.

Napoleon made relatively few logistic innovations. He militarized some services formerly performed by contractors and civilian personnel, but the supply service (*intendance*) remained civilian though under military control. A significant change was the establishment in 1807 of a fully

militarized train service to operate over part of the line of communication; this was divided into sections that were each serviced by a complement of shuttling wagons—foreshadowing the staged resupply system of the 20th century. The 600-mile advance of Napoleon's Grande Armée of 600,000 men into Russia in 1812 involved logistic preparations on an unprecedented scale. Despite extensive sabotage by the Russian peasantry, the system brought the army victorious to Moscow.

Logistics in the industrial era. *The revolution in warfare.* Between the mid-19th and the mid-20th centuries the conditions and methods of logistics were transformed by a fundamental change in the tools and modes of making war—perhaps the most fundamental change since the beginning of organized warfare. The revolution had four facets: (1) the mobilization of mass armies; (2) a revolution in weapons technology involving a phenomenal increase in firepower; (3) an economic revolution that provided the means to feed, arm, and transport mass armies; and (4) a revolution in the techniques of management and organization, which enabled nations to operate their military establishments more effectively than ever before.

These interrelated developments did not occur all at once. Armies of unprecedented size had appeared in the later years of the Napoleonic Wars. But for almost a century after 1815, the world saw no comparable mobilization of manpower except in the American Civil War. Meanwhile, the growth of population (in Europe, from 180 million in 1800 to 490 million in 1914) was creating a huge reservoir of manpower. By the end of the 19th century most nations were building large standing armies backed by even larger partially trained reserves. In the world wars of the 20th century the major powers mobilized armed forces numbering millions.

The revolution in weapons had started earlier but accelerated after about 1830. By the 1850s and '60s the rifled percussion musket, rifled and breech-loading artillery, large-calibre ordnance, and steam-propelled armoured warships were all coming into general use. The revolution proceeded with gathering momentum thereafter, but it remained for mass armies in the 20th century to realize its full potential for destruction.

By the mid-19th century the Industrial Revolution had already given Great Britain, France, and the United States the capacity to produce munitions, food, transport, and many other items in quantities no commissary or quartermaster have ever dreamed of. But except in the Northern states during the American Civil War, the wars of the 19th century hardly scratched the surface of the existing war-making potential. The nature of international rivalries of the period tended to limit war objectives and the mobilization of latent military power. Only in the crucible of World War I, at the cost of colossal blunders and wasted effort, did nations begin to learn the techniques of "total" war. Long before 1914, however, new instruments and techniques of logistics were emerging.

Transportation and communication. The railroad, the steamship, and the telegraph had a profound impact on logistic method during the last half of the 19th century. Beginning with the Crimean War (1854–56), telegraphic communication became an indispensable tool of command, intelligence, and operational coordination, particularly in controlling rail traffic. In the 20th century it yielded to more efficient forms of electronic communication—the telephone, radio, radar, television, telephotography, and the high-speed computer.

Railroads spread rapidly over western and central Europe and the eastern United States between 1850 and 1860. They were used—mainly for troop movements—in the suppression of central European revolutions in 1848–49, on a considerable scale in the Italian War of 1859, and extensively in the American Civil War, where they also demonstrated their capacity for long hauls of bulky freight in sustaining the forward movement of armies. In Europe, from 1859 on, railroads shaped the war plans of all the general staffs, the central features of which were the rapid mobilization and concentration of troops on a threatened frontier at the outbreak of war. In 1870, at the outset of the Franco-German War, the German states were able

to concentrate 550,000 troops, 150,000 horses, and 6,000 pieces of artillery on the French border in 21 days. Germany's recognized efficiency in mobilizing influenced the war plans of all the European powers in 1914. In both world wars Germany's railroads enabled it to shift troops rapidly between the Eastern and Western fronts.

Steam propulsion and iron ship construction also introduced new logistic capabilities into warfare in the 19th century. Steamships moved troops and supplies in support of U.S. forces in the Mexican War of 1846–48 and of British and French armies in the Crimea. River steamboats played an indispensable role in the American Civil War.

The complement of the railroad was the powered vehicle that could travel on ordinary roads and even unprepared surfaces, within the operating zones of armies forward of railheads. This was a 20th-century development, a combination of the internal-combustion engine, the pneumatic tire, and the endless track. Motor transport was used on an increasing scale in both world wars, although animal-drawn transport and railroads still dominated land movement. Another innovation was the pipeline, used to move water in the Palestine campaign of World War I and extensively in World War II to move oil and gasoline to storage points near the combat zones. More revolutionary was the development of large-scale air transportation. In World War II, units as large as a division were carried in one movement by air over and behind enemy lines and resupplied by the same means. Cargo aircraft maintained an airlift for more than three years from bases in India across the Himalayas into China; during the last eight months of operation it averaged more than 50,000 tons per month. But the fuel costs of such an operation were exorbitant. Air transportation remained primarily a means of emergency movement when speed was an overriding consideration.

The growth in quantity. The most conspicuous logistic phenomenon of the great 20th-century wars was the enormous quantity of material used and consumed. One cause was the growth of firepower, which was partly a matter of increased rapidity of fire of individual weapons, partly a higher ratio of weapons to men—both multiplied by the vast numbers of troops now mobilized. An American Civil War infantry division of 3,000 to 5,000 men had an artillery complement of up to 24 pieces; its World War II counterpart, numbering about 15,000 men, had 328 artillery pieces, all capable of firing heavier projectiles far more rapidly. A World War II armoured division had nearly 1,000 pieces of artillery. Twentieth-century infantrymen, moreover, were armed with semiautomatic and automatic weapons.

The upward curve of firepower was reflected in the immense amounts of ammunition required in large-scale operations. Artillery fire in the Franco-German War and in the Russo-Japanese War (1904–05), for example, showed a marked increase over that in the American Civil War. But World War I unleashed a firepower hardly hinted at in earlier conflicts. For the preliminary bombardment (lasting one week) in the First Battle of the Somme in 1916, British artillery was provided 23,000 tons of projectiles; 100 years earlier, Napoleon's gunners at Waterloo had about 100 tons. In World War II the United States procured only about four times as many small arms as it had in the Civil War but 43 times as much small-arms ammunition. (To the ammunition expenditures in World War II were added, moreover, the immense tonnages of explosives used in air bombardment.) The Confederacy fought through the four years of the Civil War on something like 5,000 or 6,000 tons of gunpowder, whereas U.S. factories in one average month during World War I turned out almost four times this quantity of smokeless powder. Again, in one year of World War II, seven million tons of steel went into the manufacture of tanks and trucks for the U.S. Army, four million tons into artillery ammunition, one million tons into artillery, and 1.5 million tons into small arms—as contrasted with less than one million tons of pig iron used by the entire economy of the Northern states during one year of the Civil War.

With quantitative growth went a parallel growth in the complexity of military equipment. The U.S. Army in

World War II used about 60 major types of artillery above .60-inch calibre; for 20 different calibres of cannon there were about 270 types and sizes of shells. The list of military items procured for U.S. Army ground forces added up to almost 900,000, each of which contained many separate parts—as many as 25,000 for some antiaircraft guns. To convert and expand a nation's peacetime industry to the production of such an arsenal posed staggering technical problems. Manufacturers of automobiles, refrigerators, soap, soft drinks, bed springs, toys, shirts, and microscopes had to learn how to make guns, gun carriages, recoil mechanisms, and ammunition.

Staged resupply. Long before mechanization relegated local supply to a minor role in logistics, growing supply requirements were making armies more dependent on supply from bases. The *Etappen* system of the Prussian army in 1866 resembled the Napoleonic train service of **Shuttling** 1807. Behind each army corps trailed a lengthening series **supplies** of shuttling wagon trains moving up supplies through a **along a** chain of magazines extending back to a railhead. A small **chain of** train accompanied the troops, carrying a basic load of ammunition, rations, and baggage; each soldier also carried additional ammunition and three days' emergency rations. The system was geared to a steady, slow advance on a rigid schedule and a predetermined route.

Before the advent of mechanization half a century later, the system did not work well, since the shuttling wagon trains were unable to keep up with a rapid advance. In both the Franco-German War and the German invasion of France in 1914, German forces outran their trains and had to live off the French countryside, one of the richest agricultural regions in Europe. In the latter campaign, however, the Germans' tiny motor transport corps played a vital role in supplying ammunition for the opening battles. In subsequent operations on the Western Front, the immobility of the opposing forces provided an ideal environment for the staged resupply system, reversing the ancient rule that a "sitting" army must starve. On the other hand, many offensives on that front bogged down, after gaining only a few miles, through failure to move up quickly the quantities of fuel, ammunition, and supplies needed to maintain momentum.

The staged resupply system, in practice, did not precisely resemble either a pipeline or a series of conveyor belts maintaining a continuous flow from ultimate source to consumer. Reserves were stocked as far forward as was safe and practicable, permitting a regular supply of food and fuel and an immediate provision of ammunition, equipment, and services as needed. Before a major operation, large reserves had to be accumulated close behind the front; the two-year Allied build-up in the British Isles before the Normandy invasion of 1944, for example, involved the shipment of 16 million tons of cargo across the Atlantic. After the invasion, behind the armies on the Continent spread the rear-area administrative zone, a vast complex of depots, traffic regulating points, railway marshaling yards, troop cantonments, rest areas, repair shops, artillery and tank parks, oil and gasoline storage areas, air bases, and headquarters—through which ran the lines of supply stretching back to ultimate sources.

In the Pacific, the administrative zone covered vast reaches of ocean and clusters of islands. Communication and movement in this theatre depended largely on shipping, supplemented by aircraft, and one of the major logistic problems was moving forward bases and reserves as the fighting forces advanced. Supply ships often sailed all the way from the U.S. West Coast, bypassing intermediate bases, to forward areas where they were held as floating warehouses until their cargoes were exhausted.

In a real sense, the basic logistic tools of land operations in World War II were the railroad, the motor truck, and, carried over from the premechanized era, the horse-**Motorized** drawn wagon. Motor transport, when available, served **and horse-** to move forward the mountains of material brought to **drawn** railheads by the railroads—a feat that, as the late 19th-**transport** century wars and World War I had shown, could not be done by horse-drawn vehicles rapidly enough to sustain fast-moving forces. When supplied by motor transport, mechanized armies, particularly in the European theatre,

achieved a mobility and striking power never before seen. Paradoxically, Germany, which dominated operations in this theatre until late in the war, suffered from a severe shortage of motor transport and rolling stock, only partially made good by levies on conquered nations. The Wehrmacht that invaded the Soviet Union in 1941 consisted mainly of slow-moving infantry divisions supplied by horse-drawn wagons and spearheaded by a few armoured and mechanized units racing ahead. In order to maximize the capacity of its meagre motor transport, the organic transport of the armoured spearheads actually backtracked over the route of advance to pick up containerized fuel from prepositioned dumps—a novel modification of the staged resupply system. Motor transport was also supplemented by use of captured Soviet railroads (which had to be converted from wide to narrow gauge to accommodate German rolling stock) extending into the combat zone and paralleling vehicle roads.

The logistics of the North African desert campaigns in World War II virtually eliminated local supply and intermediate bases and depots, in effect replacing staged resupply by a simple single-shuttle base-to-troops operation. In 1941–42 the German Afrika Korps in Libya was supplied across the Mediterranean through the small port of Tripoli and eastward over a single coastal road that had no bases or magazines and was exposed to enemy air attack—a distance of up to 1,300 miles, depending on the location of the front (200 miles was considered the normal limit for effective supply). This operation was occasionally supplemented by small coastal shipments into the ports of Banghāzi and Tobruk. The fuel cost of this overland operation was between one-third and one-half of all the fuel imported.

One of the striking lessons of World War II, often obscured by the tactical achievements of air power and mechanized armour, was the great power that modern logistics gave to the defense. In 1943 and 1944 the ratio of superiority enjoyed by Germany's enemies in output of combat munitions was about 2.5:1; the whole apparatus of Germany's war economy was subjected to relentless attack from the air and had to make good enormous losses of matériel in a succession of military defeats. Yet Germany was able, for about two years, to hold its own, primarily because its waning logistic strength could be concentrated on sustaining the firepower of forces that were stationary or retiring slowly toward their bases, instead of on the expensive effort required to support a rapid forward movement.

Logistic specialization. For many centuries the soldier was a fighting man and nothing else; he depended on civilians to provide the services that enabled him to live, move, and fight. Even the more technical combat and combat-related skills, such as fortification, siegecraft, and service of artillery, were traditionally civilian. After the mid-19th century, with the rather sudden growth in the technical complexity of warfare, the military profession faced the problem of assimilating a growing number and variety of noncombatant skills. Many of the uniformed logistic services date from this period; examples are the British army's Transport Corps (later the Royal Army Service Corps), Hospital Corps, and Ordnance Corps. In the American Civil War the Union army formed a railway construction corps, largely civilian but under military control. A little later, Prussia created a railway section in the Great General Staff and a combined military–civilian organization for controlling and operating the railroads in time of war.

Not until the 20th century, however, did organized military units performing specialized logistic services begin **combat** to appear in large numbers in the field. By the end of **and** World War II, what was called "service support" com-**noncombat** prised about 45 percent of the total strength of the U.S. **personnel** Army. Only three out of every 10 soldiers had combat functions, and even within a combat division one man out of four was a noncombatant. Even so, the specialized services that the military profession succeeded in assimilating were only a small fraction of those on which the combat soldier depended. Throughout the vast administrative zones behind combat areas and in the national

base, armies of civilian workers and specialists manned depots, arsenals, factories, communication centres, ports, and the other apparatuses of a modern society at war. Military establishments employed growing numbers of civilian administrators, scientists, technicians, management and public relations experts, and other specialists. Within the profession itself, the actual incorporation of specialized skills was limited, in the main, to those directly related (or exposed) to combat, such as the operating and servicing of military equipment, though even there the profession had no monopoly. Soldiers also served as administrators and supervisors over civilian specialists with whose skills they had only a nodding acquaintance. On the whole, the fighting man at mid-20th century belonged to a shrinking minority in a profession made up largely of administrators and noncombatant specialists.

Logistics in the nuclear age. The dropping of the first atomic bombs in August 1945 seemed to inaugurate a new era in warfare, demanding radical changes in logistic systems and techniques. The bombs did, in truth, give birth to a new line of weaponry of unprecedented destructive power. Within a decade they were followed by the thermonuclear weapon, an even greater leap in destructive force. Development of intercontinental ballistic missiles and nuclear-powered, missile-firing submarines a few years later extended the potential range of destruction to targets anywhere on the globe. The following decades saw dramatic developments in the offensive capabilities of nuclear weapons and also, for the first time, in defenses

Wars of
limited
scale

against them. But the world moved into the late 20th century without any of the new nuclear weaponry having been used in anger. Most warfare, moreover, was limited in scale and made little use of advanced technology. It produced only nine highly mobilized war economies: the two Koreas (1950–53), Israel (1956, 1967, 1973), North Vietnam (1965–75), Biafra (1967–70), Iran and Iraq (1980–88)—all except Israel preindustrial Third World countries.

The first major conflict in this period, the war in Korea (1950–53), seemed in many ways an extension of the positional campaigns in World War II. It was fought largely with World War II weapons, in some cases improved versions, and with stocks of munitions left over from that conflict. United Nations forces had an excellent base in nearby Japan, whose factories made a major contribution by rebuilding U.S. World War II material. UN air superiority kept both Japan and Pusan, South Korea's major port of entry, free from communist air attack. UN forces thus were able to funnel through Pusan supply tonnages comparable to those handled by the largest ports in World War II and to concentrate depots and other installations in the Pusan area to a degree that would have been suicidal without air superiority. The communist supply system, although technically primitive, functioned well under UN air attack, moving troops and supplies by night, organizing local labour, and exploiting the Chinese soldier's famous ability to fight well under extreme privation.

By World War II standards, the Korean War was a limited conflict (except for the two Korean belligerents, on whose soil it was fought). It involved only a partial, or "creeping," economic mobilization in the United States and a modest mobilization of reserves. Yet this was no small war. Over three years about 37.2 million measurement tons of cargo were poured into the South Korean ports, more than three-fourths of the amount shipped to U.S. Army forces in all the Pacific theatres in World War II. Combined UN forces reached a peak strength of almost one million men; communist forces were considerably larger.

New technology. Advances in the technology of supply and movement after 1945 were not commensurate with those in weaponry. On land, internal-combustion vehicles and railroads, with increasing use of diesel fuel in both, remained the basic instruments of large-scale troop and freight movement despite their growing vulnerability to attack. In the most modern systems, substantial amounts of motor transport were capable of crossing shallow water obstacles. In areas not yet penetrated by rail or metaled roads—areas where much of the warfare of the period occurred—surface movement necessarily reverted to the

ancient modes of human and animal porterage, sometimes usefully supplemented by the bicycle. Some exotic types of vehicles capable of negotiating rough and soft terrain off the roads were designed and tested—the "hovercraft," or air-cushion vehicle, for instance. But none of these innovations came into general use. The most promising developments in overland movement were helicopters and vertical-takeoff-and-landing aircraft, along with techniques of rapid airfield construction, which enabled streamlined airmobile forces and their logistic tails to overlap terrain obstacles and greatly reduced their dependence on roads, airfields, and forward bases. Helicopters also permitted the establishment and maintenance of isolated artillery fire bases in enemy territory.

In air movement there was a spectacular growth in   Jet aircraft
the range and payload capacity of transport aircraft. The piston-engine transports of World War II vintage that carried out the Berlin airlift of 1948–49 had a capacity of about four tons (3,640 kilograms) and a maximum range of 1,500 miles (2,400 kilometres). The U.S. C-141 jet transport, which went into service in 1965, had a 45-ton (40,900-kilogram) capacity and a range of 3,000 miles (4,800 kilometres); it could take an average payload of 24 tons from the U.S. West Coast to South Vietnam in 43 hours and evacuate wounded back to the East Coast (10,000 miles) in less than a day. By 1970 these capabilities were dwarfed by the new "global logistics" C-5A, with payloads up to 130 tons and ranges up to 5,500 miles. It is estimated that 10 C-5As could have handled the entire Berlin airlift, which employed more than 140 of the then-available aircraft. C-5As played a vital role in the U.S. airlift to Israel during the Arab-Israeli War of October 1973. Very large cargo helicopters were also developed, notably in the Soviet Union, as were new techniques for packaging and air-dropping cargo.

In this period, movement by sea was the only branch of logistics that tapped the huge potential of nuclear propulsion. Its principal application, however, was in submarines, which did not develop a significant logistic function. (Development of nuclear-powered aircraft proved abortive.) The Soviet Union produced a nuclear-powered icebreaker in 1957, and the United States launched the first nuclear-powered merchant ship in 1959. But high initial and operating costs and (in the West) vested mercantile interests barred extensive construction of nuclear merchant ships. Except for supertankers built after the Suez crisis in 1956, and again during the energy crisis of the 1970s, seaborne cargo movement still depended on ships not radically different from those used in World War II. The chief technical improvement in sea lift, embodied in a few special-purpose vessels, was the "roll-on-roll-off" feature, first used in World War II landing craft, which permitted loading and discharge of vehicles without hoisting. Containerization, the stowage of irregularly shaped freight in sealed, reusable containers of uniform size and shape, became widespread in commercial ship operations and significantly affected ship design.

This period saw further development, from World War II models, of large vessels capable of discharging landing craft and vehicles offshore or over a beach as well as transporting troops, cargo, and helicopters in amphibious operations. For follow-up operations, improved attack cargo ships were built, such as the British landing-ship logistic, with accommodations for landing craft, helicopters, vehicles and tanks, landing ramps, and heavy-cargo-handling equipment. More revolutionary additions to the technology of amphibious logistics were the American landing vehicle hydrofoil and the BARC, both amphibians with pneumatic-tired wheels for overland movement and, in the latter case, capacity for 100 tons of cargo. Hydrofoil craft, which skimmed at high speeds above the water on submerged inclined planes, developed a varied family of types by 1970.

The revolution in electronic communication after World   Electronic
War II lies beyond the scope of this article, but its pro-   communi-
found impact on logistic administration should be noted.   cation and
In advanced logistic systems the combination of advanced   computers
electronic communication with the high-speed electronic computer almost wholly replaced the elaborate processes

of message transmission, record search, and record keeping formerly involved in supply administration, making the response of supply to demand automatic and virtually instantaneous.

Strategic mobility. Because the leading military powers did not directly fight each other during the decades after World War II, none of them had to deal with the classic logistic problem of deploying and supporting forces over sea lines of communication exposed to enemy attack. The Soviet Union was able in 1962 to establish a missile base in Cuba manned by some 25,000 troops without interference by the United States until its offensive purpose was detected. Similarly, the large deployments of U.S. forces to Korea, Southeast Asia, and elsewhere, as well as the 8,000-mile movement of a British expeditionary force to the Falkland Islands in 1982, encountered no opposition.

Supplying forces at global distances

Yet the problem of strategic mobility was of major concern after 1945 to the handful of nations with far-flung interests and the capacity to project military power far beyond their borders. In the tightly controlled power politics of the period, each of these countries needed the capability to bring military force quickly to bear to protect its interests in local emergencies at remote points—as Great Britain and France did at Suez in 1956, the United States in Lebanon in 1958 and in the Taiwan Straits in 1959, Great Britain in Kuwait in 1961 and in the Falkland Islands in 1982, and France in Chad on several occasions in the 1980s. The most effective instruments for such interventions were small, powerful, mobile task forces brought in by air or sea as well as forward-deployed aircraft-carrier and amphibious forces. The United States developed strong and versatile intervention capabilities, with major fleets deployed in the far Pacific and the Mediterranean; a worldwide network of bases and alliances; large ground and air forces in Europe, Korea, and Southeast Asia; and, in the 1960s, a mobile strategic reserve of several divisions with long-range sea-lift and airlift capabilities. The Soviet Union, Great Britain, and France had more limited capabilities, although the Soviet Union began in the late 1960s to deploy strong naval and air forces into the eastern Mediterranean and also maintained a naval presence in the Indian Ocean. After the U.S. withdrawal from Vietnam in 1973, the Soviet navy extended its power into the South China Sea.

The logistics of strategic mobility was complex and was decisively affected by the changing technology of movement, especially by air and sea. During the 1950s the proponents of naval and land-based air power debated the relative cost and effectiveness of naval-carrier forces and fixed air bases as a tool of emergency intervention. Studies seemed to show that the fixed bases were cheaper if all related costs were considered but that the advantage of mobility and flexibility lay with the naval carriers. In the 1970s the growing range and capacities of transport aircraft provided an increasingly effective tool for distant intervention and were a large factor in the reduction of the American and British overseas base systems. In practice, emergency situations called for using the means available and involved a great deal of improvisation, especially for second-rank powers.

Management. Both during and after World War II the United States operated the largest and most advanced logistic system in the world. Its wartime operations stressed speed, volume, and risk-taking more than efficiency and economy. The postwar years, with accelerated technological change, skyrocketing costs, and diminished public interest in defense, brought a revulsion against military prodigality, manifested by calls for reduced defense budgets and a growing demand for more efficient management of the military establishment. This demand culminated in a thorough overhaul of the whole system in the 1960s.

Introduction of modern managerial techniques and systems

One result was the reorganization of logistic activities in the three military services, generally along functional lines, with large logistic commands operating under functional staff supervision. In each service, however, each major weapon system was centrally managed by a separate project officer, and central inventory control was maintained for large commodity groups. In 1961 a new defense supply agency was established to manage on a wholesale basis

the procurement, storage, and distribution of common military supplies and the administration of certain common services.

The most far-reaching managerial reforms of the period were instituted by the U.S. defense secretary, Robert S. McNamara (1961–68), in the resource allocation process. A unified defense planning–programming–budgeting system provided for five-year projections of force, manpower, and dollar requirements for all defense activities, classified into eight or nine major programs (such as strategic forces) that cut across the lines of traditional service responsibilities. The system was introduced in other federal departments after 1965, and elements of it were adopted by the British and other governments. In 1966 a program was inaugurated to integrate management accounting at the operating level with the programming–budgeting system. At the end of the 1960s a new administration restored some of the initiative in the planning–budgeting–programming cycle to the Joint Chiefs of Staff and the military services.

The reforms of the 1960s exploited the whole range of current managerial methodology. The basic techniques, such as systems and operations analysis, all stressed precise, scientific, usually quantitative formulations of problems and mathematical approaches to rational decision making. Systems analysis, the technique associated with defense planning and programming, was a method of economic and mathematical analysis useful in dealing with complex problems of choice under conditions of uncertainty. The technological foundation of this improved logistic management was the high-speed electronic computer, which was being used chiefly in inventory control; in automated operations at depots, bases, and stations; in transmitting and processing supply data; in personnel administration; and in command-and-control networks.

War in Vietnam. One of the most significant developments in logistics after 1945 was the pitting of advanced high-technology systems against well-organized low-technology systems operating on their own ground. The Korean War and the anticolonial wars in French Indochina and Algeria were the principal conflicts of this kind in the 1950s. The war in Vietnam following large-scale U.S. intervention in 1965 brought into conflict the most effective of both types of systems.

Scale of the U.S. logistic effort

Because South Vietnam lacked most of the facilities on which modern military forces depend, the massive U.S. deployment that began in the spring of 1965, reaching 180,000 men by the end of that year and more than 550,-000 in 1969, was accompanied, rather than preceded, by a huge ($4 billion) construction program, carried out partly by army, navy, and air force engineer units and partly by a consortium of engineering contractors. Under this program were built seven deepwater and several smaller ports, eight jet air bases with 10,000-foot (3,050-metre) runways, 200 smaller airfields, and 200 heliports, besides millions of square feet of covered and refrigerated storage, hundreds of miles of roads, hundreds of bridges, oil pipelines and tanks, and all the other apparatuses of a modern logistic infrastructure. Deep-draft shipping brought in all but scarce items of airlifted supplies and came mainly from the U.S. directly.

The soldier in the field received lavish logistic support. By means of helicopter supply, troops in contact with the enemy were often provided with hot meals; most of the wounded were promptly evacuated to hospitals and serious cases were moved by air to base facilities in the Pacific or the United States. Medical evacuation, combined with advances in medicine, helped to raise the ratio of surviving wounded to dead to 6:1, in contrast to a World War II ratio of 2.6:1. Logistic support of army forces was organized under a single logistic command having a strength of 30,000 and employing 50,000 Vietnamese, U.S., and foreign civilians. Ultimately there were four or five support personnel for every infantryman who bore the brunt of contact fighting with the enemy.

The communist logistic system centred in the highly mobilized society of North Vietnam. In its integration, efficiency, and resilience under concentrated and prolonged bombing it rivaled the war economy of Germany

in World War II. Its resilience owed much, however, to its being a village-centred agricultural society, with modest material needs and a limited industrial base, which produced no steel, very little pig iron, and only one-fifth as much electric power as a single power plant in a small American town.

By late 1967 the communist war effort in South Vietnam depended heavily on the flow of troops, equipment, and supplies from North Vietnam, supplied mainly by the Soviet Union. The troops and most of the supplies moved over the Ho Chi Minh Trail, originally a network of footpaths and dirt roads (often paved after 1967) through communist-controlled areas in Laos and Cambodia. Supplies also came into South Vietnam by sea, directly across the northern border, and, especially after 1967, through the Cambodian port of Kompong Som and overland into the Mekong delta.

The Ho
Chi Minh
Trail

The Ho Chi Minh Trail was a long, slow-moving pipeline, requiring from three to six months in transit by truck, barge, ox cart, bicycle, and foot, but its capacity was ample for the modest demands placed upon it. In mid-1967, U.S. intelligence estimated the total nonfood requirements of all communist forces in South Vietnam, except in the northernmost provinces, to be as low as 15 tons (13,640 kilograms) per day (about 1.5 ounces, or 43 grams, per man); food was procured locally and in nearby Cambodia and Laos. In 1968, when the pace of the war quickened and communist forces were substantially augmented, estimated nonfood requirements rose to about 120 tons per day. (A single U.S. division required about five times this amount.)

American bombing had little effect on the flow of troops to the south, and the communist logistic system stood up remarkably well—and ultimately victoriously—under the weight of American air power. Its strength lay primarily in its austerity, but also in efficient organization, lavish use of manpower, availability of sanctuary areas in Laos and Cambodia, and a steady flow of imported supplies.

Afghanistan. The Soviet Union's Afghan war (1979–89), though on a scale smaller than Vietnam, embodied similar political, social, and economic dynamics and a similar contest between high-technology and low-technology logistic systems. Soviet forces, concentrated in the principal cities and towns, relied heavily on airlift and convoyed motor transport to move troops and supplies. Afghan guerrillas (called mujahideen), holding most of the countryside, used mainly animal transport and brought much of their supplies and weapons across the border from Pakistan. In an agriculturally poor country, significantly depopulated by Soviet bombing and forced flight into Pakistan, mass hunger and disease were widespread. For most of the war an approximate stalemate prevailed, in logistics as well as in tactical operations. But in 1986 the acquisition from the United States and Great Britain of substantial numbers of shoulder-fired surface-to-air missiles enabled the mujahideen to challenge Soviet control of the air—a significant factor in the Soviets' withdrawal early in 1989.

Trends and prospects. For logisticians the fundamental dilemma posed by the quantum leap in weapons technology after World War II was the absence of any comparable development in logistics. The electronic computer had, indeed, a dramatic impact on logistic planning and administration, as well as on military administration in general. The computer enabled planners to visualize problems concretely, often in quantitative terms; it accelerated the transmission of demand and the administrative response to it; and it enabled the military services for the first time to control their inventories. But the computer could not touch the ancient problem, compounded by the new weaponry, of actually providing and moving supplies to their users.

Conversely, nuclear weapons threatened to sweep away every vestige of the logistic system of the industrial era. None of the elaborate apparatuses of rear-area administration, lines of communication, or even sources of supply seemed likely to survive the nuclear firepower that could be brought to bear against it. The problem was studied and restudied, and a great deal of hopeful doctrine was devel-

Logistics
in a
nuclear
war

oped for logistic operations in a nuclear war. It revolved about such concepts as dispersion, mobility, small targets, duplication, multiplicity, austerity, concealment, and automaticity, yet all of it was little more than a planner's dream, and a fading dream at that. At best it promised to reduce somewhat the inherent vulnerability of the surface-bound installations and transport on which military forces for the foreseeable future were likely to depend. Dispersion and duplication were enemies of economy and efficiency. The net effect could only be to increase the costs of logistic support and diminish the yield of delivered supplies and services.

In any case, nuclear war seemed the least likely of prospects. The most likely appeared to be a continuation of the confused patterns of limited conventional war and quasi-war that had filled the decades since the end of World War II. Under these conditions the central problems of logistics would be the historic ones of weight and bulk, which inhibited mobility and range of movement and were the primary causes of vulnerability to the new firepower. The technologies of these decades had accelerated the basic logistic trends of the industrial era: increasing complexity and cost in military hardware, increasing overall weight and volume of material (despite a reverse trend toward reduced numbers in some major items, such as aircraft), and, above all, an enormous increase in expenditures of ammunition and fuel. Logisticians in the postwar decades had to face the probability that in another large-scale conventional conflict between advanced powers the new vehicles would consume about half again as much fuel and the new weapons would expend more than four times as much ammunition as had been consumed and expended in World War II.

Some of the new tools of logistics were highly effective in specialized environments, notably the growing family of helicopters used in conjunction with conventional and short-takeoff-and-landing air transports, which permitted a mobility and a range of movement over difficult terrain far beyond the capabilities of surface transport. Whether an airmobile logistic system could survive the firepower likely to be encountered in a conflict with an adversary disputing command of the air was a question to which experience had not yet given an answer. In any case, the system purchased its mobility and range at a fuel cost several times higher than that involved in surface transport.

The
unprece-
dented
threat to
supply
lines

How well the "sophisticated" systems, with their growing burden of weight and bulk, would function under a threat to their previously immune supply lines was perhaps the most serious challenge facing modern logisticians. Nuclear propulsion offered a theoretical solution, but there seemed little hope for its early application to large sectors of military movement. A nuclear-powered sea transport service was a reasonable prospect, though not an early one, and it would not suffice for a major overseas war. More fundamentally, fuel consumption on the sea lanes was not the crux of the problem, and nuclear propulsion offered no solution to the vulnerability of surface vessels to air and submarine attack. The massive fuel consumers were aircraft and ground vehicles, and serious technical obstacles barred the application of nuclear energy to their power plants.

The reckoning, if there was to be one, might be long postponed. Given the existing distribution and equilibriums of power among the advanced nations, on the one hand, and the high cost and slow diffusion of sophisticated military technology to the less-developed two-thirds of the world, on the other, limited warfare seemed likely for a long time to come to remain at relatively low technical levels. Meanwhile, sophisticated logistic systems were becoming more entangled in their own complexity and absorbed in the endless pursuit of efficient management and in the struggle to control the waste and friction involved in delivering the tools of war to their users.   (R.M.Le.)

Intelligence

Military intelligence is as old as warfare itself. Even in biblical times, Moses sent spies to live with the Canaanites in order to learn about their ways and about their

strengths and weaknesses. In the American Revolution George Washington relied heavily on information that was provided by an intelligence net based in New York City, and in World War II the results of a lack of good intelligence were realized in the destruction of the U.S. Pacific fleet at Pearl Harbor.

Today, nations have at their disposal information collection and processing systems that permit gathering and producing intelligence more rapidly and more accurately than ever before. Satellites, ultramodern aircraft, electronic systems, human sources, cameras, imaging and electronic devices, and a host of other systems permit the amassing of information on a scale that was unheard of in the past.

LEVELS OF INTELLIGENCE

Strategic and tactical intelligence

Intelligence is conducted at two levels, strategic and tactical. Strategic intelligence is information that is needed to formulate policy and military plans at the international and national policy levels. Tactical intelligence is intended primarily to respond to the needs of military field commanders so they can plan for and, if necessary, conduct combat operations. Essentially, tactical intelligence and strategic intelligence differ only in scope, point of view, and level of employment.

Whether tactical or strategic, military intelligence attempts to respond to or satisfy the needs of the operational leader, the person who has to act or react to a given set of circumstances. The process begins when the commander determines what information is needed to act responsibly. Several terms are used when discussing these requirements. On the national level they are usually called the essential elements of information and are defined as those items of intelligence information about a foreign power, armed force, target, or physical environment that are absolutely vital for timely and accurate decision making. On the tactical level intelligence needs are defined in a similar manner; often called information requirements, they are those items of information concerning the enemy and his environment that must be collected and processed in order to meet the intelligence needs of the military commander.

SOURCES OF INTELLIGENCE

It is critical for the intelligence analyst to know the source of information. Depending on the nature of a problem, certain sources are of great value and are therefore considered of high quality, while other sources, although contributing to the production of intelligence, are supportive rather than critical in nature.

Following are the major sources of intelligence.

Acoustics. This is information derived from analyzing acoustic waves that are radiated either intentionally or unintentionally. In naval intelligence, underwater acoustic waves from surface ships and submarines are detected by sonar arrays. These sensors are extremely accurate and are a major source of information on submarines in the world's oceans.

Imagery. This is information gleaned from analyzing all types of imagery, including photography as well as infrared and ultraviolet imagery. The examination of imagery, called imagery interpretation, is the process of locating, recognizing, identifying, and describing objects, activities, and terrain that appear on imagery.

Imagery collected by satellites and high-altitude aircraft is one of the most important sources of intelligence. It not only provides information for a huge number of intelligence categories (such as order of battle, military operations, scientific and technical developments, and economics), but it is indispensable for successfully monitoring compliance with arms-limitation treaties. The Intermediate Nuclear Forces Treaty of 1987 allows the United States periodically to request that the Soviet Union open certain intercontinental ballistic missile sites so that U.S. satellites (referred to as "national technical means") can verify that the sites do not house intermediate-range missiles banned by the treaty.

Tactical infrared imaging devices can often identify camouflaged tanks and armour because the materials used to cover them—trees, branches, and leaves—often register different infrared signatures than does the surrounding

Monitoring compliance with treaties

foliage. Infrared satellites can register heat through clouds, producing imagery on enemy forces, equipment, and movements.

Signals. Gained from intercepting, processing, and analyzing foreign electrical communications and other signals, signals intelligence (often called SIGINT) comprises three elements: communications, electronics, and telemetry.

Communications intelligence is gleaned from foreign communications that are intercepted by other than the intended recipients. Such intelligence can be of the greatest value to a nation's fighting forces because it allows them to be privy to the strategies, weaknesses, and attitudes of the enemy. For example, before and during World War II, the U.S. Navy's breaking of the Japanese PURPLE code allowed the United States to know of Japanese moves in advance. It even provided warning of the attack on Pearl Harbor, although this intelligence was not sent to Hawaii quickly enough to prevent the debacle.

Electronics intelligence (also called ELINT) is technical and intelligence information obtained from foreign electromagnetic emissions that are not radiated by communications equipment or by nuclear detonations and radioactive sources. By analyzing the electronic emissions from a given weapon or electronic system, an intelligence analyst can very often determine the purpose of the device.

Telemetry intelligence is technical information that is derived from intercepting, processing, and analyzing foreign telemetry data. For example, by intercepting the telemetry signals emitted during foreign ballistic missile tests, an intelligence agency can calculate the range, accuracy, and number of warheads of the weapon.

Radiation. This source of intelligence does not include energy emanating from nuclear detonations or radioactive sources. Rather, it concerns unintentional emissions of energy from electronic systems (while ELINT is based on intentional radiations from the same systems). Inadequate shielding of electronic systems, or the following of incorrect procedures, may result in inadvertent energy emissions, which, when analyzed, may reveal a great deal about a system's purpose or capabilities.

Foreign matériel. In 1976 a Soviet air force lieutenant, wishing to defect to the West, flew a MiG-25 Foxbat to Japan, where Japanese and U.S. technicians pored over every detail of the supersonic fighter before reassembling it and handing it back to its owners. Such analysis of a foreign weapon system can prove invaluable in producing systems to defeat it, and intelligence derived from any foreign matériel is of great value in assessing enemy capabilities.

Analyzing foreign weapons

Human agents. Often called HUMINT, human intelligence is provided by people rather than by technical means and is very often provided by spies and covert agents. Spies are often a prime source of information about a nation's political leaders, strategies, and political decisions. The Soviet colonel Oleg Penkovsky, for example, was a very important source for British and U.S. intelligence until he was arrested and executed in 1963. The political, scientific, and technical information he provided included data on the capabilities of Soviet intermediate-range missiles during the Cuban missile crisis. Likewise, the Philby–Burgess–Maclean spy ring, which penetrated the highest circles of Britain's MI-6 intelligence agency, provided the Soviets with a tremendous amount of information on British and Allied military and counterintelligence operations during and after World War II. In the United States, the Walker family sold the Soviet Union classified reports on the tracking of Soviet submarines and surface ships. Operating from 1968 until it was broken up in 1985, this spy ring did irreparable damage to the submarine warfare capabilities of the U.S. Navy.

TYPES OF INTELLIGENCE

In most situations, intelligence production involves the assessment of conflicting pieces of incomplete information, the attempt to determine the correct items, and then the processing and assembly of these accurate items into a complete, understandable document that responds to the needs of the operational leader. More often than not the resulting product, which is usually called an intelligence

appraisal or intelligence assessment, contains some incorrect information.

In order to structure this production, analysts divide intelligence into types. While all types of intelligence are valuable, in any given situation some may be of greater worth than others, may be more accurate, and may provide a more complete view of the situation. By dividing intelligence into types, analysts and commanders arrive at a better understanding of the value and accuracy of a given piece of information.

Following are some important types of intelligence.

Armed forces.   Information on a potential enemy's armed forces—that is, personnel, training, equipment, bases, capabilities, manpower levels, disposition, readiness, and other factors pertaining to strength and effectiveness—is crucial for a nation that is about to enter combat. If the weaknesses can be exploited, then the conflict may be won more quickly and with fewer casualties. Toward the end of World War II, owing to incomplete intelligence it was predicted that Japan would fight resolutely against a U.S. invasion and that the United States might suffer up to one million casualties. This was a major factor in the decision to drop the atomic bomb on Hiroshima and Nagasaki. In reality, though, Japanese resolve was grossly overestimated, and Japan could probably have been conquered with far fewer Allied casualties.

Assessing an enemy's strengths and weaknesses

Biographical.   This is information collected on the views, traits, habits, skills, importance, relationships, health, and professional history of the leaders and important individuals of a nation. Biographical intelligence is important to those who must decide whether to support a foreign leader. For example, when Fidel Castro first came to power in Cuba in 1959, he claimed to be a nationalist and was even allowed to conduct a speaking tour in the United States. Subsequently, however, Castro revealed that he was a communist who intended to transform Cuba into a Soviet-style state. More accurate intelligence on Castro might have revealed his intentions more promptly, and U.S. foreign policy could have been revised accordingly.

In clandestine operations, one of the most difficult problems is assessing the validity of an individual who volunteers his services to an intelligence organization. Very often, information on the family life, education, travels, and professional and political affiliations of such a person provides great insight into motivation and can help in verifying authenticity.

Cartographic.   Derived from maps and charts, cartographic intelligence is crucial for all military operations. During the Falkland Islands War, for example, British forces depended heavily on cartography. They also interviewed schoolteachers and scientists who had recently left the islands so that they had the most accurate information possible on road conditions, towns, and facilities. This prepared invading troops to meet the obstacles caused by rough terrain and poor roads, and as a result the invasion went remarkably well.

Economic.   This is information concerning the production, distribution, and consumption of goods and services, as well as labour, finance, taxation, and other aspects of a nation's economy or of the international economic system. Economic intelligence allows a nation to estimate the magnitude of possible military threats and is also valuable in estimating the intentions of a potential enemy. In wartime, economic intelligence is a prime indicator of an enemy's ability to sustain a war. This is particularly important when analyzing small nations, such as Israel, where a conflict requires total mobilization and cannot be sustained for long without creating severe economic problems.

Energy.   Energy intelligence specifically addresses the location and size of foreign energy resources; how these resources are used and allocated; foreign governments' energy policies, plans, and programs; new or improved foreign energy technologies; and the economic and security aspects of foreign energy supply, demand, production, distribution, and use.

Energy requirements can be an important factor in military planning. For example, as German forces were advancing on Moscow during World War II, Hitler, on being informed that the German military was short of fuel, sent several of the advancing units southward to capture the oil complexes at Baku on the Caspian Sea. This move so depleted the forces advancing on Moscow that they failed to capture the city, dealing the German war effort a fatal setback. Later, on the Western Front, advancing Allied forces were so short of fuel that U.S. general George Patton's 3rd Army was forced to stop and await replenishment. This allowed the retreating Germans to dig in and prolong the war.

Counterintelligence.   Counterintelligence is intended to detect, counteract, and prevent espionage and other clandestine intelligence activities, sabotage, terrorist attacks, or assassinations conducted on behalf of foreign powers, organizations, or persons. It is especially vital that nations identify the capabilities and intentions of international terrorist organizations so that their operations can be thwarted; in the event that a terrorist attack is successful, identifying the culprit allows for reprisals, which are crucial to combating terrorism. In December 1988 an American commercial aircraft was destroyed over Scotland, and neither the United States nor Great Britain initially could identify the terrorist organization involved. As a result, the act was successful from the perspective of the terrorists, who had injured their enemy without suffering retaliation.

Preventing or reacting to attacks

Geographic.   Gained from studying natural characteristics including terrain, climate, natural resources, transportation, boundaries, and population distribution, military geographic intelligence involves evaluating all such factors that in any way influence military operations.

Geographic intelligence was crucial to the success of Israel's rescue mission at the Entebbe airport in Uganda in 1976. Because they had reliable information on the exact location of the buildings at the airport, of the roads leading to Entebbe, and of military bases in the region, Israeli soldiers were able to land in three transport planes, kill many of the terrorists holding Israeli hostages, and depart with most of the hostages before the Ugandan military could react. A significant factor in the disastrous U.S. attempt to rescue its hostages in Iran in 1980 was a failure to anticipate and prepare for seasonal sandstorms, which disabled several helicopters and forced the rescuers to abort their mission.

Medical.   This is intelligence gained from studying every aspect of foreign natural and man-made environments that could affect the health of military forces. This information can be used not only to predict the medical weaknesses of an enemy but also to provide one's own forces with adequate medical protection. For example, in the Spanish-American War the majority of U.S. casualties in the Caribbean resulted from disease rather than combat, because U.S. forces were not prepared to deal with the environment of that region.

Sociological.   Information on a nation's social stratification, value systems, beliefs, and other social characteristics are of crucial value in assessing nations such as South Africa, the Soviet Union, or Israel, where national, racial, or social factions can have a great impact on a nation's military capability.

A lack of good sociological intelligence was a major cause of U.S. blunders in dealing with revolutionary Iran. When Mohammad Reza Shah Pahlavi was overthrown in 1979, the United States had only the most superficial understanding of Islām and Iranian society, and the situation improved only slightly in subsequent years. As a result, the United States often remained ignorant about Iranian officials, calling them "radical" or "moderate" even when such terms did more to cloud a situation than to make it clear.

Transportation and telecommunication.   This type of intelligence can be crucial to correctly assessing a nation's ability to wage war, as it concerns a nation's highways, railroads, inland waterways, and civil airways as well as its telephone, telegraph, and civil broadcast capabilities. When China sent troops across the border into Vietnam in 1979, many observers assumed that China would win the conflict. This estimate was based on the huge size of the Chinese army and on its excellent performance against United Nations forces in the Korean War. After China

The enemy's ability to wage war

failed to score a decisive victory, the same commentators examined China's transportation and telecommunication networks and found that, while they were very highly developed in the Northeast, they were quite primitive in the South. It was concluded that the advanced northeastern systems and the primitive southern systems were prime factors in China's success in Korea and in its lackluster performance in Vietnam. (B.W.Wa.)

Guerrilla warfare

Guerrilla warfare is characterized by irregular forces employing unorthodox military tactics to fight small-scale, limited actions against orthodox civil and military forces. Traditionally, it is a method of protest employed to rectify real or imagined wrongs levied on a people either by a foreign invader or by an incumbent government, but it has also been used in an offensive role, in both ancient and modern times.

Although this type of warfare is as old as history, the word *guerrilla* (the diminutive of Spanish *guerra,* "war") stems from the Duke of Wellington's campaigns during the Peninsular War (1808–14), in which Spanish and Portuguese irregulars, or *guerrilleros* (also referred to at the time as "partisans," "insurgents," and "bandits"), helped to drive the French from Iberia. In World War II the word *partisan* became synonymous with *guerrilla;* in later years the word *insurgent* came into vogue, and in parts of the Muslim world, the terms *fedayee* and *mujahid* were used.

Spanish guerrilleros

HISTORY

In 512 BC the Persian warrior-king Darius I, who ruled the largest empire and commanded the best army in the world, bowed to the hit-and-run tactics of the nomadic Scythians and left them to their lands beyond the Danube. Alexander the Great (356–323 BC) also fought serious guerrilla opposition, which he overcame by modifying his tactics and by winning important tribes to his side. In 218 BC Hannibal faced considerable guerrilla opposition in crossing the Alps into Italy; he was later brought to bay by the delaying military tactics of Quintus Fabius Maximus, from whom the term Fabian tactics is derived and who earned the surname Cunctator (meaning "Delayer"). The Romans themselves fought against guerrillas in their conquest of Spain for more than 200 years before the foundation of the empire.

Guerrilla and quasi-guerrilla operations were employed in an aggressive role in ensuing centuries by such predatory barbarians as the Goths and Huns, who forced the western Roman Empire onto the defensive; by the Magyars, who conquered Hungary; by the hordes of northern barbarians who attacked the eastern Roman Empire for more than 500 years; by the Vikings who overran Ireland, England, and France; and by the Mongols, who conquered China and terrified central Europe. In the 12th century the Crusader invasion of Syria was at times stymied by the guerrilla tactics of the Seljūq Turks, an experience shared by the Normans in their conquest of Ireland (1169–75). A century later, Kublai Khan's army of Mongols was driven from Vietnam by Tran Hung Dao, who had trained his army to fight guerrilla warfare. King Edward I of England struggled through long, hard, and expensive campaigns to subdue Welsh guerrillas; that he failed to conquer Scotland was largely due to the brilliant guerrilla operations of Robert the Bruce (Robert I). Bertrand du Guesclin, a Breton guerrilla leader in the Hundred Years' War (1337–1453), all but pushed the English from France by using Fabian tactics of harassment, surprise, ambush, sudden assault, and slow siege.

Guerrillas allied with conventional armies

Guerrilla warfare in time became a useful adjunct to larger political and military strategies—a role in which it complemented orthodox military operations both inside enemy territory and in areas seized and occupied by an enemy. Early examples of this role occurred in the first two Silesian Wars (1740–45) and in the Seven Years' War (1756–63), when Hungarian, Croatian, and Serbian irregulars (called *Grenzerer,* "border people"), fighting in conjunction with the Austrian army, several times forced Frederick II the Great of Prussia to retreat from Bohemia

and Moravia after suffering heavy losses. Toward the end of the U.S. War of Independence (1775–83), Francis ("Swamp Fox") Marion's ragtag band of South Carolina irregulars relied heavily on terrorist tactics to play a major role in driving the British general Charles Cornwallis from the Carolinas to defeat at Yorktown, Va. Wellington's operations in Spain were frequently supported by effectively commanded regional bands of guerrillas—perhaps 30,000 in all—who made life miserable for the French invaders by blocking roads, intercepting couriers, and at times even waging conventional war. In 1812 Napoleon's columns suffered thousands of casualties in the long retreat from Moscow inflicted by bands of Russian peasants working with mounted Cossacks.

Guerrilla wars flourished in the following two centuries as native irregulars in India, Algeria, Morocco, Burma, New Zealand, and the Balkans tried, usually in vain, to prevent colonization by the great powers. Indian tribes in North America viciously fought the opening of the West; Cuban guerrillas fought the Spanish, and Filipino guerrillas fought the Spanish and Americans. In the South African War (1899–1902), 90,000 Boer commandos held off a large British army for two years before succumbing.

As these vicious campaigns continued, political motivations became more and more important. The Taiping Rebellion in China (1850–64), a peasant uprising against the Ch'ing dynasty, killed an estimated 20 million Chinese before it was suppressed. During the American Civil War, mounted guerrillas from both sides raided behind enemy lines. Mexican peasants, fighting under such leaders as Emiliano Zapata, used guerrilla warfare to achieve a specific political goal in the Mexican Revolution (1910–20). Arab tribesmen under Fayṣal I employed T.E. Lawrence's brilliant guerrilla strategy and tactics in their campaign to liberate their lands from the Turks in World War I. In 1916 the Easter Rising in Ireland led to a ferocious guerrilla war fought by the Irish Republican Army (IRA)—a war that ceased only with the uneasy peace and partition of Ireland in 1921. In 1927 a 33-year-old communist leader in China, Mao Zedong (Mao Tse-tung), raised the flag of a rural rebellion that continued for 22 years. This experience resulted in a codified theory of protracted revolutionary war, Mao's *On Guerrilla Warfare* (1937), which was later called "the most radical, violent and extensive theory of war ever put into effect."

The political factor

Political ideology became a more pronounced factor in the numerous guerrilla campaigns of World War II. In most of the countries invaded by Germany, Italy, and Japan, communists either formed their own guerrilla bands or joined other bands, such as the French and Belgian maquis. While consolidating their hold on the country, some of these groups spent as much time eliminating indigenous opposition as they did in fighting the enemy, but most of them contributed sufficiently to the Allied war effort to be sent shipments of arms, equipment, and gold, which gave them the strength to challenge existing governments after the war.

In Yugoslavia and Albania the communist takeover of government was simple and immediate; in China it was complicated and delayed; in South Vietnam it succeeded after nearly three decades; in Greece, Malaya, and the Philippines it was foiled—but only after prolonged and costly fighting. Noncommunist insurgents simultaneously used guerrilla warfare, with heavy emphasis on terrorist tactics, to help end British rule in Palestine in 1948 and Dutch rule in Indonesia in 1949.

Mao Zedong's victory in China in 1949 established him as the prophet of "revolutionary warfare" who had transferred Marxism-Leninism from the industrial areas to the countryside. A spate of new insurgencies, both communist and noncommunist, followed to end French rule in Algeria and Indochina and British rule in Kenya, Cyprus, and Rhodesia. Fidel Castro's overthrow of the tottering and corrupt Batista regime in Cuba in 1959 provoked other rural insurgencies throughout Latin America, Asia, the Middle East, East Asia, and Africa. Ho Chi Minh's guerrillas ejected the French from Indochina, then held off U.S. forces in South Vietnam until the orthodox armies of North Vietnam claimed final victory in 1975. In 1975

guerrilla insurgencies in Angola and Mozambique ended Portuguese rule in those countries. Meanwhile, insurgencies got under way in virtually every corner of the world. Many of these conflicts were directly or indirectly supported by one of the Cold War adversaries.

Beginning in the late 1940s and early '50s, Israel became the target of a protracted guerrilla campaign waged chiefly by groups of Palestinian refugees known as fedayeen, most of whom were associated with the Palestine Liberation Organization (PLO). Israeli operations in Lebanon against the PLO in the early 1980s led to the rise of Hezbollah, a Lebanese Shī'ite group, which began its own guerrilla campaign against the Jewish state.

During the Afghan War (1979–92) a coalition of Muslim guerrillas known as the mujahideen fought a protracted campaign against Afghan government forces and the Soviet army but were heavily subsidized from foreign sources, especially the United States. The Soviets withdrew from that country in 1989, and guerrilla combat continued between various factions thereafter.

South Africa similarly was forced to relinquish control of South West Africa (now Namibia) in 1989, and guerrilla activity by the African National Congress (ANC)—perhaps the most successful guerrilla operation of the modern era—was largely responsible for the end of the apartheid system and for the institution of universal suffrage in South Africa in 1994.

From the country to the cities

In the early 1970s the general failure of rural insurgencies in Central and South America caused some frustrated revolutionaries to shift from rural to urban guerrilla warfare with emphasis on terrorist tactics. Fired by the quasi-anarchistic teachings of Herbert Marcuse, Régis Debray, and others and armed with a do-it-yourself manual of murder (Carlos Marighela, *For the Liberation of Brazil* [1970]), New Left revolutionaries embraced assassination, robbery, indiscriminate bombing, and kidnapping to attain their ends—crimes that became the order of the day as did, on an international scale, airplane hijackings, kidnappings, and mass murder.

Such was the media-heightened impact of urban guerrilla warfare, and such its potential danger to civilized society, that some observers believed "urban terrorism" should be classified as a new genre of warfare. But terrorist tactics, urban or rural, have always been integral to guerrilla and counterguerrilla warfare, indeed to all warfare. ("Kill one, frighten 10,000," wrote the Chinese general Sun-tzu in 350 BC.) In addition, urban guerrilla warfare by itself accomplished virtually nothing except to bring on a host of repressive measures to combat it. A more serious menace to society came from fringe advocates and practitioners of urban and international terrorism, groups of social dropouts far removed from guerrilla insurgencies.

Examples of such groups in the 1970s and '80s were the Black Panther Party, the Weathermen, and the Symbionese Liberation Army in the United States, the Japanese Red Army, the Red Army Faction in West Germany, the Angry Brigade in Great Britain, the Red Brigades of Italy, Direct Action in France, and Middle Eastern groups such as the Popular Front for the Liberation of Palestine-General Command and the Abū Niḍāl Group.

In the post-Cold War era, new groups developed without the ideological ties to either East or West. The development of these new organizations was already apparent during the mid to late 1980s, with the rise of such groups as Hezbollah in Lebanon, Ḥamās and Islāmic Jihad in the occupied territories of the West Bank and Gaza Strip, the Kurdish Workers' Party in Turkey, the Liberation Tigers of Tamil Eelam in Sri Lanka, and the transnational group al-Qaeda. Such entities mixed classical guerrilla tactics with acts of terrorism, such as the September 11 attacks in 2001 perpetrated by al-Qaeda. This attack led to a U.S.-led invasion of Afghanistan (2001) in pursuit of al-Qaeda.

PRINCIPLES

Purpose and motivation. The guerrillas' cause may assume several guises: to the world it may be presented as liberating a country from a colonial yoke; to the peasant being converted to communism it may be freedom from serfdom, from oppressive taxation, or from payment of oppressive rents to absentee landlords; to a middle-class citizen it may be establishment or restoration of representative government as opposed to a dictatorship.

Whether real or artificial, whether inspired by political ideology or by nationalism or by a genuine desire for a better life, this cause is fundamental in motivating people to armed action. Mao Zedong leaves no doubt of its importance:

Mao Zedong and the role of politics

> Without a political goal, guerrilla warfare must fail, as it must if its political objectives do not coincide with the aspirations of the people and their sympathy, cooperation, and assistance cannot be gained.

Popular support. Revolutionary writings constantly stress the guerrillas' affiliation with the people. Guerrillas spring from the people, who in turn support their spawn, not only by furnishing their sons and daughters to the cause but also by furnishing money, food, shelter, refuge, transport, medical aid, and intelligence—support that must simultaneously be denied to the enemy. Although T.E. Lawrence called for no more than "a friendly population, not actively friendly, but sympathetic to the point of not betraying rebel movements to the enemy," he also wrote that his guerrillas "had won a province when the civilians in it had been taught to die for the ideal of freedom." Georgios Grivas, the Greek soldier who led the Cypriot rebellion in the 1950s, wrote that a guerrilla war stands no chance of success unless it has "the complete and unreserved support of the majority of the country's inhabitants." Mao stressed the importance of proper troop behaviour: the Chinese guerrilla was required to pay a peasant for food, to respect his property, and not to offend propriety by undressing in front of a peasant woman.

Essential to maintaining popular support is intelligent propaganda to advertise success and stifle news of failure. The Yugoslav Partisan leader Josip Broz Tito spread the word by newspaper, the Algerians by newspaper and radio, thereby enforcing Lawrence's dictum that the press is the greatest weapon in the army of a modern commander. The printed word has since been supplemented by the television camera and the Internet.

Leaders and recruits. Outstanding leadership is necessary at all levels if a guerrilla force is to survive and prosper. A leader must not only be endowed with intelligence and courage but must be buttressed by an almost fanatical belief in himself and his cause. T.E. Lawrence, V.I. Lenin, Leon Trotsky, Mao, Tito, the Filipino Luis Taruc, Menachem Begin, the Kenyan Jomo Kenyatta, Fidel Castro, the Algerian Ahmed Ben Bella, Ho Chi Minh, Vo Nguyen Giap—these and dozens of their lieutenants were all unusual persons, generally with civilian backgrounds. But each attracted followers to a cause, organized them, and instilled a disciplined zeal.

The guerrilla recruit must be resourceful and enduring, committed totally to the cause, if he is to withstand the hardships and dangers of guerrilla fighting. However, a prolonged and difficult campaign may force guerrilla leaders to abandon selectivity and resort to terrorist tactics in order to gain recruits—as was the case in Vietnam, where rigorous political indoctrination only partially compensated for lack of voluntary zeal.

Organization and unity of command. Protracted revolutionary warfare demands a complicated organization on both the political and military levels. Mao early developed a clandestine political-military hierarchy that began with the cadre or cellular party structure at the hamlet–village level and proceeded to the top via district, province, and regional command structures. This was roughly the concept followed by guerrilla forces in Malaya and Indochina. Tito was careful to build a parallel political organization in areas that came under his control as a foundation for his future government. Other guerrilla leaders formed civil organizations to provide money, supplies, intelligence, and propaganda. Some even established provisional governments in order to win external recognition, including representation at the United Nations.

Parallel political and military structures

Divided commands have plagued guerrilla leaders through the centuries and are probably more responsible for failed insurgencies than any other factor. The Algerian rebellion suffered severely until the National Liberation

Front absorbed or neutralized rival guerrilla groups, but it never did settle feuds between the Arabs and the Berbers or between its own internal and external commands. Internal guerrilla rivalries dangerously weakened the postcolonial governments in Mozambique and Angola, and coordination among guerrilla groups in Afghanistan dissolved after the fall of the communist regime in 1992.

The tactical organization of guerrilla units varies according to size and operational demands. Mao called for a guerrilla squad of nine to 11; his basic unit was the company, about 120 strong. Grivas initially employed sabotage–terrorist teams of four or five members. The Greek insurgency opened with about 4,000 guerrillas divided into units of 150 fighters each that, as strength increased, grew to "battalions" 250 strong. Tito began his campaign against the German invaders with about 15,000 guerrillas organized into small cadres; he ended the war with some 250,000 troops organized into brigades.

Urban guerrilla units are usually small and more tightly organized, generally in a cellular structure that, from a security standpoint, has proved valid but has suffered—as in the abortive Tupamaro insurgency in Uruguay (1963–73)—from an inability to take the war to the masses.

Arms. The guerrilla by necessity fights with a wide variety of weapons, some homemade, some captured, and some supplied from outside sources. In the earlier stages of an insurgency, the weapons have historically been primitive. The Mau Mau in Kenya initially relied on knives and clubs (soon replaced by stolen British arms). French and American soldiers in Vietnam often encountered homemade rifles, hand grenades, bombs, booby traps, mines, and trails studded with *punji* stakes (concealed sharp bamboo stakes soaked in urine to ensure infection when stepped upon). Nearly every guerrilla campaign has relied on improvisation, both from necessity and to avoid a cumbersome logistic network. Molotov cocktails and *plastique* (plastic explosive) bombs are cheap but can be extremely effective. Stolen and captured arms are also a favourite source of supply, not least because army and police depots also stock ammunition to fit the weapons.

During the Cold War both superpowers provided arms to client groups or states, even sophisticated weapons such as antitank and antiaircraft missiles. Soon after the collapse of the Soviet Union, however, the world was awash with weapons as that country's successor states and former clients emptied their arsenals. Since the early 1990s guerrilla and terrorist groups, even small and poorly funded ones, have had easy access to effective and highly destructive weapons, mostly of Soviet design.

Fighting on familar ground

Terrain and sanctuary. It was axiomatic to Mao and his followers that revolution begins in familiar terrain. Once sufficient base and operational areas are established, guerrilla operations can be extended to include cities and vulnerable lines of communication. This rural strategy may be influenced by such factors as political goal, geography, and insurgent and government strengths.

If a guerrilla force is to survive, let alone prosper, it must control safe areas to which it can retire for recuperation and repair of arms, clothing, and equipment and where recruits can be indoctrinated, trained, and equipped. Such areas are traditionally located in remote, rugged terrain, usually mountains, forests, and jungles.

Sympathetic neighbouring countries may also provide sanctuary. Ho Chi Minh's guerrillas, in the later stages of the war against France, relied on China for refuge, training, and supply of arms and equipment; in the war against the United States they used Laos and Cambodia for sanctuary. Later Thai guerrillas found sanctuary and support in Cambodia, as did Nicaraguan guerrillas in Honduras. For years Basque guerrillas from Spain found sanctuary in France, as Northern Irish guerrillas did in the Irish republic.

The local people offer a final form of sanctuary, one especially important to an urban guerrilla employing terrorist tactics. During the Cypriot war Grivas was surrounded by a British force for nearly two months without being captured. An Algerian rebel leader installed himself within 200 yards of the army commandant's office in Algiers. The position of neither rebel leader was betrayed despite generous inducements offered to collaborators.

Terror. Euphemistically termed "armed propaganda," terror is one of the most hideous characteristics of guerrilla warfare. It is used for several reasons: to focus world attention on the rebel cause with the hope of winning international support; to eliminate opposition leaders and, in the countryside, officials loyal to the government; to paralyze normal governmental activities; to intimidate them by denying them to the government); to keep one's own followers from defecting; and to raise funds by collecting ransoms for kidnapped victims.

The uses of terror

Not all guerrilla leaders have favoured the use of terrorist tactics. In Palestine the Haganah broke with the Irgun and Stern gangs over the issue. IRA leaders in Ireland also disagreed on the use of terror, which resulted in a movement divided between "official" and "provisional" wings. After decades of denying the use of terror, the leader of the Palestine Liberation Organization, Yāsir 'Arafāt, denounced the use of terrorism.

It is difficult to assess the psychological impact of terrorist tactics on the general population, but it seems that even those persons originally sympathetic to a guerrilla cause may be alienated by the indiscriminate use of terrorism, such as planting bombs in shopping centres or blowing commercial aircraft out of the sky. They also may be disillusioned when orthodox forces reply in kind, so that the population is subject to terror from both sides.

STRATEGY AND TACTICS

The broad strategy underlying successful guerrilla warfare is that of protracted harassment accomplished by extremely subtle, flexible tactics designed to wear down the enemy. The time gained is necessary either to develop sufficient military strength to defeat the enemy in orthodox battle (as did Mao Zedong in China and Ho Chi Minh in Vietnam) or to subject them to internal and external military and political pressures sufficient to cause them to seek peace favourable to the guerrillas (as the Algerian guerrillas did to France and the Angolan and Mozambican guerrillas to Portugal). This strategy embodies political, social, economic, and psychological factors to which the military element is often subordinated—without, however, lessening the ultimate importance of the military role.

That role greatly varies, as does the way it is carried out. T.E. Lawrence's Arabian campaign (1916–18) was strategically vital in protecting the British general Edmund Allenby's flank during his orthodox advance in Palestine, yet its success hinged on carrying out the Arabs' political aim, which was to expel the Ottoman Turks from tribal lands. Lawrence's acceptance of this goal, combined with his linguistic ability, imagination, perception, and immense energy, helped him to establish and maintain unity of command. Popular support was ensured in part by tribal loyalties and hatred of the Ottomans, in part by effective propaganda and decent treatment of the people. There were too many Ottomans to risk doing battle, but in any case killing the enemy was secondary to killing his line of communication. In Lawrence's words, "the death of a Turkish bridge or rail" was more important than attacking a well-defended garrison. Lawrence kept discipline and organization (Arab, not Western, style) simple and effective. He drilled his men in the employment of light machine guns and in rudimentary demolitions. Camels provided transport. The terrain was desert and desert was sanctuary, and the guerrillas were "an influence, a thing invulnerable, intangible, without front or back, drifting about like a gas." Demanding "perfect intelligence, so that plans could be made in complete certainty," Lawrence "used the smallest force in the quickest time at the farthest place." Mobility and surprise were everything. Hit-and-run tactics on a broad front cut communication, eventually causing enemy garrisons to wither on the vine. By war's end the Arabs had gained control of some 100,000 square miles while holding 600,000 Ottoman troops in passive defense. Arabs had killed or wounded 35,000 enemy at little loss to themselves. They had protected Allenby's vital flank in Palestine and had proved the truth of Lawrence's later dictum: "Guerrilla warfare is more scientific than a bayonet charge."

The "hit-and-run" tactics of T.E. Lawrence

Mao Zedong's political goal was the communist takeover of China. Guerrilla warfare alone, he realized, could not achieve this, but in a prolonged war it was an indispensable weapon, particularly in holding off the enemy until orthodox armies could take to the field.

Mao's guerrilla campaign of over two decades stressed the flexible tactics based on surprise and deception that the ancient writer Sun-tzu had called for in *The Art of War.* Mao later wrote that "guerrilla strategy must be based primarily on alertness, mobility, and attack." He demanded tactics based on surprise and deception: "Select the tactic of seeming to come from the east and attacking from the west; avoid the solid, attack the hollow; attack, withdraw; deliver a lightning blow, seek a lightning decision." Mao instructed his subordinates to accept battle only under favourable conditions, otherwise avoid it and retreat: "We must observe the principle, 'To gain territory is no cause for joy, and to lose territory is no cause for sorrow.'" Careful planning was vital: "Those who fight without method do not understand the nature of guerrilla action."

Ho Chi Minh and his able military commander Vo Nguyen Giap were disciples of Mao's teachings, as was shown in their remarkably successful campaigns against the French and, later, against the U.S. and South Vietnamese armies. Ho and Giap did not, however, hesitate to extend guerrilla operations to the cities when occasion warranted. Vietnamese organization and leadership were generally effective, albeit bloody. The use of terrain was often masterful, both tactically and for sanctuary. When popular support lagged, terrorist tactics were used, particularly the murder of pro-government village headmen, to coerce peasants into furnishing recruits, food, and information while denying these to the enemy. Operations were carefully planned and audaciously executed. As cruel as it was, the guerrilla portion of the Indochina wars must rank as one of the most successful in history.

<div style="float:left">The cost of abandoning guerrilla principles</div>

The leader who does not respect the principles of guerrilla warfare soon finds himself in trouble, particularly against effective counterguerrilla forces. Greek communist guerrillas lost their war (1946–49) for a variety of reasons, not so much because Tito deprived them of sanctuary in and supply from Yugoslavia but more because they forfeited popular support in northern Greece by their barbarous treatment of civilian hostages, by their rapacious behaviour in villages, and by kidnapping children and sending them to be raised in communist countries.

Filipino, Malayan, and Indonesian guerrillas of the 1940s and '50s suffered from poor organization and leadership as well as from lack of external support, and later movements failed for similar reasons. Uruguayan and Guatemalan insurgents lost control over terrorist tactics and suffered heavily for it. Basque guerrillas became unpopular in Spain because of their brutal assassinations. Polisario fighters, inadequately supported by Algeria and Libya, faced continuing stalemate in their war against Morocco over Western Sahara. Angolan and Mozambican guerrillas split into several factions and became pawns of Cuba (by extension, the Soviet Union), South Africa, and the United States. The use of indiscriminate terrorist tactics by the provisional wing of the IRA brought general opprobrium on their movement, including a partial loss of what had been heavy financial support from previously sympathetic Irish-Americans.

COUNTERGUERRILLA WARFARE

Perhaps the most important challenge confronting the military commander in fighting guerrillas is the need to modify orthodox battlefield thinking. This was as true in ancient, medieval, and colonial times as it is today. Alexander the Great's successful campaigns resulted not only from mobile and flexible tactics but also from a shrewd political expedient of winning the loyalty of various tribes. The few Roman commanders in Spain—Tiberius Sempronius Gracchus, Cato the Elder, the Scipios, and Pompey—who introduced more mobile and flexible tactics often succeeded in defeating large guerrilla forces, and their victories were then exploited by decent treatment of the vanquished in order to gain a relatively peaceful occupation.

In their conquest of Ireland, the Normans borrowed the enemy guerrilla tactics of feigned retreat, flanking attack by cavalry, and surprise. (These tactics were countered by the Irish retreat to impenetrable bog country.) Early settlers in Virginia and New England tried to adopt the best features of American Indian guerrilla tactics: small-unit operations, loose formations, informal dress, swift movement, fire discipline, terror, ambush, and surprise attack. As frontiers expanded, colonists reverted to European methods of formal warfare with disastrous results until a Swiss mercenary, Henry Bouquet, trained his new light-infantry regiment to fight Indian-style in the French and Indian War (1754–63). British generals fighting in the New World never quite understood Bouquet's teachings and suffered accordingly. A similar blindness cost Napoleon and his generals disastrous defeats in Spain and Russia.

<div style="float:right">Fighting guerrillas with guerrilla tactics</div>

The French conquest of Algeria (1830–44) might well have failed had it not been for tribal discord and the tactical innovations of Thomas-Robert Bugeaud, who understood the value of the ruse, the raid, and the ambush. Bugeaud dispensed with heavy columns in favour of small, fast-moving task forces, or "flying columns," which pursued and brought the Berbers to battles that were usually won by disciplined troops using superior arms. Although Bugeaud believed in constructive occupation—"the sword only prepared the way for the plough"—he nonetheless depended more on fear than on persuasion, relying on the *razzia* (raid) to implement a scorched-earth policy to starve the natives into submission. Bugeaud's offensive tactics of clearing, holding, and expanding became the model for subsequent pacification campaigns around the globe, including the United States' winning of the West and its forays into colonialism in Cuba and the Philippines.

Such were the string of colonial successes that occasional reverses due to inept leadership and ill-trained troops were shrugged off. Orthodox commanders were generally content to put faith in sheer military weight with little consideration given to the poor organization and leadership of native forces or to the lack of modern arms and allies. Blockhouses and garrisons kept the peace in pacified areas. If natives rebelled, they were put down with force.

This simplistic concept was challenged by a French general, Louis-Hubert-Gonsalve Lyautey. He had been taught by Joseph-Simon Gallieni in Indochina in 1895 that military success, in Gallieni's words, meant

nothing unless combined with a simultaneous work of organization—roads, telegraphs, markets, crops—so that with the pacification there flowed forward, like a pool of oil, a great belt of civilization.

Lyautey later employed this *tache d'huile,* or oil-spot, strategy in Algeria, where he used the army not as an instrument of repression but, in conjunction with civil services, as a positive social force—"the organization on the march." Lyautey's success went generally unheeded, as did the potency of the guerrilla weapon in World War I and subsequent decades. Native rebellions continued to be put down with force, no one paid much attention to Mao Zedong's guerrilla war, nor were orthodox commanders in the Western world greatly impressed with the guerrilla weapon in World War II.

<div style="float:right">The cost of fighting guerrillas with conventional tactics</div>

The greater the postwar shock, then, when these commanders and their subordinates were called upon to quell organized insurgencies by ideologically motivated, combat-trained guerrillas equipped with modern weapons and often politically allied with and, on occasion, supplied by the Soviet Union and its satellite countries.

Most governments and commanders simply floundered while calling for more soldiers and more weapons. The Greek army originally tried to suppress what they termed "bandits" by static defense tactics that soon failed. Once the army had received massive reinforcements of U.S. arms and equipment, it launched large-scale offensives, or "search-and-clear" operations, which met with only limited success. Chinese Nationalist commanders moved vast armies hither and yon in futile efforts to capture Mao's guerrillas before finally holing up in towns and cities, where they eventually fell prey to Mao's own army divisions. During the Hukbalahap Rebellion (1946–54), U.S.

Army advisers in the Philippines trained and equipped splendid Filipino combat teams supported by armour, aircraft, artillery, and even dogs. Large-scale search-and-destroy operations—the "ring of steel" tactic similar to that unsuccessfully employed by German commanders against Tito's guerrillas—produced minimal results, as did free-fire areas (zones in which troops may fire at anything and everything), massive and sometimes brutal interrogations of villagers, and the employment of terrorist tactics, all of which further alienated the rural people whose support was necessary to defeat the guerrillas. Wiser commanders replaced conventional tactics with small-unit patrols and a variety of ruses that largely neutralized overt guerrilla action, then turned the army to the vital task of winning civil cooperation. With this the Huk insurgency died, but by the 1970s the failure to carry out promised reforms, mainly land distribution, had brought on a guerrilla insurgency by the New People's Army that lasted into the 21st century.

British commanders in Malaya also performed ineffectually in the early phases of the communist insurgency that began in 1948. Eventually, however, they realized that the support of the rural natives was vital to their goal of eliminating the entire guerrilla apparatus. Once they had achieved a reasonable civil-military chain of command, their first priority became the reestablishment of law and order, which meant revitalizing the rural police function. The military effort concentrated on breaking up and dispersing large guerrilla formations, then depriving them of the initiative by small-unit tactics, mainly frequent patrols and ambushes based on valid intelligence often gained from natives. The subsequent civil effort was designed to win the "hearts and minds" of the people, first by providing security in the form of village police and local militias working with government forces, second by providing social reforms (land reform, schools, hospitals) that identified the government with the people's best interests. Harsh measures were necessary: compulsory census, an identity-card system, suspension of habeas corpus, search of private property without a warrant, the death sentence for persons caught with unauthorized weapons, harsh sentences for collaborators, curfews, resettlement of entire villages, and other extraordinary measures. These were somewhat palliated by the British government's promise of eventual independence and by the general unpopularity of the guerrillas among the majority Malay population as well as the urban Chinese business community.

Despite the lessons of history, including those learned in Malaya and the Philippines, orthodox commanders have continued to employ a wide range of weapons and tactics that, judged by results, have been more appropriate to conventional warfare. These have included wholesale bombings and mass artillery interdictions of suspected sanctuary areas, division- and corps-strength "sweeping" operations (in which only a few guerrillas are captured or killed while entire villages are destroyed), free-fire areas, the building of defended but isolated chains of military outposts, the construction of massive walls that can be outflanked, mass arrests, and brutal interrogations. The result: an expenditure in lives and money that in time have lost whatever support the government enjoyed at home. France backed down in Algeria, Portugal in Mozambique and Angola, the United States in Vietnam, the Soviet Union in Afghanistan. These campaigns failed because commanders chose quantity over quality to fight "little wars," in which victory is attainable only by patient application of intelligent, skillful, and extremely subtle strategy and tactics.

Precisely the same command qualities are necessary in fighting urban guerrilla warfare and international terrorism. Although a number of Western countries have established special antiterrorist military units, which at times have functioned effectively, the problem in the long run can be solved only by competent police work and by governments that refuse to allow the payment of ransoms (no matter the human cost) and refuse to be intimidated by terrorist threats into denying extradition of captured terrorists to other countries. Also necessary to put an end to terrorist depredations is a sharing of resources and intelligence among nations.   (R.B.A.)

Winning "the hearts and minds" of the people

BIBLIOGRAPHY

Theory of war.   CARL VON CLAUSEWITZ, *On War*, 3 vol. in 1 (1873; originally published in German, 3 vol., 1832–34), remains a classic and is available in many later editions both in the original and in English translation, of which the one edited by and with commentary by MICHAEL HOWARD and PETER PARET (1991) can be recommended. Other outstanding classical philosophical treatments are IMMANUEL KANT, *Perpetual Peace: A Philosophical Essay* (1903, reissued 1972; originally published in German, 1795), also available in later editions, some entitled *Eternal Peace;* JOHN STUART MILL, *On Liberty* (1859) and *Considerations on Representative Government* (1861), both available in the selection published as *Political Writings* (1981), in "The Great Books of the Western World" series; and JEAN-JACQUES ROUSSEAU, *A Lasting Peace Through the Federation of Europe, and The State of War*, trans. from French (1917).

Explanations of war as a product of imperialism are found in J.A. HOBSON, *Imperialism*, 3rd rev. ed. (1938, reprinted 1988); and in Marxist writings. Psychological theories of war are best expressed in SIGMUND FREUD, *Civilization, War, and Death*, new ed., ed. by JOHN RICKMAN (1953, reprinted 1968); and ethological theories are examined in ROBERT ARDREY, *The Territorial Imperative* (1966, reissued 1997); and KONRAD LORENZ, *On Aggression,* 2nd ed. (2002; originally published in German, 1963). NORMAN ANGELL, *The Great Illusion: A Study of the Relation of Military Power in Nations to Their Economic and Social Advantage* (1910), is an early economic study, available in many later editions. REINHOLD NIEBUHR, *Moral Man and Immoral Society* (1932, reprinted 2001), analyzes war from the ethical point of view.

A comprehensive modern analysis is QUINCY WRIGHT, *A Study of War*, 2nd ed. (1964, reprinted 1984). Other major contemporary general analyses are RAYMOND ARON, *The Century of Total War* (1954, reprinted 1985); KENNETH N. WALTZ, *Man, the State, and War* (1959, reprinted 2001); and HANS J. MORGENTHAU and KENNETH W. THOMPSON, *Politics Among Nations*, 6th ed. (1985). On nuclear war, see HERMAN KAHN, *On Escalation: Metaphors and Scenarios* (1965, reprinted 1986). INIS L. CLAUDE, JR., *Swords into Plowshares*, 4th ed. (1971, reprinted 1984), discusses United Nations approaches to peace. Later studies include EVAN LUARD, *War in International Society: A Study in International Sociology* (1986), a broad and systematic view of war in history; J. DAVID SINGER et al., *Explaining War: Selected Papers from the Correlates of War Project* (1979, reprinted 1991); and MELVIN SMALL and J. DAVID SINGER, *Resort to Arms: International and Civil Wars, 1816–1980*, rev. ed. (1982).   (J.Fr.)

Law of war.   Among comprehensive works of reference quality are L. OPPENHEIM, *International Law, a Treatise*, 8th ed., ed. by H. LAUTERPACHT, vol. 2, *Disputes, War, and Neutrality* (1962); and GEORG SCHWARZENBERGER, *International Law as Applied by International Courts and Tribunals*, vol. 2, *The Law of Armed Conflict* (1968), an interpretation of the law chiefly through court decisions.

For the history of the laws of war, see GEOFFREY BEST, *Humanity in Warfare* (1980). For the development of the law of war as it exists today, see JEAN S. PICTET (ed.), *The Geneva Conventions of 12 August 1949: Commentary*, 4 vol. (1952–60); CLAUDE PILLOUD et al. (eds.), *Commentary on the Additional Protocols of 8 June 1977 to the Geneva Conventions of 12 August 1949* (1987; originally published in French, 1986); G.I.A.D. DRAPER, *The Red Cross Conventions* (1958); WALDEMAR A. SOLF and J. ASHLEY ROACH (eds.), *Index of International Humanitarian Law* (1987); and L.C. GREEN, *Essays on the Modern Law of War*, 2nd ed. (1999).

Special treatments of developments brought about by particular military campaigns include ROBERT R. BOWIE, *Suez 1956* (1974); GEORGES ABI-SAAB, *The United Nations Operation in the Congo, 1960–1964* (1978); ABRAM CHAYES, *The Cuban Missile Crisis* (1974, reprinted 1987); RICHARD A. FALK (ed.), *The Vietnam War and International Law*, 4 vol. (1968–76); ALLAN GERSON, *Israel, the West Bank, and International Law* (1978); ALBERTO R. COLL and ANTHONY C. AREND (eds.), *The Falklands War: Lessons for Strategy, Diplomacy, and International Law* (1985); and SCOTT DAVIDSON, *Grenada: A Study in Politics and the Limits of International Law* (1987). For internal conflicts, see RICHARD A. FALK (ed.), *The International Law of Civil War* (1971, reprinted 1980); and HEATHER A. WILSON, *International Law and the Use of Force by National Liberation Movements* (1988, reprinted 1990).

Laws on particular weapons, means of conflict, and areas of war are explored in HOWARD S. LEVIE, *The Code of International Armed Conflict*, 2 vol. (1986); MORRIS GREENSPAN, *The Modern Law of Land Warfare* (1959); D.P. O'CONNELL, *The International Law of the Sea*, 2 vol. (1982–84); ANN VAN WYNEN THOMAS and A.J. THOMAS, JR., *Development of International Legal Limitations on the Use of Chemical and Biological Weapons*, 2 vol. (1968); and PETER ROWE, *Defence: The Legal Implications: Military Law and the Laws of War* (1987).

War crimes as a branch of military law are analyzed in

ROBERT K. WOETZEL, *The Nuremberg Trials in International Law: With a Postlude on the Eichmann Case* (1962); ANN TUSA and JOHN TUSA, *The Nuremberg Trial* (1983); PHILIP R. PICCIGALLO, *The Japanese on Trial: Allied War Crimes Operations in the East, 1945–1951* (1979); L.C. GREEN, *Superior Orders in National and International Law* (1976); and YORAM DINSTEIN, *The Defence of "Obedience to Superior Orders" in International Law* (1965).   (P.J.R.)

Military law. Development of military law in the United States is traced in UNITED STATES. ARMY. JUDGE ADVOCATE GENERAL'S CORPS, *The Army Lawyer: A History of the Judge Advocate General's Corps, 1775–1975* (1975); and *Military Law Review Bicentennial Issue* (1975), an anthology of articles by 17 authors. Both are useful for the general reader as well as the specialist. A concise history of British military law is found in Peter Rowe's work cited above. FREDERICK B. WIENER, *Civilians Under Military Justice: The British Practice Since 1689, Especially in North America* (1967), offers a general history of the subject, with a focus on the British administration of 18th-century America. A special aspect of military law is treated in NICO KEIJZER, *Military Obedience* (1978). INTERNATIONAL SOCIETY FOR MILITARY LAW AND THE LAW OF WAR, *The Present Evolution of Military Justice*, 2 vol. (1981), studies systems of military law throughout the world on the basis of national reports from 25 countries. See also JAMES STUART-SMITH, "Military Law: Its History, Administration, and Practice," *Law Quarterly Review*, 85:478–504 (October 1969). Journals cited in the previous section also contain many articles on the military law of many countries.   (J.S.-Sm.)

Defense economics. GAVIN KENNEDY, *Defence Economics* (1983), is a general survey written for the nonspecialist and providing information on a broad spectrum of questions of military appropriations and expenditures. Historical studies include J.M. WINTER (ed.), *War and Economic Development* (1975), addressing the economic consequences of war on the preindustrial economies of Europe; GAUTAM SEN, *The Military Origins of Industrialization and International Trade Rivalry* (1983), exploring the influence of military technology on the industrial development of Europe; and EMILE BENOIT, *Defense and Economic Growth in Developing Countries* (1973), challenging the assumption that defense spending is incompatible with economic growth and attempting to show that defense spending has actually assisted economic development in some Third World countries. SAADET DEGER and ROBERT WEST (eds.), *Defence, Security, and Development* (1987), is a collection of articles by scholars from several countries who criticize Benoit's method and conclusions and provide a more complex assessment of the connection between economic growth and national security. A detailed study of governmental defense planning in poorer economies is presented in STEPHANIE G. NEUMAN (ed.), *Defense Planning in Less-Industrialized States: The Middle East and South Asia* (1984). For a view that defense spending inhibits economic performance, based on international comparative data and statistical analysis, see ROBERT W. DEGRASSE, JR., *Military Expansion, Economic Decline: The Impact of Military Spending on U.S. Economic Performance*, expanded ed. (1983). CHRISTIAN SCHMIDT (ed.), *The Economics of Military Expenditures: Military Expenditures, Economic Growth, and Fluctuations* (1987), collects papers by most of the world's leading specialists in defense economics, providing a rich agenda in the contribution of economic analysis to defense dilemmas.

A rare comparative study of defense industries in both capitalist and communist economies of such countries as the United States, the Soviet Union, France, Germany, Sweden, Czechoslovakia, Italy, China, Israel, the United Kingdom, and some representatives of the Third World is provided in NICOLE BALL and MILTON LEITENBERG (eds.), *The Structure of the Defense Industry: An International Survey* (1983).   (G.Ke.)

Strategy. EDWARD MEAD EARLE *et al.* (eds.), *Makers of Modern Strategy: Military Thought from Machiavelli to Hitler* (1943, reprinted 1971), remains a most competent anthology on the development of the military mind and art. Its worthy successor is PETER PARET (ed.), *Makers of Modern Strategy: From Machiavelli to the Nuclear Age* (1986), which repeats three of the essays and provides more than 20 new ones.

For works that explore the complex correlation between military campaigns and such nonmilitary factors as economic, technological, and human resources, psychological conditions of people involved, and political decision making by statesmen and generals, the reader will have to turn to broad military histories, such as JAMES R.M. BUTLER (ed.), *Grand Strategy*, 6 vol. in 7 (1956–76), an analysis of the high-level conduct of war by the British High Command; GORDON WRIGHT, *The Ordeal of Total War, 1939–1945* (1968); HENRI MICHEL, *The Second World War*, 2 vol. (1975; originally published in French, 1968–69); and PETER CALVOCORESSI, GUY WINT, and JOHN PRITCHARD, *Total War: Causes and Courses of the Second World War*, 2nd rev. ed. (1989).

The role of the U.S. Army and the War Department in World War II is studied in MAURICE MATLOFF and EDWIN M. SNELL, *Strategic Planning for Coalition Warfare*, 2 vol. (1953–59, reprinted 1968); KENT ROBERTS GREENFIELD (ed.), *Command Decisions* (1960, reprinted 1984); and RONALD H. SPECTOR, *Eagle Against the Sun: The American War with Japan* (1985). Russian and Soviet strategists are discussed in JOHN ERICKSON, *Stalin's War with Germany* (1975), and *The Road to Berlin: Continuing the History of Stalin's War with Germany* (1983).   (Ma.M./M.E.Ho.)

Strategy in the nuclear age is surveyed in JOHN BAYLIS *et al.*, *Contemporary Strategy*, 2nd rev. ed., 2 vol. (1987); INSTITUTE FOR STRATEGIC STUDIES, *Problems of Modern Strategy* (1970); and LAWRENCE MARTIN (ed.), *Strategic Thought in the Nuclear Age* (1979). LAWRENCE FREEDMAN, *The Evolution of Nuclear Strategy*, 2nd ed. (1989), summarizes the history of thought on nuclear strategy. FRED KAPLAN, *The Wizards of Armageddon* (1983), is a look at the thinkers and strategists themselves.

The classics of postwar strategic thinking include BERNARD BRODIE, *Strategy in the Missile Era* (1959, reprinted 1965); HERMAN KAHN, *On Thermonuclear War*, 2nd ed. (1961, reprinted 1978), and *On Escalation: Metaphors and Scenarios* (1965, reprinted 1986); and THOMAS C. SCHELLING, *The Strategy of Conflict* (1960, reprinted 1980), and *Arms and Influence* (1966, reprinted 1976). Among later contributions, EDWARD N. LUTTWAK, *Strategy: The Logic of War and Peace* (1987), is a complex scholarly treatment of strategy as a system of thought; and MICHAEL HOWARD, *The Causes of Wars and Other Essays* (1983), is a collection of previously published works by an influential author.

The theory of deterrence is considered in PATRICK M. MORGAN, *Deterrence: A Conceptual Analysis*, 2nd ed. (1983); and carefully analyzed in ALEXANDER L. GEORGE and RICHARD SMOKE, *Deterrence in American Foreign Policy: Theory and Practice* (1974). PAUL BRACKEN, *The Command and Control of Nuclear Forces* (1983), is another authoritative treatment; and JOHN J. MEARSHEIMER, *Conventional Deterrence* (1983), applies the deterrence theory to land warfare.

Special branches of strategic thought are examined in GEOFFREY TILL, *Maritime Strategy and the Nuclear Age*, 2nd ed. (1984); and M.J. ARMITAGE and R.A. MASON, *Air Power in the Nuclear Age, 1945–84: Theory and Practice*, 2nd ed. (1985). On Soviet strategic thinking, see JOHN BAYLIS and GERALD SEGAL (eds.), *Soviet Strategy* (1981). Influence of the Vietnam experience is studied in HARRY G. SUMMERS, JR., *On Strategy: A Critical Analysis of the Vietnam War* (1982).   (L.D.Fr.)

Tactics of land warfare. For a general introduction, see MARTIN VAN CREVELD, *Technology and War: From 2000 B.C. to the Present* (1989). JOHN KEEGAN, *The Illustrated Face of Battle: A Study of Agincourt, Waterloo, and the Somme*, rev. ed. (1989), is excellent on the tactics of three critical, widely separated battles; see also ARTHER FERRILL, *The Origins of War: From the Stone Age to Alexander the Great* (1985), which covers the period indicated while arguing that tactics underwent no basic change from the earliest time to Waterloo. The best book on tribal warfare remains HARRY HOLBERT TURNEY-HIGH, *Primitive War: Its Practice and Concepts*, 2nd ed. (1971). Biblical warfare is covered in YIGAEL YADIN, *The Art of Warfare in Biblical Lands: In the Light of Archaeological Study*, 2 vol. (1963; originally published in Hebrew, 1963). On ancient warfare in general, see PETER CONNOLLY, *Greece and Rome at War* (1981); and VICTOR DAVIS HANSON, *The Western Way of War: Infantry Battle in Classical Greece* (1989). Of several excellent books on medieval warfare, J.F. VERBRUGGEN, *The Art of Warfare in Western Europe During the Middle Ages: From the Eighth Century to 1340* (1977; originally published in Dutch, 1954), is perhaps the strongest on tactics. The most expert contemporary work on early modern warfare is undoubtedly GEOFFREY PARKER, *The Military Revolution: Military Innovation and the Rise of the West, 1500–1800* (1988). The early 18th century is covered in DAVID CHANDLER, *The Art of Warfare in the Age of Marlborough* (1976), excellently researched and well written. For subsequent developments in the same century, see CHRISTOPHER DUFFY, *The Military Experience in the Age of Reason* (1988); as well as ROBERT S. QUIMBY, *The Background of Napoleonic Warfare: The Theory of Military Tactics in Eighteenth-Century France* (1957, reprinted 1968), a meticulous inquiry into tactics before and during the French Revolution. LARRY H. ADDINGTON, *The Patterns of War Since the Eighteenth Century* (1984); and HEW STRACHAN, *European Armies and the Conduct of War* (1983), are good general accounts. Two older works that can still be read with profit are THEODORE ROPP, *War in the Modern World* (1959, reprinted 1981); and J.F.C. FULLER, *The Conduct of War, 1789–1961: A Study of the Impact of the French, Industrial, and Russian Revolutions on War and Its Conduct* (1961, reprinted 1981). WILLIAM MCELWEE, *The Art of War: Waterloo to Mons* (1974), is probably the best of many works on 19th-century warfare. For the tactics of

World War I in general, see TONY ASHWORTH, *Trench Warfare, 1914–1918: The Live and Let Live System* (1980); on the offensive tactics developed by the Germans, TIMOTHY T. LUPFER, *The Dynamics of Doctrine: The Changes in German Tactical Doctrine During the First World War* (1981), is excellent. For World War II, B.H. LIDDELL HART, *History of the Second World War* (1971, reissued 1982), though flawed on some counts, remains the single most comprehensive operational history. On armoured warfare, see F.W. VON MELLENTHIN, *Panzer Battles: A Study of the Employment of Armor in the Second World War*, trans. from German (1956, reissued 1982); and CHARLES MESSENGER, *The Blitzkrieg Story* (1976); for the ways of countering it, see JOHN WEEKS, *Men Against Tanks: A History of Anti-Tank Warfare* (1975). The story of the Korean War is ably told in CALLUM A. MACDONALD, *Korea, the War Before Vietnam* (1987); that of the Arab-Israeli Wars, in TREVOR N. DUPUY, *Elusive Victory: The Arab-Israeli Wars, 1947–1974* (1978, reissued 1984). For the Vietnam War, see ANDREW F. KREPINEVICH, JR., *The Army and Vietnam* (1986). MICHAEL CARVER, *War Since 1945* (1980, reissued 1990), provides an excellent general overview. (M.v.C.)

Naval tactics. The most extensive work devoted exclusively to naval tactics is S.S. ROBISON and MARY L. ROBISON, *A History of Naval Tactics from 1530 to 1930: The Evolution of Tactical Maxims* (1942). GIUSEPPE FIORAVANZO, *A History of Naval Tactical Thought* (1979; originally published in Italian, 1973), is an authoritative later analysis. WAYNE P. HUGHES, JR., *Fleet Tactics: Theory and Practice* (1986), includes history but is more attentive to the art and science of tactics.

WILLIAM LEDYARD RODGERS, *Naval Warfare Under Oars, 4th to 16th Centuries* (1939, reprinted 1967), interprets galley warfare. The history of tactics in the age of fighting sail as presented by JULIAN S. CORBETT in his numerous works, from *Drake and the Tudor Navy: With a History of the Rise of England as a Maritime Power*, 2 vol. (1898, reissued 1988), to *England in the Mediterranean: A Study of the Rise and Influence of British Power Within the Straits, 1603–1713* (1904, reprinted 1987), remains unsurpassed. A.T. MAHAN, *The Influence of Sea Power upon History, 1660–1783* (1890), available in many later editions, is a classic naval history. Studies of tactics in the age of steam and steel include BRADLEY A. FISKE, *The Navy as a Fighting Machine*, 2nd ed. (1918, reprinted 1988); ROMEO BERNOTTI, *The Fundamentals of Naval Tactics* (1912; originally published in Italian, 1910); and W. BAINBRIDGE-HOFF, *Elementary Naval Tactics* (1894). RICHARD HOUGH, *The Great War at Sea, 1914–1918* (1983), explores the tactics of naval operations in World War I. The transition from battleship to aircraft carrier is discussed in BERNARD BRODIE, *A Layman's Guide to Naval Strategy* (1942). Studies of naval tactics in World War II are found in comprehensive histories, such as SAMUEL E. MORISON, *History of United States Naval Operations in World War II*, 15 vol. (1947–62); S.W. ROSKILL, *The War at Sea, 1939–1945*, 3 vol. in 4 (1954–61); and FRIEDRICH RUGE, *Der Seekrieg: The German Navy's Story, 1939–1945* (1957; originally published in German, 1954; also published as *Sea Warfare, 1939–1945: A German Viewpoint*). CLARK G. REYNOLDS, *The Fast Carriers: The Forging of an Air Navy* (1968, reprinted 1978), studies carrier operations. (W.P.H.)

Air tactics. CHARLES HARVARD GIBBS-SMITH, *Aviation: An Historical Survey from Its Origins to the End of World War II*, 2nd ed. (1985), and *Flight Through the Ages: A Complete, Illustrated Chronology from the Dreams of Early History to the Age of Space Exploration* (1974), provide basic introduction to the development of airplanes as a military force. ROBIN HIGHAM, *Air Power: A Concise History*, 3rd rev. ed. (1988); and BILL GUNSTON (ed.), *Aviation: The Complete Story of Man's Conquest of the Air* (1978), are general surveys. EDWARD H. SIMS, *Fighter Tactics and Strategy, 1914–1970*, 2nd ed. (1980); and ROBERT L. SHAW, *Fighter Combat: The Art and Science of Air-to-Air Warfare*, 2nd ed. (1988), focus on fighter planes. R.A. MASON (ed.), *War in the Third Dimension: Essays in Contemporary Air Power* (1986), emphasizes continuity, innovation, and convergence in development of military aeronautics. LON O. NORDEEN, *Air Warfare in the Missile Age* (1985), provides an excellent overview of air tactics from 1964 to the 1980s. (D.MacI.)

Logistics. MARTIN VAN CREVELD, *Supplying War: Logistics from Wallenstein to Patton* (1977), is an insightful ground-breaking history of logistics. Classic studies of the subject include GEORGE CYRUS THORPE, *George C. Thorpe's Pure Logistics: The Science of War Preparation*, new ed., with an introduction by STANLEY L. FALK (1986); G.C. SHAW, *Supply in Modern War* (1938), mainly on subsistence; S.L.A. MARSHALL, *The Soldier's Load and the Mobility of a Nation* (1950, reprinted 1980); and HENRY E. ECCLES, *Logistics in the National Defense* (1959, reprinted 1981), with emphasis on theory.

The 18th-century logistics systems are examined in LEE KENNETT, *The French Armies in the Seven Years' War: A Study in Military Organization and Administration* (1967, reprinted 1986); and ERNA RISCH, *Supplying Washington's Army* (1981). The U.S. Army experience is surveyed in JAMES A. HUSTON, *The Sinews of War: Army Logistics 1775–1953* (1966, reprinted 1988); EDWIN A. PRATT, *The Rise of Rail-Power in War and Conquest, 1833–1914* (1916), an old but still useful survey; ROBERT GREENHALGH ALBION and JENNIE BARNES POPE, *Sea Lanes in Wartime: The American Experience 1775–1945*, 2nd ed. (1968); and C.B.A. BEHRENS, *Merchant Shipping and the Demands of War*, rev. ed. (1978), on the overseas supply. ROLAND G. RUPPENTHAL, *Logistical Support of the Armies*, 2 vol. (1953–59, reprinted 1985–87); and RICHARD M. LEIGHTON and ROBERT W. COAKLEY, *Global Logistics and Strategy*, 2 vol. (1955–68), provide the U.S. Army's official history of logistics in World War II, in the European theatre and in the framework of coalition strategy, respectively. R. ELBERTON SMITH, *The Army and Economic Mobilization* (1959, reprinted 1985), analyzes the U.S. Army's World War II economic mobilization.

CHARLES J. HITCH and ROLAND N. MCKEAN, *The Economics of Defense in the Nuclear Age* (1960, reissued 1978), is the "bible" of the managerial reforms in the U.S. Defense Department; and NEVILLE BROWN, *Strategic Mobility* (1963), explores a facet of post-World War II international strategy and logistics. (R.M.Le.)

Intelligence. RICHARD DEACON, *Spyclopedia: The Comprehensive Handbook of Espionage* (1987), is an original reference work providing concise information on intelligence organizations of more than 30 countries within a chronology of 25 centuries of intelligence activity. JOHN RANELAGH, *The Agency: The Rise and Decline of the CIA*, rev. ed. (1987), offers a well-documented nonpartisan historical analysis of the organization and personalities; it can be complemented by JOHN PATRICK QUIRK *et al.*, *The Central Intelligence Agency: A Photographic History* (1986). JAMES BAMFORD, *The Puzzle Palace: A Report on America's Most Secret Agency* (1982), explores in a well-researched investigative framework the National Security Agency's operations, using unpublished archival and official information. A general survey is given in MARK M. LOWENTHAL, *U.S. Intelligence: Evolution and Anatomy* (1984). GERALD W. HOPPLE and BRUCE W. WATSON (eds.), *The Military Intelligence Community* (1986); and SCOTT D. BRECKINRIDGE, *The CIA and the U.S. Intelligence System* (1986), examine the organizations and operations of intelligence professionals and the relevant legal and ethical problems. Further discussion of the latter is available in BRUCE W. WATSON and PETER M. DUNN (eds.), *Military Intelligence and the Universities: A Study of an Ambivalent Relationship* (1984). Useful reference information is found in JOINT CHIEFS OF STAFF, *Department of Defense Dictionary of Military Terms* (1988); and GEORGE C. CONSTANTINIDES, *Intelligence and Espionage: An Analytical Bibliography* (1983), an annotated list of about 500 important nonfiction works on a group of related topics. (B.W.Wa.)

Guerrilla warfare. ROBERT B. ASPREY, *War in the Shadows: The Guerrilla in History*, 2 vol. (1975), surveys guerrilla and counterguerrilla warfare from its origin to the 1970s. For specific guerrilla studies, see REGINALD HARGREAVES, *Beyond the Rubicon: A History of Early Rome* (1967); FERDINAND SCHEVILL, *The History of the Balkan Peninsula, from the Earliest Times to the Present Day* (1922, reprinted 1971); R.C. FALL, *The Two Viêt-Nams: A Political and Military Analysis*, 2nd rev. ed. (1967, reprinted 1984). (R.B.A.)

Warsaw

Warsaw (Polish: Warszawa), the capital and largest city of Poland, is notable among Europe's capital cities not for its size, its age, or its beauty but for its indestructibility. It is a phoenix that has risen repeatedly from the ashes of war. Having suffered fearful damage during the Swedish and Prussian occupation of 1655–56, it was again assaulted in 1794, when the Russian army massacred the population of the right-bank suburb of Praga. In 1944, after the Warsaw Uprising failed, by Hitler's order the city was razed; the left-bank suburbs, controlled by the Germans, were emptied of their remaining population; and the buildings were systematically reduced to rubble by fire and dynamite. In 1945, however, the people of Warsaw, the Varsovians, returned, and the city resumed its role as the capital of Poland and the country's centre of social, political, economic, scientific, and cultural life. Many of the historic streets, buildings, and churches have been restored exactly according to their original forms. Since the second half of the 18th century, the emblem of Warsaw (originally a siren) has been a mermaid with sword and shield in hand, representing the creature who in legend led a prince to the site of Warsaw and ordered him to found the city. The city's motto is, appropriately, "Contemnit procellas" ("It defies the storms").

This article is divided into the following sections:

Physical and human geography

THE LANDSCAPE

The city site. Warsaw lies on the Vistula (Wisła) River, about 240 miles (386 kilometres) southeast of the Baltic coast city of Gdansk. It is situated in the middle of the Warsaw Plain, a glacier-formed basin that ranges from 250 to 380 feet (76 to 116 metres) above sea level. Divided into right- and left-bank portions by the river, the city extends about 18 miles from north to south and 16 miles from east to west. The river is some 3,900 feet (1,190 metres) wide at this point, although the riverbed has been artificially narrowed by embankment to a third of this width.

Climate. The climate is moderate and rather cool, the prevailing westerly winds bringing frequent changes of weather. The average yearly temperature is 46° F (8° C), with a July average of 66° F (19° C) and a January average of 26° F (−3° C). Yearly rainfall averages 21 inches (541 millimetres), most of which falls in the summer. Snow cover persists for 50 to 64 days a year.

The city layout. The size of Warsaw reflects the historical fortunes of the city. From about 0.5 square mile (1.25 square kilometres) in the 17th century, it expanded to 50 square miles by 1937 and, in the postwar period, to 172 square miles by 1957. Growth has continued since. The subdivision into seven districts—Śródmieście (the city's centre), Żoliborz, Wola, Ochota, Mokotów, Praga-Południe (Praga South), and Praga-Północ (Praga North)—reflects centuries-old local names, but Warsaw is now virtually a new creation, with a layout that only partly resembles the historic city. The changes reflect a conscious planning of social and economic functions. Industries and warehouses are located on the outskirts or between modern housing developments; park areas have tripled in size; and streets, though still largely based on the old network, have been widened. The Old and New towns, Nowy Świat Avenue, and the city churches and palaces, on the other hand, have all been carefully reconstructed.

Warsaw possesses a wide variety of architectural monuments, whether as replicas or originals. In the Old Town, the Gothic St. John's Cathedral and the red-brick fortifications known as the Barbican remain from the medieval period. The houses of the Old Town Market Square have been rebuilt in the splendour of their 15th-century style. There are many Baroque churches of the Counter-Reformation period, including the Jesuit Church next to the cathedral and the Church of the Holy Cross, which contains Chopin's heart. The magnificently reconstructed Royal Castle, decorated in late 18th-century style, is on Zamkowy Square. Other royal and aristocratic palaces are at Łazienkowski Park and at John III Sobieski's Wilanów. Remnants of the tsarist era are evident in the Church of St. Alexander in the middle of Trzech Krzyży Square and in the vast Alexander Citadel on the riverside, north of the New Town. The grandest of tsarist monuments, the colossal Orthodox Cathedral (1911), was demolished by the Polish government in the 1920s, but its symbolic role in the city has been assumed by the massive Palace of Culture and Science (1949), built by the Soviets south of the Old Town. The city's modern architecture is generally regarded as undistinguished. Although the prewar garden suburbs of Żoliborz and Saska Kępa have survived, the vast sprawl of contemporary suburbia is made up in large part of seemingly endless expanses of uniform, prefabricated concrete apartment blocks.

Numerous historical monuments adorn Warsaw, some of which have been the object of political conflict. The postwar government was sensitive toward monuments and tended to discourage unapproved representations of people and events. For instance, the national shrine of the Tomb of the Unknown Soldier, which contains the body of a Polish youth killed in the battle for Lwów in 1919, bears only inscriptions starting with the Spanish Civil War in 1937. There is an imposing monument unveiled in 1948 in the Muranów area honouring the Heroes of the Ghetto Rising (1943), but not until 1989, the year in which Solidarity formed the country's first noncommunist national government since World War II, was there a memorial honouring the Home Army, which fought the Germans in the 1944 Warsaw Uprising. The statue of Feliks Dzerzhinsky (Polish: Dzierżyński), founder of the Soviet security police, which stood on Saxon Square on the spot where Tsar Nicholas I had raised a statue to his loyalist Polish generals, was removed in 1990. Other monuments affected by politics include the Nicolaus Copernicus statue on Ulica (street) Krakowskie Przedmieście, which was the object of struggles with the Nazi occupiers, and the statue of Frédéric Chopin, in Łazienkowski Park, which was destroyed by the Nazis in 1940 but has been reconstructed.

THE PEOPLE

The multinational population of Warsaw was transformed as a result of World War II, and today the city is com-

Growth of the city

Historical monuments

posed almost entirely of Poles. For centuries, though, Warsaw had been a place where the Polish-speaking Roman Catholic majority lived alongside Jews, Germans, and Russians. Early in the 20th century the largely Yiddish-speaking Jewish community accounted for almost 50 percent of the population, although it declined somewhat after 1918. The old German community, originally connected with trade and commerce, was being assimilated, however, and the Russian community, influential in the 19th century, had dwindled. From 1939 to 1945, what remained of the former diversity was destroyed. Warsaw's Jews were virtually annihilated by the Nazis, and their few remaining numbers have continued to decrease. The intelligentsia also was decimated and the administrative class connected with the prewar republic dispersed and the working class diminished by deaths and deportations. After the war Warsaw had to be completely repopulated by returning refugees, by a vast influx of peasants from the countryside, and by the families of officials connected with the new communist state. The overwhelming majority of the people are Roman Catholic.

THE ECONOMY

Industry and commerce. After 1948, when Poland's communist government was established, the largest segment of the city's labour force was employed by state-owned and cooperatively owned sectors of the national economy; manufacturing accounted for about one-third

Scarcity of consumer goods

of the workers in the 1980s. Shortages of some consumer goods and food items were a problem, symbolized by the rather common sight of people standing in lines to buy goods. Electrical engineering, metallurgy (including the Warsaw steelworks), machine production (including automobile manufacturing), and toolmaking, chemical, printing, textile and clothing, and food enterprises dominate the economy. The Warsaw region is important to Poland agriculturally, for it constitutes a highly specialized gardening and vegetable centre.

Transportation. Warsaw is the hub of main rail, road, and air routes that are of importance to eastern Europe. Expressways have been built through the city along both banks of the Vistula and in the form of a ring road through the inner suburbs. Motor traffic, however, is light in comparison with that of western European cities, and it still shares the capital's main streets with a surface tramway system. The Okęcie airport, with two terminals, international and domestic, is in the Ochota district to the south.

ADMINISTRATION AND SOCIAL CONDITIONS

Government. As the capital of the Republic of Poland, Warsaw houses all the central institutions of the national government. The Sejm, Poland's national legislature, is not far from the crossroads of Nowy Świat and Aleje Jerozolimskie. South of Łazienkowski Park is Belweder (Belvedere) Palace, the office of the president of the national government. The government of Warsaw is run by an elected City Council, headed by a city president. Warsaw's seven subdivisions also have their own elected legislatures. Until 1990 the city administration was only nominally elective and subject to the Warsaw Committee of the Polish United Workers' Party, the country's communist party. The city is also the administrative centre of the Warsaw Capital Province (Województwo Stołeczne Warszawskie).

Services and health. Like most large cities, Warsaw is continually expanding its infrastructure to keep pace with its growth. A postwar housing shortage was alleviated with prefabricated housing units, and housing construction in the suburbs and future planning have continued. As in many European countries, medical and health services are virtually free for all citizens. Hospitals, outpatient clinics, and medical research facilities are widespread.

Education. Education in Warsaw benefits from the presence of the headquarters of the Polish Academy of Sciences, which coordinates research in both physical and social sciences through a number of institutes and industrial establishments. The Technical University of Warsaw and the University of Warsaw are notable institutions. Major libraries include the library (established in 1817)

of the University of Warsaw and the National Library (1919); there are also a number of specialist libraries.

CULTURAL LIFE

Warsaw's writers, artists, and musicians play a major role in creating the cultural values of the nation. The majority of the members of such bodies as the Polish Union of Writers and the Polish Union of Composers work in the city, which is also the seat of such prominent institutions as the National Museum and the Zachęta Art Gallery. Poland's leading theatre and radio and television operations are centred in Warsaw. The National Philharmonic orchestra draws large crowds. There are numerous specialist museums, and, among the many social, cultural, and educational associations, the Friends of History in Warsaw and the Chopin societies are prominent.

A centre of Polish culture

Extensive recreational facilities exist in and around the city. Several large and many smaller parks provide open space to accommodate a variety of outdoor activities. Indoor and outdoor swimming pools, sport and physical culture centres, and ice rinks are prevalent. Major sporting and other events take place in a number of stadiums, the largest being the 100,000-capacity Tenth Anniversary Stadium, built to commemorate a decade of reconstruction following World War II.   (Ja.D./A.H.D./N.D./Ed.)

History

FOUNDATION AND EARLY DEVELOPMENT

The origins of Warsaw remain obscure. Excavations within present urban limits have confirmed the existence of Stare Bródno, a small trading settlement of the 10th and early 11th centuries AD. Its functions were taken over successively by Kamion (*c.* 1065) and Jazdow (first recorded in 1262). About the end of the 13th century, Jazdow was moved about two miles to the north, to a village named Warszowa (Warsaw), and the community was strengthened by the protection of a castle. From 1339, authority was invested in a bailiff and, from 1376, in a city council. By the end of the 14th century, the growing settlement had a double line of protective ramparts.

In the 15th century the town became the capital of the duchy of Mazovia, and the New Town sprang up to the north of the original, constricted site, afterward known as the Old Town. In 1526 both city and province became incorporated into the kingdom of Poland; from 1569 the Sejm met in Warsaw, and from 1573 the elections of the kings took place there. The first permanent bridge was built across the Vistula in 1573, and in 1596 King Sigismund III Vasa began to remodel the castle as a royal residence. In 1611 the king and his court finally moved from Kraków (Cracow) to Warsaw, making it the capital of the Polish state. Powerful persons built residences in Warsaw, and autonomous settlements sprang up around its periphery. This growth proved short-lived, for a Swedish invasion (1655–56) devastated the flourishing city. Afterward the War of the Polish Succession (1733–38) brought economic decay and pestilence.

The Old and New towns

GROWTH OF THE MODERN CITY

The 18th century. The development of manufacturing, banks, and other enterprises during the early 18th century provided a firm economic base for a number of early exercises in urban planning. During the reign (1764–95) of King Stanisław II August Poniatowski, Warsaw became the centre of the Polish Enlightenment. The first lay school (Szkoła Rycerska) was opened in 1765, and in 1773 the Committee on National Education began its activity in the city. The Polish theatre and numerous printing establishments also flourished. Warsaw played an important role in the striving for Polish political rebirth (following the first partition of Poland by Austria, Prussia, and Russia in 1772) when a parliamentary constitution was proclaimed in the city on May 3, 1791. The national insurrection of 1794, led by Tadeusz Kościuszko against the Russo-Prussian second partition, was brutally crushed; the ensuing third partition of Poland among Russia, Prussia, and Austria left Warsaw a provincial town of South Prussia.

Warsaw by the French Army in 1806 was followed a year later by Napoleon's creation of the duchy of Warsaw, a measure that reinstated the city as a capital. The emperor's downfall, however, led to occupation by Russia.

Under the Congress Kingdom of Poland (1815–30), formed by the Congress of Vienna and ruled by the Russian tsar, real national independence remained an elusive goal, and Warsaw figured prominently in struggles to throw off foreign domination. The Russo-Polish War of 1831, in which the Poles held the initial advantage, ended with the storming of Warsaw's defenses and the initiation of 30 years of military rule. Economic growth, however, continued, and by the mid-19th century textile, metal, and tannery industries were well established and the city had become the centre of a continentwide rail network. A fresh cycle of insurrection, which broke out in January 1863, led to the brief existence of an underground National Government in Warsaw. The suppression of the revolt led in 1864 to the abolition of the Congress Kingdom. Warsaw became a provincial city of the Russian Empire's "Vistula Land." A period of Russification was launched, and Varsovians abandoned national politics for a period of "positivism," which aimed to preserve Polish culture at all costs. Population soared, reaching 756,000 by 1903, and urban services underwent extensive modification. Despite revolutionary activity between 1905 and 1907, censorship was alleviated, Polish schools and other cultural institutions were established, and Warsaw experienced a cultural renaissance. After World War I the city regained its status as the national capital.

World War II and contemporary Warsaw. The population of Warsaw passed the 1,000,000 mark in 1925. The period between the world wars was marked by further advances despite a period of inflation, depressions and slumps in trade, and political instability. Automobile and aircraft manufacture were introduced; city services underwent further expansion, and Warsaw's emergence as a European cultural centre was symbolized by the beginning of such international competitions as the International Chopin Competition for Pianists (1927) and the Henryk Wieniawski International Violin Competition (1935).

During the Nazi siege of Warsaw in 1939, more than 10,000 citizens perished and more than 50,000 were wounded before the lack of supplies forced a surrender. The subsequent Nazi occupation was aimed at reducing Warsaw to a provincial city; its cultural treasures were systematically plundered and its inhabitants carried away to German labour camps or to concentration camps.

Warsaw's Jewish community was devastated. At the turn of the century the city had contained the largest urban concentration of Jews in the world. Warsaw's Jews were heavily represented in the city's bourgeoisie and intelligentsia, especially in the commercial classes and the professions. In addition to full religious and political freedom, Warsaw's Jewry enjoyed its own press, its own Yiddish theatre, and its own Jewish schools. Conflict with the rest of Warsaw society existed, but it was not alarming until immediately before the war.

Following German entry into Warsaw, a Jewish ghetto was established, surrounded by a high wall. Disease, starvation, and overcrowding caused thousands to perish before deportations to the Nazi death camps, especially to Treblinka, began in late 1941. Some 312,000 Jews were sent to the gas chambers in 1942 alone. The Warsaw Ghetto Uprising of April 1943, in which more than 60,000 Jews died, signaled a last, heroic act of defiance in the face of impending annihilation. The demolition by the Nazis of the Great Synagogue (now restored) near Aleja (avenue) General Karol Świerczewskiego symbolized the end of six centuries of Jewish Warsaw.

Near the war's end Warsaw became the national resistance centre. With the Soviet forces nearing the city, the Warsaw Home Army rose up against the weakened German garrison and was near victory when German reinforcements arrived and wiped out the Polish resistance. From 150,000 to 180,000 of the city's people died in the Warsaw Uprising of 1944. In all, some 600,000 to 800,000 Varsovians are estimated to have died between 1939 and 1944, and the Soviet armies in 1945 found the city in a state of almost total devastation. On Feb. 1, 1945, the Polish government made Warsaw its capital, and an office for urban reconstruction was set up. In the decades that followed the city was rebuilt; the scars of war almost entirely healed over, and the city expanded beyond its prewar size in both area and population.   (Ja.D./A.H.D./N.D.)

With the demise of the communist government in Poland in 1989, Warsaw underwent a rapid transition from command to market economy. Closed since World War II, the Warsaw Stock Exchange reopened and became an important market in central Europe. Throughout the 1990s, Warsaw enjoyed an economic and construction boom, which dramatically reduced unemployment and transformed the city's skyline with new office towers and hotels.   (Ed.)

BIBLIOGRAPHY. The first three published volumes of the Polish-language series *Dzieje Warszawy*, a comprehensive survey of Warsaw published by the Polish Academy of Sciences, are MARIA BOGUCKA *et al., Warszawa w latach 1526–1795* (1984); STEFAN KIENIEWICZ, *Warszawa w latach 1795–1914* (1976); and KRZYSZTOF DUNIN-WĄSOWICZ, *Warszawa w latach 1939–1945* (1984). ROBERT E. DICKINSON, *The West European City,* 2nd ed. (1961), contains a description of the site and layout of the city; JAN ZACHWATOWICZ and PIOTR BIEGAŃSKI, *The Old Town of Warsaw,* trans. from the Polish (1956), is a pictorial record; A. CIBOROWSKI, *Warsaw: A City Destroyed and Rebuilt,* 2nd ed. (1969, originally published in Polish, 1964), is a history of Warsaw and includes a description of the city as it was in 1939 and the story of its destruction. OLGIERD BUDREWICZ and EDWARD FALKOWSKI, *Homo Varsoviensis (Warsaw Man),* trans. from the Polish (1970), emphasizes postwar reconstruction. EDWARD D. WYNOT, *Warsaw Between the World Wars: Profile of the Capital City in a Developing Land, 1918–1939* (1983), is a historical survey. JOANNA K.M. HANSON, *The Civilian Population and the Warsaw Uprising of 1944* (1982); JAN M. CIECHANOWSKI, *The Warsaw Rising of 1944* (1984; originally published in Polish, 1971); and ISRAEL GUTMAN, *The Jews of Warsaw, 1939–1943: Ghetto, Underground, Revolt,* trans. from the Hebrew (1982), are scholarly historical discussions. The following are pictorial works, with texts in English translation: EDMUND KUPIECKI, *Warsaw: Landscape and Architecture,* 3rd ed. (1970); JULIUSZ A. CHROSCICKI and ANDRZEJ ROTTERMUND, *Atlas of Warsaw's Architecture* (1978); and KRZYSZTOF JABLONSKI, *Warsaw, A Portrait of the City* (1979).   (Ed.)

Nationalist uprisings and industrial growth (margin note)

George Washington

General, statesman, and first president of the United States, George Washington was born in Westmoreland County, Virginia, on February 22 (February 11, old style), 1732. His father was Augustine Washington, who had gone to school in England, had tasted seafaring life, and was then managing his growing Virginia estates. His mother was Mary Ball, whom Augustine, a widower, had married early the previous year. The paternal lineage had some distinction; an early forebear was described as "gentleman," Henry VIII later gave the family lands, and its members held various offices. But family fortunes fell with the Puritan revolution in England, and John Washington, grandfather of Augustine, migrated in 1657 to Virginia. The ancestral home at Sulgrave, Northamptonshire, is maintained as a Washington memorial. Little definite information exists on any of the line until Augustine. He was an energetic, ambitious man who acquired much land, built mills, took an interest in opening iron mines, and sent his two oldest sons to England for schooling. By his first wife, Jane Butler, he had four children; by his second, six. Augustine died April 12, 1743.

Childhood and youth. Little is known of George Washington's early childhood, spent largely on the Ferry Farm on the Rappahannock River, opposite Fredericksburg, Virginia. Mason L. Weems's stories of the hatchet and cherry tree and of young Washington's repugnance to fighting are apocryphal efforts to fill a manifest gap. He attended *Schooling* school irregularly from his seventh to his 15th year, first with the local church sexton and later with a schoolmaster named Williams. Some of his schoolboy papers survive. He was fairly well trained in practical mathematics—gauging, several types of mensuration, and such trigonometry as was useful in surveying. He studied geography, possibly had a little Latin, and certainly read some of *The Spectator* and other English classics. The copybook in which he transcribed at 14 a set of moral precepts or *Rules of Civility and Decent Behaviour in Company and Conversation* was carefully preserved. His best training, however, was given him by practical men and outdoor occupations, not by books. He mastered tobacco growing and stock raising, and early in his teens he was sufficiently familiar with surveying to plot the fields about him.

At his father's death, the 11-year-old boy became the ward of his eldest half brother, Lawrence, a man of fine charac-*Lawrence* ter who gave him wise and affectionate care. Lawrence in-*Wash-* herited the beautiful estate of Little Hunting Creek, which *ington* had been granted to the original settler, John Washington, and which Augustine had done much since 1738 to develop. Lawrence married Anne (Nancy) Fairfax, daughter of Col. William Fairfax, cousin and agent of Lord Fairfax, one of the chief proprietors of the region. Lawrence also built a house and named the 2,500-acre holding Mount Vernon, in honour of the admiral under whom he had served in the siege of Cartagena. Living there chiefly with Lawrence (though he spent some time with his other half brother, Augustine, called Austin, near Fredericksburg), George entered a more spacious and polite world. Anne Fairfax Washington was a woman of charm, grace, and culture; Lawrence had brought from his English school and his naval service much knowledge and experience. A valued neighbour and relative, George William Fairfax, whose large estate, Belvoir, was about four miles distant, and other relatives by marriage, the Carlyles of Alexandria, helped form George's mind and manners.

The youth turned first to surveying as a profession. Lord Fairfax, a middle-aged bachelor who owned more than 5,000,000 acres in northern Virginia and the Shenandoah Valley, came to America in 1746 to live with his cousin George William at Belvoir and to look after his properties. Two years later he sent to the Shenandoah Valley a party to survey and plot his lands to make regular tenants of the squatters moving in from Pennsylvania. With the official surveyor of Prince William County in charge, Washington went along as assistant. The 16-year-old lad kept a disjointed diary of the trip, which shows skill in observation. He describes the discomfort of sleeping under "one thread Bear blanket with double its Weight of Vermin such as Lice Fleas & c"; an encounter with an Indian war party bearing a scalp; the Pennsylvania-German emigrants, "as ignorant a set of people as the Indians they would never speak English but when spoken to they speak all Dutch"; and the serving of roast wild turkey on "a Large Chip," for "as for dishes we had none."

The following year (1749), aided by Lord Fairfax, Washington received an appointment as official surveyor of Culpeper county, and for more than two years he was kept almost constantly busy. Surveying not only in Culpeper but also in Frederick and Augusta counties, he made journeys far beyond the tidewater region into the western wilderness. The experience taught him resourcefulness and endurance and toughened both body and mind. Coupled with his half brother Lawrence's ventures in land, it also gave him an interest in western development that endured throughout his life. He was always disposed to speculate in western holdings and to view favourably projects for colonizing the West, and he greatly resented the limitations that the crown in time laid on the westward movement. In 1752 Lord Fairfax determined to take up his final residence in the Shenandoah Valley and settled there in a log hunting lodge, which he called Greenway Court, after a Kentish manor of his family. There Washington was sometimes entertained and had access to a small library that Fairfax had begun accumulating at Oxford.

The years 1751–52 marked a turning point in Washing-*Mount* ton's life, for they placed him in control of Mount Vernon. *Vernon* His half brother Lawrence, stricken by tuberculosis, went to Barbados in 1751 for his health, taking George along. From this sole journey beyond the present borders of the United States, Washington returned with the light scars of an attack of smallpox. In July of the next year, Lawrence died, making George executor and residuary heir of his estate in the event of the decease of his daughter, Sarah, without issue. As she died within two months, Washington at the age of 20 became head of one of the best Virginia estates. He always thought farming the "most delectable" of pursuits. "It is honorable," he wrote, "it is amusing,

By courtesy of the Metropolitan Museum of Art, New York; Rogers Fund, 1907

Washington, oil painting by Gilbert Stuart, *c.* 1795. In the Metropolitan Museum of Art, New York.

and, with superior judgment, it is profitable." And of all the spots for farming, he thought Mount Vernon the best. "No estate in United America," he assured an English correspondent, "is more pleasantly situated than this." His greatest pride in later days was to be regarded as the first farmer of the land.

He gradually increased the estate until it exceeded 8,000 acres. He enlarged the house in 1760 and made further enlargements and improvements on the house and its landscaping in 1784–86. He tried to keep abreast of the latest scientific advances.

For the next 20 years the main background of Washington's life was the work and society of Mount Vernon. He had to manage the 18 slaves that came with the estate and others he bought later; by 1760 he paid tithes on 49 slaves—though he strongly disapproved of the institution and hoped for some mode of abolishing it. He gave assiduous attention to the rotation of crops, fertilization of the soil, and the management of livestock.

For diversion he was fond of riding, fox hunting, and dancing; of such theatrical performances as he could reach; and of duck hunting and sturgeon fishing. He liked billiards and cards and not only subscribed to racing associations but ran his own horses in races. In all outdoor pursuits, from wrestling to colt breaking, he excelled. A friend of the 1750s describes him as "straight as an Indian, measuring six feet two inches in his stockings"; as very muscular and broad shouldered, but though large boned, weighing only 175 pounds; and as having long arms and legs. His penetrating blue-gray eyes were overhung by heavy brows, his nose was large and straight, and his mouth was large and firmly closed. "His movements and gestures are graceful, his walk majestic, and he is a splendid horseman." He soon became prominent in community affairs, was an active member and later vestryman of the Episcopal Church, and as early as 1755 expressed a desire to stand for the Virginia House of Burgesses.

PREREVOLUTIONARY MILITARY AND POLITICAL CAREER

Early military career. Traditions of John Washington's feats as Indian fighter and Lawrence Washington's talk of service days helped imbue George with military ambition. Just after Lawrence's death, Lieut. Gov. Robert Dinwiddie appointed George adjutant for the southern district of Virginia at £100 a year (November 1752). The next year he became adjutant of the Northern Neck and Eastern Shore. Then in 1753 Dinwiddie found it necessary to warn the French to desist from their encroachments on Ohio Valley lands claimed by the crown; and after sending one messenger who failed to reach the goal, he determined to dispatch Washington. On the day he received his orders, October 31, 1753, Washington set out for the French posts. His party consisted of a Dutchman to serve as interpreter, the expert scout Christopher Gist as guide, and four others, two of them experienced traders with the Indians. Theoretically, Great Britain and France were at peace; but actually war impended, and Dinwiddie's message was an ultimatum: the French must get out or they would be put out.

Ohio Valley expedition The journey proved rough, perilous, and futile. Washington's party left what is now Cumberland, Maryland, in the middle of November and despite wintry weather and wilderness impediments reached Fort-Le Boeuf, at what is now Waterford, Pennsylvania, 20 miles south of Lake Erie, without delay. The French commander was courteous but adamant. As Washington reported, his officers "told me, That it was their absolute Design to take possession of the Ohio, and by God they would do it." Eager to carry this alarming news back, Washington pushed off hurriedly with Gist. He was lucky to get back alive. An Indian fired at them at 15 paces but missed; when they crossed the Allegheny River on a raft, Washington was jerked into the ice-filled stream but saved himself by catching one of the timbers. That night he almost froze in his wet clothing. He reached Williamsburg on January 16, 1754, where he hastily penned a record of the journey. Dinwiddie, who was labouring to convince the crown of the seriousness of the French threat, had it printed; and when he sent it to London, it was reprinted in three different forms.

The enterprising governor forthwith planned an expedition to hold the Ohio country. He made Joshua Fry colonel of a provincial regiment, appointed Washington lieutenant colonel, and set them to recruiting troops. Two agents of the Ohio Company, which Lawrence Washington and others had formed to develop lands on the upper Potomac and Ohio rivers, had begun building a fort at what later became Pittsburgh. Dinwiddie, ready to launch into his own war, sent Washington with two companies to reinforce this post. In April 1754 the lieutenant colonel set out from Alexandria with about 160 men at his back. He marched to Cumberland only to learn that the French had anticipated the British blow; they had taken possession of the fort of the Ohio Company and had renamed it Fort-Duquesne. Happily, the Indians of the area offered support. Washington therefore struggled cautiously forward to within about 40 miles of the French position and erected his own post at Great Meadows, near what is now Confluence, Pennsylvania. With this as base, he made a surprise attack (May 28, 1754) upon an advance detachment of 30 French, killing the commander, Coulon de Jumonville, and nine others and making the rest prisoners. The last French and Indian War had begun.

The last French and Indian War Washington at once received promotion to a full colonelcy and was reinforced, commanding a considerable body of Virginia and North Carolina troops, with Indian auxiliaries. But his attack soon brought the whole French force down upon him. They drove his 350 men into the Great Meadows fort (Ft. Necessity) on July 3, besieged it with 700 men, and, after an all-day fight, compelled him to surrender. The construction of the fort had been a blunder, for it lay in a waterlogged creek bottom, was commanded on three sides by forested elevations approaching it closely, and was too far from Washington's supports. The French agreed to let the disarmed colonials march back to Virginia with the honours of war, but they compelled Washington to promise that Virginia would not build another fort on the Ohio for a year and to sign a paper acknowledging responsibility for "*l'assassinat*" of de Jumonville, a word which Washington later explained he did not rightly understand. He returned to Virginia, chagrined but proud, to receive the thanks of the House of Burgesses, and to find that his name had been mentioned in the London gazettes. His remark in a letter to his brother that "I have heard the bullets whistle; and believe me, there is something charming in the sound" was commented on humorously by Horace Walpole and sarcastically by George II.

The arrival of Gen. Edward Braddock and his army in Virginia in February 1755, as part of the triple plan of campaign that called for his advance on Fort-Duquesne, Gov. William Shirley's capture of Niagara, and Sir William Johnson's capture of Crown Point, brought Washington new opportunities and responsibilities. He had resigned his commission in October 1754 in resentment of the slighting treatment and underpayment of colonial officers and particularly because of an untactful order of the British war office that provincial officers of whatever rank should be subordinate to any officer holding the king's commission. But he ardently desired a part in the war; "my inclinations," he wrote a friend, "are strongly bent to arms." When Braddock showed appreciation of his merits and invited him to join the expedition as personal aide-de-camp, with the courtesy title of colonel, he therefore accepted. His self-reliance, decision, and masterful traits soon became apparent.

At table he had frequent disputes with Braddock, who when contractors failed to deliver their supplies attacked the colonials as supine and dishonest while Washington defended them warmly. His freedom of utterance is proof of Braddock's esteem. Braddock accepted from him the unwise advice that he divide his army, leaving half of it to come up with the slow wagons and cattle train and taking the other half forward against Fort-Duquesne at a rapid pace. Washington was ill with fever when June but joined the advance guard in a covered wagon on July 8, begged to lead the march on Fort-Duquesne with his Virginians and the Indian allies, and was by Braddock's side when on July 9 the army was ambushed and bloodily defeated.

In this defeat Washington displayed the combination of coolness and determination, the alliance of unconquerable energy with complete poise, that was the secret of so many of his successes. So ill that he had to use a pillow instead of a saddle and that Braddock ordered his body servant to keep special watch over him, he was everywhere at once. At first he followed Braddock as the general bravely tried to rally his men to push either forward or backward, the wisest course the circumstances permitted. Then he rode back to bring up the Virginians from the rear and rallied them with effect on the flank. To him was largely due the escape of the force. His exposure of his person was as reckless as Braddock's, who was fatally wounded on his fifth horse; Washington had two horses shot under him and his clothes cut by four bullets without being hurt. He was at Braddock's deathbed, helped bring the troops back, and

Commander of the Virginia troops

was repaid by being appointed, in August 1755, while still only 23 years old, commander of all the Virginia troops. But no part of his later service was conspicuous. Finding that a Maryland captain who held a royal commission would not obey him, he rode north in February 1756 to Boston to have the question settled by the commander in chief in America, Governor Shirley, and, bearing a letter from Dinwiddie, had no difficulty in carrying his point. On his return he plunged into a multitude of vexations. He had to protect a weak, thinly settled frontier nearly 400 miles in length with only some 700 ill-disciplined colonial troops; to cope with a legislature unwilling to support him; to meet attacks on the drunkenness and inefficiency of the soldiers; and to endure constant wilderness hardships. It is not strange that in 1757 his health failed and in the closing weeks of that year he was so ill of a "bloody flux" that his physician ordered him home to Mount Vernon.

In the spring of 1758 he recovered sufficiently to return to duty as colonel in command of all Virginia troops. As part of the grand sweep of several British armies organized by Pitt, Gen. John Forbes led a new advance upon Fort-Duquesne. This time Forbes resolved not to use Braddock's road but to cut a new one west from Raystown, Pennsylvania. Washington disapproved of the route but played an important part in the movement. Late in the autumn the French evacuated and burned Fort-Duquesne, and Forbes reared Ft. Pitt on the site. Washington, who had just been elected to the House of Burgesses, was able to resign with the honorary rank of brigadier general.

Resignation from the colonial army

But though his officers expressed regret at the "loss of such an excellent Commander, such a sincere Friend, and so affable a Companion," he quit the service with a sense of frustration. He had thought the war excessively slow. The Virginia legislature had been niggardly in voting money; the Virginia recruits had come forward reluctantly and had proved of poor quality—he had hanged a few deserters and flogged others heavily. Virginia gave him less pay than other colonies offered their troops. Desiring a regular commission such as his half brother Lawrence had held, he applied in vain to the British commander in North America, Lord Loudoun, to make good a promise that Braddock had given him. Ambitious for both rank and honour, he showed a somewhat strident vigour in asserting his desires and in complaining when they were denied. He returned to Mount Vernon somewhat disillusioned.

Marriage and plantation life. Immediately on resigning his commission he was married (January 6, 1759) to Martha Dandridge, the widow of Daniel Parke Custis. She was a few months older than he, was the mother of two children living and two dead, and possessed one of the considerable fortunes of Virginia. Washington had met her the previous March and had asked for her hand before his campaign with Forbes. Though it does not seem to have been a romantic love match, the marriage united two harmonious temperaments and proved happy. Martha was a good housewife, an amiable companion, and a dignified hostess.

Some estimates of the property brought him by this marriage have been exaggerated, but it did include a number of slaves and about 15,000 acres, much of it valuable for its proximity to Williamsburg. More important to Washington were the two stepchildren, John Parke ("Jacky") and Martha Parke ("Patsy") Custis, who at the time of

the marriage were six and four, respectively. He lavished great affection and care upon them, worried greatly over Jacky's waywardness, and was overcome with grief when Patsy died just before the Revolution. Jacky died during the war, leaving four children. Washington adopted two of them, a boy and a girl, and even signed his letters to the boy as "your papa." Himself childless, he thus had a real family.

From the time of his marriage Washington added to the care of Mount Vernon the supervision of the Custis estate at the White House on the York River. As his holdings expanded they were divided into farms, each under its own overseer; but he minutely inspected operations every day and according to one visitor often pulled off his coat and performed ordinary labour. As he once wrote, "middling land under a man's own eyes, is more profitable than rich land at a distance." To the eve of the Revolution he devoted himself to the duties and pleasures of a great landholder, varied by several weeks' attendance every year in the House of Burgesses in Williamsburg. During 1760–74 he was also a justice of the peace for Fairfax County, sitting in court in Alexandria.

In no light does Washington appear more characteristically than as one of the richest, largest, and most industrious of Virginia planters. For six days a week he rose early and worked hard; on Sundays he irregularly attended Pohick Church (16 times in 1760), entertained company, wrote letters, made purchases and sales, and sometimes went fox hunting. In these years he took snuff and smoked a pipe; throughout life he liked Madeira wine and punch. Though wheat and tobacco were his staples, he practiced crop rotation on a three-year or five-year plan. He had his own waterpowered flour mill, blacksmith shop, brick and charcoal kilns, carpenters, and masons. His fishery supplied shad, bass, herring, and other catches, salted as food for the Negroes. Coopers, weavers, and his own shoemaker turned out barrels; cotton, linen, and woollen goods; and brogans for all needs. In short, his estates, in accordance with his orders to overseers to "buy nothing you can make yourselves," were largely self-sufficient communities. But he did send large orders to England for farm implements, tools, paint, fine textiles, hardware, and agricultural books and hence was painfully aware of British commercial restrictions.

He experimented in breeding cattle; acquired at least one buffalo, with the hope of proving its utility as a meat animal; and kept stallions at stud. He also took pride in a peach and apple orchard. His care of slaves was exemplary. He carefully clothed and fed them, engaged a doctor for them by the year, refused to sell them—"I am principled against this kind of traffic in the human species"—and administered correction mildly. They showed so much attachment that few ran away.

In the social life of the tidewater region he meanwhile played a prominent role. The members of the council and House of Burgesses, a roster of influential Virginians, were all friends. He visited the Byrds of Westover, the Lees of Stratford, the Carters of Shirley and Sabine Hall, and the Lewises of Warner Hall; Mount Vernon often was busy with guests in return. He liked house parties and afternoon tea on the Mount Vernon porch; he was fond of picnics, barbecues, and clambakes; and throughout life he enjoyed dancing, frequently going to Alexandria for balls. Cards were a steady diversion, and his accounts record sums lost at them, the largest reaching nearly £10. In bad weather his diary sometimes states, "at home all day, over cards." Billiards was a rival amusement. Not only the theatre, when available, but concerts, cockfights, the circus, puppet shows, and exhibitions of animals received his patronage.

He insisted on the best clothes—coats, laced waistcoats, hats, coloured silk hose—bought in London. The Virginia of the Randolphs, Corbins, Harrisons, Tylers, Nicholases, and other prominent families had an aristocratic quality, and Washington liked to do things in a large way. It has been computed that in the seven years prior to 1775, Mount Vernon had 2,000 guests, most of whom stayed to dinner if not overnight.

Prerevolutionary politics. Washington's contented life was interrupted by the rising storm in imperial affairs. The

British ministry, facing a heavy postwar debt, high home taxes, and continued military costs in America, decided in 1764 to obtain revenue from the colonies. Up to that time, Washington, though regarded by associates, in Col. John L. Peyton's words, as "a young man of an extraordinary and exalted character," had shown no signs of personal greatness and few signs of interest in state affairs. The Proclamation of 1763 interdicting settlement beyond the Alleghenies irked him, for he was interested in the Ohio Company, the Mississippi Company, and other speculative western ventures. He nevertheless played a silent part in the House of Burgesses and was a thoroughly loyal subject.

Anglo-
American
tensions

But he was present when Patrick Henry introduced his resolutions against the Stamp Act in May 1765 and shortly thereafter gave token of his adherence to the cause of the colonial Whigs against the Tory ministries of England. In 1768 he told George Mason at Mount Vernon that he would take his musket on his shoulder whenever his country called him. The next spring, April 4, 1769, he sent Mason the Philadelphia nonimportation resolutions with a letter declaring that it was necessary to resist the strokes of "our lordly masters" in England; that courteous remonstrances to Parliament having failed, he wholly endorsed the resort to commercial warfare; and that as a last resort no man should scruple to use arms in defense of liberty. When, the following May, the royal governor dissolved the House of Burgesses, he shared in the gathering at the Raleigh tavern that drew up nonimportation resolutions, and he went further than most of his neighbours in adhering to them. At that time and later he believed with most Americans that peace need not be broken.

Late in 1770 he paid a land-hunting visit to Ft. Pitt, where George Croghan was maturing his plans for the proposed 14th colony of Vandalia. Washington directed his agent to locate and survey 10,000 acres adjoining the Vandalia tract, and at one time he wished to share in certain of Croghan's schemes. But the Boston Tea Party of December 1773 and the bursting at about the same time of the Vandalia bubble turned his eyes back to the East and the threatening state of Anglo-American relations. He was not a member of the Virginia committee of correspondence formed in 1773 to communicate with other colonies, but when the Virginia legislators, meeting irregularly again at the Raleigh tavern in May 1774, called for a Continental Congress, he was present and signed the resolutions. Moreover, he was a leading member of the first provincial convention or revolutionary legislature late that summer, and to that body he made a speech that was much praised for its pithy eloquence, declaring that "I will raise one thousand men, subsist them at my own expense, and march myself at their head for the relief of Boston."

Delegate
to the
first Con-
tinental
Congress

The Virginia provincial convention promptly elected Washington one of the seven delegates to the first Continental Congress. He was by this time known as a radical rather than a moderate, and in several letters of the time he opposed a continuance of petitions to the British crown, declaring that they would inevitably meet with a humiliating rejection. " Shall we after this whine and cry for relief when we have already tried it in vain?" he wrote. When the congress met in Philadelphia on September 5, 1774, he was in his seat in full uniform, and his participation in its councils marks the beginning of his national career.

His letters of the period show that while still utterly opposed to the idea of independence, he was determined never to submit "to the loss of those valuable rights and privileges, which are essential to the happiness of every free State, and without which life, liberty, and property are rendered totally insecure." If the ministry pushed matters to an extremity, he wrote, "more blood will be spilled on this occasion than ever before in American history." Though he served on none of the committees, he was a useful member, his advice being sought on military matters and weight being attached to his advocacy of a nonexportation as well as nonimportation agreement. He also helped to secure approval of the "Suffolk Resolves," which looked toward armed resistance as a last resort and which did much to harden the king's heart against America.

Returning to Virginia in November, he took command of the volunteer companies drilling there and served as chairman of the committee of safety in Fairfax County. The unanimity with which the Virginia troops turned to him, though the province contained many experienced officers and Col. William Byrd of Westover had succeeded Washington as commander in chief, was a tribute to his reputation and personality; it was understood that Virginia expected him to be its general. At the March 1775 session of the legislature he was elected to the second Continental Congress and again set out for Philadelphia.

REVOLUTIONARY LEADERSHIP

Head of the colonial forces. Washington's choice as commander in chief of the military forces of all the colonies followed immediately upon the first fighting, though it was by no means inevitable and was the product of partly artificial forces. The Virginia delegates differed upon his appointment. Washington himself recommended Gen. Andrew Lewis for the post, and Edmund Pendleton was, according to John Adams, "very full and clear against it." It was chiefly the fruit of a political bargain by which New England offered Virginia the chief command as its price for the adoption and support of the New England army. This army had gathered hastily and in force about Boston immediately after the clash of British troops and American minutemen at Lexington and Concord on April 19, 1775. When the second Continental Congress met in Philadelphia on May 10, one of its first tasks was to find a permanent leadership for this force. On June 15, Washington, whose military counsel had already proved invaluable on two committees, was nominated and chosen by unanimous vote. Beyond the considerations noted, he owed his choice to the facts that Virginia stood with Massachusetts as one of the most powerful colonies; that his appointment would augment the zeal of the southern people; that he had made an enduring reputation in the Braddock campaign; and that his poise, sense, and resolution had impressed all the delegates. The scene of his election, with Washington darting modestly into an adjoining Election
as colonial
com-
mander room and John Hancock flushing with jealous mortification, will alway impress the historical imagination; so also will the scene of July 3, 1775, when wheeling his horse under an elm in front of the troops paraded on Cambridge common he drew his sword and took command of the army investing Boston. News of Bunker Hill had reached him before he was a day's jouney from Philadelphia, and he had expressed confidence of victory when told how the militia had fought. In accepting the command he refused any payment beyond his expenses and called upon "every gentleman in the room" to bear witness that he disclaimed fitness for it. At once he showed characteristic decision and energy in organizing the raw volunteers, collecting provisions and munitions, and rallying Congress and the colonies to his support.

The first phase of Washington's command covered the period from July 1775 to the British evacuation of Boston in March 1776. In those eight months he imparted discipline to the army, which at maximum strength slightly exceeded 20,000; he dealt with subordinates who, as John Adams said, quarrelled "like cats and dogs"; and he kept the siege vigorously alive. Having himself planned an invasion of Canada by Lake Champlain, to be entrusted to Gen. Philip Schuyler, he heartily approved of Benedict Arnold's proposal to march north along the Kennebec River and take Quebec. Giving Arnold 1,100 men, he instructed him to do everything possible to conciliate the Canadians. He was equally active in encouraging privateers to atack British commerce. As fast as means offered, he strengthened his army with ammunition and siege guns, bringing heavy artillery from Ticonderoga over the frozen roads early in 1776. His position was at first precarious, for the Charles River pierced the centre of his lines investing the town; and if the British general, Sir William Howe, had moved his 20 veteran regiments boldly up the stream, he might have pierced Washington's army and rolled either wing back to destruction. But all the generalship was on Washington's side. Seeing that Dorchester heights, just south of Boston, commanded the city and harbour and that Howe had unaccountably failed to occupy it, he seized it on the night of March 4, 1776, placing his Ticonderoga guns in

position. The British naval commander declared that he could not remain if the Americans were not dislodged, and Howe, after a storm disrupted his plans for an assault, evacuated the city on March 17. He left 200 cannon and invaluable stores of small arms and munitions. After stamping out the smallpox in Boston and collecting his booty, Washington hurried south to take up the defense of New York.

Washington had won the first round, but there remained five years of the war, during which the American cause was repeatedly near complete disaster. It is unquestionable that Washington's strength of character, his ability to hold the confidence of army and people and to diffuse his own courage among them, his unremitting activity, and his strong common sense constituted the chief factors in achieving American victory. He was not a great tactician: as Jefferson said later, he often "failed in the field"; he was sometimes guilty of grave military blunders, the chief being his assumption of a position on Long Island in 1776 that exposed his entire army to capture the moment it was defeated. At the outset he was painfully inexperienced, the wilderness fighting of the French war having done nothing to teach him the strategy of manoeuvring whole armies. One of his chief faults was his tendency to subordinate his own judgment to that of the generals surrounding him; at every critical juncture, before Boston, before New York, before Philadelphia, in New Jersey, he called a council of war and in almost every instance accepted its decision. Naturally bold and dashing, as he proved at Trenton, Princeton, and Germantown, he repeatedly adopted evasive and delaying tactics on the advice of his associates; however, he did succeed in keeping a strong army in existence and maintaining the flame of national spirit; and when the auspicious moment arrived, he planned the rapid movements that ended the war.

One element of Washington's strength was his sternness as a disciplinarian. The army was continually dwindling and refilling; politics largely governed the selection of officers by Congress and the states; and the ill-fed, ill-clothed, ill-paid forces were often half-prostrated by sickness and ripe for mutiny. Troops from each of the three sections, New England, the middle states, and the South, showed a deplorable jealousy of the others. Washington was rigorous in breaking cowardly, inefficient, and dishonest men and boasted in front of Boston that he had "made a pretty good sort of slam among such kind of officers." Deserters and plunderers were flogged, and Washington once erected a gallows 40 feet high, writing that "I am determined if I can be justified in the proceeding, to hang two or three on it, as an example to others." At the same time, the commander in chief won the devotion of many of his men by his earnestness in demanding better treatment for them from Congress. He complained of their short rations, declaring once that they were forced to "eat every kind of horse food but hay."

The darkest chapter in Washington's military leadership was opened when, reaching New York in April 1776, he placed half his army, about 9,000 men, under Israel Putnam, on the perilous position of Brooklyn Heights, Long Island, where a British fleet in the East River might cut off their retreat. He spent a fortnight in May with the Continental Congress in Philadelphia, then discussing the question of independence; and though no record of his utterances exists, there can be no doubt that he advocated complete separation. His return to New York preceded but slightly the arrival of the British army under Howe, which made its main encampment on Staten Island until its whole strength of nearly 30,000 could be mobilized. On August 22, 1776, Howe moved about 20,000 men across to Gravesend Bay on Long Island. Four days later, sending the fleet under command of his brother Adm. Richard Howe to make a feint against New York City, he thrust a crushing force along feebly protected roads against the American flank. The patriots were outmanoeuvred, defeated, and suffered a total loss of 5,000 men, of whom 2,000 were captured. Their whole position might have been carried by storm, but fortunately for Washington, General Howe delayed. While the enemy lingered, Washington succeeded under cover of a dense fog in ferrying

the remaining force across the East River to Manhattan, where he took up a fortified position. The British, suddenly landing on the lower part of the island, drove back the Americans in a clash marked by disgraceful cowardice on the part of Connecticut and other troops. In a series of actions, Washington was forced northward, more than once in danger of capture, until the loss of his two Hudson River forts, one of them with 2,600 men, compelled him to retreat from White Plains across the river into New Jersey. He retired toward the Delaware while his army melted away, until it seemed that armed resistance to the British was about to expire.

It was at this darkest hour of the Revolution that Washington struck his brilliant blows at Trenton and Princeton, reviving the hopes and energies of the nation. Howe, believing the American army soon would dissolve totally, retired to New York, leaving strong forces in Trenton and Burlington. Washington, at his camp west of the Delaware, planned a simultaneous attack on both posts, using his whole command of 6,000 men. But his subordinates in charge of both wings failed him, and he was left on the night of December 25, 1776, to march on Trenton with about 2,400 men. He completely surprised the unprepared Hessians and after confused street fighting killed the commander, Johann Rall, and captured 1,000 prisoners with arms and ammunition. The immediate result was that General Cornwallis hastened with 8,000 men to Trenton, where he found Washington strongly posted behind the Assunpink Creek, skirmished with him, and decided to wait overnight "to bag the old fox."

During the night, the wind shifted, the roads froze hard, and Washington was able to steal away from camp, leaving his fires deceptively burning, march around Cornwallis' rear and fall at daybreak upon the three British regiments at Princeton. These were put to flight with a loss of 500 men, and Washington escaped with more captured munitions to a strong position at Morristown, New Jersey. The effect of these victories heartened all Americans, brought recruits flocking to camp in the spring, and encouraged foreign sympathizers with the American cause.

Thus far the important successes had been won by Washington; then they fell to others, while he was left to face popular apathy, military cabals, and the disaffection of Congress. The year 1777 was marked by the British capture of Philadelphia and the surrender of Gen. John Burgoyne's invading army to Gen. Horatio Gates at Saratoga followed by intrigues to displace Washington from his command. Howe's main British army of 18,000 left New York by sea on July 23, 1777, and landed on August 25 in Maryland, not far below Philadelphia. Washington, despite his inferiority of force, for he had only 11,000 men, mostly militia and in Lafayette's words "badly armed and worse clothed," risked a pitched battle on September 11 at the fords of Brandywine Creek, about 13 miles north of Wilmington. While part of the British force held the Americans engaged, Gen. Charles Cornwallis, with the rest, made a secret 17-mile detour and fell with crushing effect on the American right and rear, the result being a complete defeat from which Washington was fortunate to extricate his army in fairly good order. For a time he hoped to hold the Schuylkill Fords, but the British passed them and on September 26 triumphantly marched into Philadelphia. Congress fled to the interior of Pennsylvania, and Washington, after an unsuccessful effort to repeat his stroke at Trenton against the British troops posted at Germantown, had to take up winter quarters at Valley Forge. His army, twice beaten, ill housed, and ill fed, with thousands of men "barefoot and otherwise naked," was at the point of exhaustion; it could not keep the field, for inside of a month it would have disappeared. Under these circumstances, there is nothing that better proves the true fibre of Washington's character and the courage of his soul than the unyielding persistence with which he held his strong position at Valley Forge through a winter of semi-starvation, of justified grumbling by his men, of harsh public criticism, and of captious meddling by a Congress that was too weak to help him.

Washington's enemies seized the moment of his greatest weakness to give vent to an antagonism that had been

Plot to
displace
Wash-
ington

nourished by sectional jealousies of north against south, by the ambition of small rivals, and by baseless accusations that he showed favouritism to such foreigners as Lafayette. The intrigues of Thomas Conway, an Irish adventurer who had served in the French army and had become American inspector general, enlisted Thomas Mifflin, Charles Lee, Benjamin Rush, and others in an attempt to displace Washington. General Gates appears to have been a tool of rather than a party to the plot, expecting that the chief command would devolve upon himself. A faction of Congress sympathized with the movement and attempted to paralyze Washington by reorganizing the board of war, a body vested with the general superintendence of operations, of which Gates became president; his chief of staff, James Wilkinson, the secretary; and Mifflin and Timothy Pickering, members. Washington was well aware of the hostility in congress, of the slanders spread by Benjamin Rush and James Lovell of Massachusetts, and of the effect of forgeries published in the American press by adroit British agents. He realized the intense jealousy of many New Englanders, which made even John Adams write his wife that he was thankful Burgoyne had not been captured by Washington, who would then "have been deified. It is bad enough as it is." But Washington decisively crushed the cabal when, the loose tongue of Wilkinson having disclosed Conway's treachery, he sent the latter officer on November 9, 1777, proof of his knowledge of the whole affair.

With the conclusion of the French alliance in the spring of 1778, the aspect of the war was radically altered; and the British army in Philadelphia, fearing that a French fleet would blockade the Delaware while the militia of New Jersey and Pennsylvania invested the city, hastily retreated upon New York City. Washington hoped to cut off part of the enemy by a hurried march with six brigades interposed himself at the end of June between Sir Henry Clinton (who had succeeded Howe) and the Jersey coast. The result was the Battle of Monmouth ● June 28, where a shrewd strategic plan and vigorous assault were brought to naught by the treachery of Charles Lee. When Lee ruined the attack by a sudden order to retreat, Washington hurried forward, fiercely denounced him, and restored the line, but the golden opportunity had been lost. The British made good their march to Sandy Hook, and Washington took up his quarters at New Brunswick. Lee was arrested, court-martialled, and convicted on all three of the charges made against him; but instead of being shot, as he deserved, he was sentenced to a suspension from command for one year. The arrival of the French fleet under Adm. Charles-Hector Estaing on July 1778 completed the isolation of the British, and Clinton was thenceforth held to New York City and the surrounding area. Washington made his headquarters in the highlands of the Hudson and distributed his troops in cantonments around the city and in New Jersey.

Yorktown
and
the end
of the war

The final decisive stroke of the war, the capture of Cornwallis at Yorktown, is to be credited chiefly to Washington's vision. With the domestic situation intensely gloomy early in 1781, he was hampered by the feebleness of Congress, the popular discouragement, and the lack of prompt and strong support by the French fleet. A French army under Comte de Rochambeau having arrived to reinforce him in 1780, he pressed Admiral de Grasse to assist in an attack upon either Cornwallis in the south or Clinton in New York. In August the French admiral sent definite word that he preferred the Chesapeake, with its large area and deep water, as the scene of his operations; and within a week, on August 19, 1781, Washington marched south with his army, leaving Gen. William Heath with 4,000 men to hold West Point. He hurried his troops through New Jersey, embarked them on transports in Delaware Bay, and landed them at Williamsburg, Virginia, where he had arrived on September 14. Cornwallis had retreated to Yorktown and entrenched his army of 7,000 British regulars. Their works were completely invested before the end of the month; the siege was pressed with vigour by the allied armies under Washington, consisting of 5,500 Continentals, 3,500 Virginia militia, and 5,000 French regulars; and on October 19 Cornwallis surrendered. By this cam-

paign, probably the finest single display of Washington's generalship, the war was brought to a virtual close.

Washington remained during the winter of 1781–82 with the Continental Congress in Philadelphia, exhorting it to maintain its exertions for liberty and to settle the army's claims for pay. He continued these exhortations after he joined his command at Newburgh on the Hudson in April 1782. He was astounded and angered when some loose camp suggestions found expression in a letter from Col. Lewis Nicola offering a plan by which he should use the army to make himself king. He blasted the proposal with fierce condemnation. When the discontent of his unpaid men came to a head in the circulation of the "Newburgh Address" early in 1783, he issued a general order censuring the paper and at a meeting of officers on March 15 read a speech admonishing the army to obey Congress and promising his best efforts for a redress of grievances. He was present at the entrance of the American army into New York on the day of Clinton's evacuation, November 25, 1783, and on December 4 took leave of his closest officers in an affecting scene at Fraunces' tavern. Travelling south, on December 23, in a solemn ceremonial immortalized by the pen of William Makepeace Thackeray, he resigned his commission to the Continental Congress in the state senate chamber of Maryland in Annapolis and received the thanks of the nation. His accounts of personal expenditures during his service, kept with minute exactness in his own handwriting and totalling £24,700, without charge for salary, had been given the controller of the treasury to be discharged. Washington left Annapolis at sunrise of December 24 and before nightfall was at home in Mount Vernon.

Return
to Mount
Vernon

In the next four years Washington found sufficient occupation in his estates, wishing to close his days as a gentleman-farmer and giving to agriculture as much energy and thought as to the army. He enlarged the Mount Vernon house; he laid out the grounds anew, with sunken walls, or ha-has; and he embarked on experiments with mahogany, palmetto, pepper, and other foreign trees, English grasses and grains. His farm manager during the Revolution, a distant relative named Lund Washington, retired in 1785 and was succeeded by a nephew, Maj. George Augustine Washington, who resided at Mount Vernon until his death, in 1792. Washington's losses during the war had been heavy, caused by neglect of his lands, stoppage of exportation, and a depreciation of paper money, which cost him hardly less than $30,000. He then attempted successfully to repair his fortunes, his annual receipts from all his estates being from $10,000 to $15,000 a year. In 1784 he made a tour of nearly 700 miles to view the wild lands he owned to the westward, Congress having made him a generous grant. As a national figure, he was constrained to offer hospitality to old army friends, visitors from other states and nations, diplomats, and Indian delegations, and he and his household seldom sat down to dinner alone.

PRESIDENCY

Postrevolutionary politics. Viewing the chaotic political condition of the United States after 1783 with frank pessimism and declaring (May 18, 1786) that "something must be done, or the fabric must fall, for it is certainly tottering," Washington repeatedly wrote his friends urging steps toward "an indissoluble union." At first he believed that the Articles of Confederation might be amended. Later, especially after the shock of Shays's rebellion, he took the view that a more radical reform was necessary but doubted as late as the end of 1786 that the time was ripe. His progress toward adoption of the idea of a federal convention was, in fact, puzzlingly slow. Though John Jay assured him in March 1786 that breakup of the nation seemed near and opinion for the convention was crystallizing, Washington remained noncommittal. But despite long hesitations, he earnestly supported the proposal for a federal impost, warning the states that their policy must decide "whether the Revolution must ultimately be considered a blessing or a curse." And his numerous letters to the leading men of the country assisted greatly to form a sentiment favourable to a more perfect union.

Some understanding being necessary between Virginia and Maryland regarding the navigation of the Potomac, commissioners from the two states met at Mount Vernon in the spring of 1785; from this seed sprang the federal convention. Washington approved in advance the call for a gathering of all the states to meet in Philadelphia in May 1787 to "render the Constitution of the Federal Government adequate to the exigencies of the Union." But he was again hesitant about attending, partly because he felt tired and infirm, partly because of doubts about the outcome. Although he hoped to the last to be excused, he was chosen one of Virginia's five delegates.

Washington arrived in Philadelphia on May 13, the day before the opening of the Convention, and as soon as a quorum was obtained he was unanimously chosen its president. For four months he presided over the Constitutional Convention, breaking his silence only once upon a minor question of congressional apportionment. Though he said little in debate, no one did more outside the hall to insist on stern measures. "My wish is," he wrote, "that the convention may adopt no temporizing expedients, but probe the defects of the Constitution to the bottom, and provide a radical cure." His weight of character did more than any other single force to bring the convention to an agreement and obtain ratification of the instrument afterward. He did not believe it perfect, though his precise criticisms of it are unknown. But his support gave it victory in Virginia, where he sent copies to Patrick Henry and other leaders with a hint that the alternative to adoption was anarchy, declaring that "it or dis-union is before us to chuse from," told powerfully in Massachusetts. He received and personally circulated copies of *The Federalist*. When once ratification was obtained, he wrote leaders in the various states urging that men staunchly favourable to it be elected to Congress. For a time he sincerely believed that, the new framework completed, he would be allowed to retire again to privacy. But all eyes immediately turned to him for the first president. He alone commanded the respect of both the parties engendered by the struggle over ratification, and he alone would be able to give prestige to the republic throughout Europe. In no state was any other name considered. The electors chosen in the first days of 1789 cast a unanimous vote for him, and reluctantly— for his love of peace, his distrust of his own abilities, and his fear that his motives in advocating the new government might be misconstrued all made him unwilling— he accepted.

On April 16, after receiving congressional notification of the honour, he set out from Mount Vernon, reaching New York in time to be inaugurated on April 30. The ceremony was performed in Wall Street, near the spot now marked by Ward's statue of Washington; and a great crowd broke into cheers as, standing on the balcony of Federal Hall, he took the oath administered by Chancellor Robert Livingston and retired indoors to read Congress his inaugural address.

The Washington administration. Washington's administration of the government in the next eight years was marked by the caution, the methodical precision, and the sober judgment that had always characterized him. He regarded himself as standing aloof from party divisions and emphasized his position as president of the whole country by a tour first through the Northern states and later through the Southern. A painstaking inquiry into all the problems confronting the new nation laid the basis for a series of judicious recommendations to Congress in his first message. In selecting the four members of his first cabinet, Thomas Jefferson as secretary of state, Alexander Hamilton as secretary of treasury, Henry Knox as secretary of war, and Edmund Randolph as attorney general, Washington balanced the two parties evenly. But he leaned with especial weight upon Hamilton, supporting his scheme for the assumption of state debts, taking his view that the bill establishing the Bank of the United States was constitutional, and in general strengthening the authority of the federal government.

Distressed when the inevitable clash between Jefferson and Hamilton arose, he tried to keep harmony, writing frankly to each and refusing to accept their resignations.

But when war was declared between France and England in 1793, he again took Hamilton's view that the United States should completely disregard the treaty of alliance with France and pursue a course of strict neutrality, while he acted decisively to stop the improper operations of the French minister, Edmund-Charles Genet. He had a firm belief that the United States must insist on its national identity, strength, and dignity. His object, he wrote, was to keep the country "free from political connections with *every* other country, to see them independent of all, and under the influence of none. In a word, I want an *American* character that the powers of Europe may be convinced that we act for *ourselves*, and not for others." The sequel was the resignation of Jefferson at the close of 1793, the two men parting on good terms and Washington praising Jefferson's "integrity and talents." The suppression of the Whisky Insurrection in 1794 by federal troops whom Hamilton led in person and the dispatch of John Jay to conclude a treaty of commerce with Great Britain tended further to align Washington with the Federalist Party. Though the general voice of the people compelled him to acquiesce reluctantly to a second term in 1792 and his election that year was again unanimous, during his last four years in office he suffered from a fierce personal and partisan animosity. This culminated when the publication of the terms of the Jay Treaty, which Washington signed on June 25, 1794, provoked a bitter discussion, and the house of representatives called upon the president for the instructions and correspondence relating to the treaty. These Washington, who had already clashed with the Senate on foreign affairs, refused to deliver; and in the face of an acrimonious debate, he firmly maintained his position.

Early in his first term, Washington, who by education and natural inclination was minutely careful of the proprieties of life, established the rules of a virtual republican court. In both New York and Philadelphia he rented the best houses procurable, refusing to accept the hospitality of George Clinton, for he believed the head of the nation should be no man's guest. He returned no calls and shook hands with no one, acknowledging salutations by a formal bow. He drove in a coach drawn by four or six smart horses, with outriders and lackeys in rich livery. He attended receptions dressed in a black velvet suit with gold buckles, with yellow gloves, powdered hair, a cocked hat with an ostrich plume in one hand and a sword in a white leather scabbard. After being overwhelmed by callers, he announced that except for a weekly levee open to all, persons desiring to see him must make previous engagements. On Friday afternoons the First Lady held informal receptions, at which the President appeared. Though the presidents of the Continental Congress had made their tables partly public, Washington, who entertained largely, inviting members of Congress in rotation, insisted that his hospitality be private. He served good wines and the menus were elaborate, but such visitors as Senator Maclay complained that the atmosphere was too "solemn." Indeed, his simple ceremony offended many of the more radical anti-Federalists, who did not share his sense of its fitness and accused the president of conducting himself as a king. But his cold and reserved manner was caused by native diffidence rather than any excessive sense of dignity.

Retirement. Earnestly desiring leisure, feeling a decline of his physical powers, and wincing under opposition abuse, Washington refused to yield to the general pressure for a third term. This refusal was blended with a testament of sagacious advice to his country in the *Farewell Address* of September 19, 1796, written largely by Hamilton but remolded by Washington and expressing his ideas. Retiring in March 1797 to Mount Vernon, he devoted himself for the last two and a half years of his life to his family, farm operations, and care of his slaves. In 1798 his seclusion was briefly interrupted when the prospect of war with France caused his appointment as commander in chief of the provisional army, and he was much worried by the political quarrels over high commissions; but the war cloud passed away. On December 12, 1799, he exposed himself on horseback for several hours to cold and snow and, returning home exhausted, was attacked late next day with quinsy or acute laryngitis. He was bled heavily four

Margin notes:

Election as President of the United States

Second term

times and given gargles of "molasses, vinegar and butter," and a blister of cantharides (a preparation of dried beetles) was placed on his throat, his strength meanwhile rapidly sinking. He faced the end with characteristic serenity, saying, "I die hard, but I am not afraid to go," and later "I feel myself going. I thank you for your attentions; but I pray you to take no more trouble about me. Let me go off quietly. I cannot last long." After giving instructions to his secretary, Tobias Lear, about his burial, he died at 10:00 PM on December 14. The news of his death placed the entire country in mourning, and the sentiment of the country endorsed the famous words of Henry Lee, embodied in resolutions which John Marshall introduced in the house of representatives, that he was "first in war, first in peace, and first in the hearts of his countrymen." When the news reached Europe, the British channel fleet and the armies of Napoleon paid tribute to his memory, and many of the leaders of the time joined in according him a preeminent place among the heroes of history.   (Al.N.)

BIBLIOGRAPHY.   The earliest known portrait of Washington is that by Charles Willson Peale, painted in 1772. A long line of painters and sculptors followed, and their work may be found reproduced in GUSTAVUS A. EISEN *et al.*, *Portraits of Washington*, 3 vol. (1932); and criticized in JUSTIN WINSOR (ed.), *Narrative and Critical History of America,* vol. 7 (1888, reprinted 1967). Washington himself thought highly of the likeness by Joseph Wright, painted in 1782. According to Winsor, the favourite profile is Jean-Antoine Houdon's, while Gilbert Stuart's canvas has been popularly preferred for the full face and John Trumbull's florid paintings for the whole figure. Stuart's pictures are somewhat idealized, while all the later portraits suffer from the fact that the artificial teeth worn by Washington in later years altered the expression of his face. Houdon's statue hardly does justice to Washington's imposing stature, dignified carriage, and great poise. But the Houdon bust, modeled from life, is excellent.

JOHN C. FITZPATRICK (ed.), *The Writings of George Washington from the Original Manuscript Sources, 1745–1799,* 39 vol. (1931–44, reprinted 1972), is a full compilation, excluding only the diaries; these were published seperately as *Diaries of George Washington, 1748–1799,* ed. by JOHN C. FITZPATRICK, 4 vol. (1925, reissued 1971); and *The Diaries of George Washington,* ed. by DONALD JACKSON and DOROTHY TWOHIG, 6 vol. (1976–79). *The Journal of the Proceedings of the President, 1793–1797,* ed. by DOROTHY TWOHIG (1981), is an annotated executive daybook covering years for most of which the diaries have not been found. A more recent edition of Washington's correspondence and documents is *The Papers of George Washington,* in four separate series: *Colonial Series,* ed. by W.W. ABBOT *et al.* (1983–), *Revolutionary War Series,* ed. by PHILANDER D. CHASE (1985–), *Confederation Series,* ed. by W.W. ABBOT *et al.* (1992–), and *Presidential Series,* ed. by DOROTHY TWOHIG (1987–).

Washington generated a significant amount of debate and scholarly and popular writing beginning in the 1990s. These works include RICHARD BROOKHISER, *Founding Father: Rediscovering George Washington* (1996); WILLIAM MARTIN, *Citizen Washington: A Novel* (1999); PETER HANNAFORD (compiler and ed.), *The Essential George Washington: Two Hundred Years of Observations on the Man, the Myth, the Patriot* (1999); STUART LEIBIGER, *Founding Friendship: George Washington, James Madison, and the Creation of the American Republic* (1999); BARBARA J. MITNICK (ed.), *George Washington: American Symbol* (1999); FRITZ HIRSCHFELD, *George Washington and Slavery: A Documentary Portrayal* (1997); DON HIGGINBOTHAM (ed.), *George Washington Reconsidered* (2001); JOHN RHODEHAMEL, *The Great Experiment: George Washington and the American Republic* (1998); PAUL K. LONGMORE, *The Invention of George Washington* (1998, reissued 1999); and GARY L. GREGG and MATTHEW SPALDING (eds.), *Patriot Sage: George Washington and the American Political Tradition* (1999). The rules of civility and behaviour that Washington transcribed when he was 14 years old can be found in STEVEN MICHAEL SELZER, *By George!: Mr. Washington's Guide to Civility Today* (2000).

An excellent biography is DOUGLAS SOUTHALL FREEMAN, *George Washington, A Biography,* 7 vol. (1948–57)—vol. 7 was written by J.A. CARROLL and M.W. ASHWORTH. M.L. WEEMS, *A History of the Life and Death, Virtues and Exploits, of General*

George Washington (1800), was the first edition of the utterly unreliable but most widely distributed early biography, which has been reissued in numerous later editions, often titled *The Life of Washington;* the 5th ed., retitled *The Life of George Washington the Great* (1806), introduced the fictitious anecdote about the hatchet and the cherry tree. Among the best modern works are SHELBY LITTLE, *George Washington* (1929, reissued 1962); JOHN C. FITZPATRICK, *George Washington Himself* (1933, reprinted 1975); JAMES THOMAS FLEXNER, *George Washington: The Forge of Experience, 1732–1775* (1965), *George Washington in the American Revolution, 1775–1783* (1968, reissued 1972), *George Washington and the New Nation, 1783–1793* (1970), *George Washington: Anguish and Farewell (1793–1799)* (1972), and *Washington: The Indispensable Man* (1974, reissued 1984); MARCUS CUNLIFFE, *George Washington, Man and Monument,* rev. ed. (1982); and RICHARD BROOKHISER, *Founding Father: Rediscovering George Washington* (1996). Other works dealing with Washington's life and career are CHARLES CECIL WALL, *George Washington, Citizen-Soldier* (1980), emphasizing his personal life; JOHN R. ALDEN, *George Washington: A Biography* (1984), with focus on his role in the military and as president; ROBERT F. JONES, *George Washington,* rev. ed. (1986); and JOHN E. FERLING, *The First of Men: A Life of George Washington* (1988), seeking the correlation between the man and his career. David Humphreys' *Life of General Washington: With George Washington's "Remarks,"* ed. by ROSEMARIE ZAGARRI (1991), compiles biographical details written in 1787–89 by a Washington aide-de-camp, complete with Washington's comments and corrections.

Washington's presidency is examined in THOMAS G. FROTHINGHAM, *Washington, Commander in Chief* (1930); FORREST MCDONALD, *The Presidency of George Washington* (1974, reissued 1988), a study of the political and economic aspects of his administration; FRANK T. REUTER, *Trials and Triumphs: George Washington's Foreign Policy* (1983), a useful introductory study; and RICHARD NORTON SMITH, *Patriarch: George Washington and the New American Nation* (1993), with a detailed treatment of Washington's presidential days. Washington's role in determining the focus and development of the U.S. Constitution is discussed in JOHN CORBIN, *The Unknown Washington* (1930, reprinted 1972); and GLENN A. PHELPS, *George Washington and American Constitutionalism* (1993). Analyses of his military career can be found in CHARLES H. AMBLER, *George Washington and the West* (1936, reprinted 1971); HUGH CLELAND, *George Washington in the Ohio Valley* (1955); GEORGE ATHAN BILLIAS (ed.), *George Washington's Generals* (1964, reprinted 1994), with an essay on Washington's generalship; BURKE DAVIS, *George Washington and the American Revolution* (1975), an account of his role as military commander; EDMUND S. MORGAN, *The Genius of George Washington* (1980), a brief study; DON HIGGINBOTHAM, *George Washington and the American Military Tradition* (1985), examining his public life and life in the military prior to becoming president; and THOMAS A. LEWIS, *For King and Country: The Maturing of George Washington, 1748–1760* (1993), with emphasis on the French and Indian War. Valuable studies on special aspects of Washington's life include PAUL LELAND HAWORTH, *George Washington, Farmer* (1915, reissued as *George Washington, Country Gentleman,* 1925); EUGENE E. PRUSSING, *The Estate of George Washington, Deceased* (1927); HALSTED L. RITTER, *Washington as a Business Man* (1931); and CHARLES WYLLYS STETSON, *Washington and His Neighbors* (1956).

PAUL LEICESTER FORD, *The True George Washington* (1896, reprinted 1971; also published as *George Washington,* 1970), is a classic examination of all sides of Washington's career and personality. CHARLES MOORE, *The Family Life of George Washington* (1926), takes a look at the president's private life. PAUL K. LONGMORE, *The Invention of George Washington* (1988), suggests that Washington created his own public image. That public image and its meaning are further analyzed in GARRY WILLS, *Cincinnatus: George Washington and the Enlightenment* (1984); and BARRY SCHWARTZ, *George Washington: The Making of an American Symbol* (1987).

ANNE HOLLINGSWORTH WHARTON, *Martha Washington* (1897, reprinted 1968), is excellent; it is supplemented by PAUL WILSTACH, *Mount Vernon: Washington's Home and the Nation's Shrine* (1916, reissued 1930). Correspondence to and from Martha Washington, 1757–1802, is found in JOSEPH E. FIELDS (compiler), *Worthy Partner: The Papers of Martha Washington* (1994).   (Al.N./Ed.)

Washington, D.C.

The capital of the United States of America, the city of Washington is coextensive with the District of Columbia. It is located at the head of navigation of the Potomac River, which separates it from Virginia to the southwest. In 1790 Congress designated 100 square miles (260 square kilometres) of territory for the seat of government on land ceded by Maryland and Virginia; however, in the mid-19th century the land south of the Potomac River was returned to Virginia. Since then the district's boundaries have made it essentially a 68-square-mile enclave carved from Maryland. The greater Washington metropolitan area includes several surrounding counties in Virginia and Maryland and such Virginia cities as Fairfax, Falls Church, and Alexandria.

This article is divided into the following sections:

Physical and human geography

CHARACTER OF THE CITY

Washington is one of the few capital cities of the world founded expressly as a seat of government and as a centre for international representation. The expansive designs for the city were to symbolize the ideals of the freedom so recently achieved yet still so tenuously held by the citizenry of the nation. It was to be a vital city, the proper seat for the federal government.

The modern city also holds the nation's most sacred monuments and the most meaningful artifacts of its history, the embassies of foreign nations, and an impressive collection of the national art treasures. Nearly every significant national organization has its headquarters or a major branch in the District, often for the purpose of lobbying in Congress or within federal agencies. The city was meant to be, and has remained, the focal point of the nation for sightseers and for seekers after the spirit of the American past and present.

Impediments to municipal development. For many reasons, Washington has had a development that is unique among the world's major cities. As the capital city of arguably the most influential country in the world, Washington, D.C.—and its scores of politicians, notable residents, distinguished visitors, and national and interna-

tional organizations—is forever in the spotlight. As a result, it is a city with multiple personalities: a working federal city, an international metropolis, a picturesque tourist mecca and treasury of the nation's heritage, and, for some, a neighbourly hometown. Washington also has a complex admixture of political, economic, and social concerns. The city is located near the end of the sprawling urbanized agglomeration that spreads southward from Boston along the Eastern Seaboard, and it has most of the same problems that face other great core metropolises of the region—Boston, New York City, Philadelphia, and Baltimore—and of the nation as a whole.

Another set of disparities exists between the city of Washington and the Washington metropolitan area. More than one-fourth of the people over 26 years of age in the metropolitan area hold college degrees, the highest proportion among the 10 largest such areas in the country, and the area's population has one of the highest annual per capita incomes. On the other hand, a high percentage of the population within the city is made up of families with low incomes or of handicapped or aged persons, many requiring governmental assistance.

These factors provide insight into why Washington—the city as distinct from the capital and the metropolitan area—has developed neither the social stability nor the continuity that provides the lifeblood of most other large cities. Both the living and working populations of Washington are among the most transient in the nation. Only a small percentage of residents have longtime roots in Washington, while a high proportion of government and service workers commute into the city from suburban homes. These more affluent Washington workers typically spend most of their income and pay most of their taxes in adjacent counties and states.

The incomplete city. With its history and character so profoundly affected by the varying and nonlocal interests and values of Congress, however, concern for Washington's social and environmental quality has been limited. Approximately half of the land in Washington is owned by the U.S. government, which pays no taxes. An additional tenth of the land is untaxed because it is owned by foreign governments and nonprofit institutions. The prominence of the park and highway systems in the city's landscape reflects the interests of Congress and various federal agencies, but the historic lack of concern for the city as a whole has left the grandeur of its vistas, monuments, and governmental facilities in startling contrast to the large areas of the city that have struck many observers as being in various stages of physical and spiritual distress.

THE LANDSCAPE

The city layout. Washington's city plan is remarkable and unique. The city's visionary was Pierre-Charles L'Enfant, a French army engineer who served honourably in the American Revolution. L'Enfant perfectly adapted the city's formal plan to the area's natural topography, carefully selecting important sites for principal buildings by the order of their importance, beginning with the Capitol. He connected these sites with long and broad avenues, thereby forming "lines of direct communication" yet symbolically separating the governmental powers. (Ri.W.S./Ed.)

Two elements of the original plan for Washington, completed in 1791, are of special significance. First, L'Enfant's ideas for a capital city were based not on 13 colonies with 3,000,000 inhabitants but on a republic ultimately having 50 states and 500,000,000 citizens. He envisioned a city of 800,000 inhabitants at a time when the entire United States had less than four times that number. Second, L'Enfant had reached artistic maturity in Paris and Versailles, where he was influenced strongly by Baroque landscape architecture, which was at its zenith in the

Concepts underlying L'Enfant's designs

House of Representatives the right. The Supreme Court is at upper left and buildings of the
Library of Congress at upper right.
H Armstrong Roberts

late decades of the 18th century. His original designs for Washington reflected the grandeur both of his projections and of the Baroque.

L'Enfant's basic plan. Perhaps the dominant element in L'Enfant's designs is the complex revolving about the Capitol, the Mall, and the executive mansion, which came to be known as the White House. Both buildings, incorporating elements of Baroque design, were placed to form the background, or terminating vista, of long straight pathways, or malls. Radiating from the buildings were two series of broad avenues converging into circular intersections, the effect of which was to create, in L'Enfant's phrase, "a reciprocity of view," a means of terminating long vistas that would give direction and character to the city and would create throughout it a series of subcentres within view of one another. Most of these subcentres—now circles and squares with small green parks—were carefully located on natural rises in the terrain, as were the Capitol and the White House.

The Mall, which extends from the Capitol to the Lincoln Memorial, was intended to be one broad, tree-lined avenue, in the manner of the Champs-Élysées in Paris, rather than the green lawn, with occasional buildings and a crisscross of roads, that it has become. At the point where the north–south axis of the White House meets the east–west axis of the Capitol, an equestrian statue of George Washington was planned. This spot, slightly relocated because of soft subsoil and subterranean streams, is now the site of the Washington Monument.

Avenues, streets, and quadrants   The pattern of radiating avenues was to be joined and filled by a gridiron matrix of streets. With the Capitol as the axis, the streets were lettered to the north and south, numbered to the east and west, and the avenues were named for the states. The entire city was divided into northwest (NW), northeast (NE), southeast (SE), and southwest (SW) quadrants, also centred on the Capitol. L'Enfant's plan ended to the north at what became Florida Avenue, where a steep bluff was to provide the approaching traveller with the impressive expanse of the city spread out at his feet.

Subsequent development. Even before the Capitol's cornerstone was laid, L'Enfant had been dismissed reluctantly after disagreements with the commissioners in charge of raising the public buildings. During the 19th century and later, the original harmony of his design was eroded with the emergence of new municipal and governmental functions. Awkward relations developed between the grid pattern of cross streets and the diagonal avenues, especially at intersections, while the circular intersections, though providing pleasant oases for pedestrians, were fed by too many streets in the unforeseen age of the automobile and consequently became impediments along the city's thoroughfares. The original plan was effectively lost until 1887, when its recovery revealed that a number of 19th-century buildings along Pennsylvania Avenue, around the White House, and on Capitol Hill had altered the symmetries of the original conception.

The addition of trees along most major avenues and streets, though now a feature of the city, destroyed in great part the concept of a city of magnificent distances. The location of other notable monuments, especially the Lincoln and Jefferson memorials and the John F. Kennedy Center for the Performing Arts, modified the original plan further, as did the placement of various museums and temporary buildings on the Mall. Whatever the impact of later alterations, however, only a few efforts have been made since L'Enfant to redesign the capital totally.

Continuing affective elements of the capital. To the visitor, nothing is more expressive of Washington's character than the dozens of buildings and hundreds of monuments that relate to its functions as the nation's capital. The style of federal architecture has changed several times over the years, and L'Enfant's plans for the location of the Capitol and the White House remain as focal points for a complexity of monuments and buildings that retain a kind of basic coherence to the image of Washington as a capital city.

Dominating the scene, the Capitol offers an impressive silhouette terminating the Mall. Criticized by many as a "potpourri of many chefs," the Capitol may lack the authenticity of the massive Renaissance domes that inspired it, but to many others it offers a feeling of emotional assurance that representative government rests on a broad and solid foundation. The other original building that

The Capitol, the White House, and adjacent buildings

The South Portico of the White House.
Authenticated News International

underscores the purposes of L'Enfant is the charming, essentially modest White House, which has been judged by many as among the finest and most appropriate residences of state in the world.

The largest complex of public buildings that joins the Capitol to the White House is the Federal Triangle, an imposing facade of buildings that fronts on Constitution Avenue along the Mall and houses various federal departments and other activities of national importance. Other structures located along the Mall include the National Gallery of Art, the National Archives, the National Museum of Natural History, the National Museum of American History, and the National Air and Space Museum. Around the Capitol on Capitol Hill are the buildings of the Supreme Court, Library of Congress, and the various House and Senate office buildings.

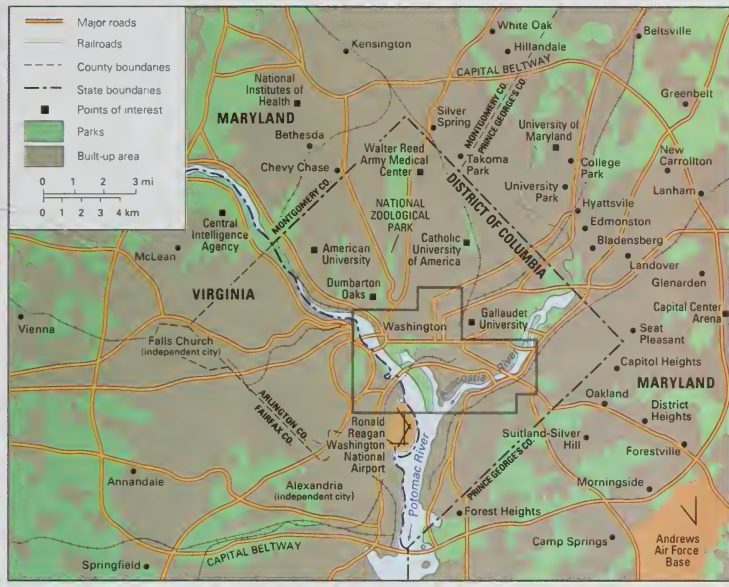
The increasing number of governmental departments and agencies has resulted in an explosion of construction, particularly along Independence Avenue and extending into southwestern Washington's Foggy Bottom area. These buildings have been designed without particular regard for their individuality: a series of shafts or cubes faced with granite or marble. To many people they seem to represent, in contrast to the earlier forms of governmental architecture, an honest but ugly reminder of the anonymous bureaucratic routines upon which so much of modern organizational life depends.

Ever since L'Enfant urged that Washington be lavishly **Statuary** equipped with "statues, columns or other ornaments" to **and** honour the nation's great, a continuous effort has been **memorial** made to assure that no open space in the city lacks its rep-**structures** resentative monument. Within the District of Columbia alone, more than 300 memorials and statues of varying size, purpose, and aesthetic merit have been raised—from the elegant and inspiring Lincoln and Jefferson memorials and the pure grandeur of the Washington Monument, to the statues of major and minor Civil War heroes, to memorial benches, Doric temples, and Japanese pagodas.

A growing concern that Washington would soon become a veritable quarry of stone and metal monuments dedicated to minor individuals and causes led to a movement toward "living" or "functional" memorials that attempt to translate the personality of the person being honoured. Within this context, the monument dedicated to Pres. John F. Kennedy was designed as a cultural centre for the performing arts. In addition, landscaping changes in the Mall area have removed most of the temporary buildings and returned the area to a purer interpretation of the L'Enfant design.

Attempts to bring Washington's waterways into an overall national capital plan have been relative failures. Important as were the Potomac and Anacostia rivers in the decision about the capital's location, neither has lived up to its anticipated potentiality in the commercial or cultural life of the city. Technology rendered them obsolete for transportation, while pollution limited their usefulness for recreation. Some modest progress, however, has been made to enhance their aesthetic and recreational possibilities.

Modern features. Washington as a city has expanded its influence and functions well beyond the 1790 boundaries established for the District of Columbia. Like the other large cities and metropolitan areas of the East Coast, it is beset with extreme social and economic problems. Unlike others, however, its surrounding suburban sprawl is part of other sovereign states, and the District can exercise little political control beyond its borders.

The strain of this growing area, which in large part reflects the increasing size and influence of the federal government, is playing an enormous part in the changing physical character of the central city. Plans to further develop Washington include greater dispersal of federal activities and installations to suburban locations to alleviate transportation problems. Such a movement has been in progress for some time, along with the decentralization of many business and commercial functions. The result of these movements has been to concentrate within the physical boundaries of the city only those monumental, cultural, and governmental structures that logically and historically can be located nowhere else.


The trends in planning that are changing the physical **Changes** character of contemporary Washington are of two basic **in the face** types. First, there has been an increasing effort to coor- **of** dinate and enhance those monumental aspects of the city **Washing-** that are the outstanding physical features and most mean- **ton** ingful to the nation itself—notably in the Mall and Capitol areas. With this trend is the design of new public buildings to operate efficiently and yet blend harmoniously with the older federal architecture. Examples of such newer structures include the East Building of the National Gallery of Art, which employs the so-called L'Enfant Angle in its architectural design, and the congressional office buildings on Capitol Hill.

Second, there have been efforts to make downtown com-

mercial activities more attractive, as well as more accessible. Several pedestrian malls have been constructed in the major downtown shopping area, and a new business and commercial complex, L'Enfant Plaza, has been established within walking distance of a number of the newest public buildings. A large convention centre was built, and a subway system, the Metro, was inaugurated. (Ri.W.S.)

Other new features since the city began more rapid changes during the 1970s include the renovation of Pennsylvania Avenue, the renovation of Union Station as the National Visitor Center, and the redesigning of Lafayette Square facing the White House, a move that was hotly debated because it involved the razing of a number of fine old buildings. The Vietnam Veterans Memorial, in West Potomac Park, was dedicated in 1982; two years later the Three Servicemen Statue was unveiled beside it, and in 1993 another statue, the Vietnam Women's Memorial, was completed nearby. The Korean War Veterans Memorial was dedicated in 1995, followed by the Franklin Delano Roosevelt Memorial in 1997. Major restoration of the Washington Monument was completed in 2001.

THE PEOPLE

The ethnic composition of Washington's population is about three-fifths African American and less than one-third white, with the remaining tenth a mixture of Asians, Africans, Latin Americans, and other ethnic minorities, including embassy personnel. In contrast, the suburban population is predominately white, with a sizable African American minority.

If any section of the country is overrepresented among Washingtonians, it is the Southeast and the nearby border states. John F. Kennedy once dryly remarked that "Washington is a city of Southern efficiency and Northern charm"; indeed, life in the city often has been described as more Southern and leisurely than Northern and fast-paced—a comparison that sometimes leads to conjectures about how the choice of Washington's site may have affected the functions of the national government throughout its history.

Changes in national administration bring about few real changes in the city's makeup. If the city has any true social aristocracy (aside from the upper echelons of the administration in power, members of Congress, and other high-ranking government officials), it is composed of a small cadre of well-to-do individuals or families who once held some office, found the capital's life congenial, and remained as permanent residents.

Partially because of its ethnic and socioeconomic makeup, the District of Columbia and its surrounding metropolitan counties present a distinctive pattern of population distribution and thus a variability in the city's neighbourhood characteristics.

Generally, within the northwestern area of the city and the suburban triangle of Maryland—including such unincorporated communities as Chevy Chase, Bethesda, and Silver Spring—that flanks this part of the city are located the majority of white middle-class and upper middle-class residents. In the west, overlooking the Potomac, is the oldest neighbourhood, Georgetown, which remains Washington's most exclusive and picturesque residential area. Within these neighbourhoods, extending eastward in the District to Connecticut Avenue and 16th Street, are located nearly all of the foreign embassies, the great churches, private country clubs, and housing that ranges from the moderately affluent to the luxurious.

East of 16th Street and extending north into the Maryland suburbs is the heart of the Washington African American community. The area illustrates the considerable diversity in quality of living available to Washington's residents: from tree-shaded, upper middle-class streets in the vicinity of Howard University to rows of deteriorating houses and subsidized housing complexes.

The southern sections of the city form rather distinct areas, determined partly by geographical features and partly by the socioeconomic character of the residents. The first area, which is actually beyond the District's boundaries, comprises the southwestern bank of the Potomac, which is crossed by six bridges joining the District and Virginia. In general this area is nonresidential, but it includes some of the city's more renowned landmarks, including the Pentagon and Arlington National Cemetery. The second area is an irregular triangle formed by the Potomac and Anacostia rivers, which converge at the apex of the triangle. Within this section are located a concentration of modern governmental buildings—Ft. Lesley J. McNair and the National Defense University—and the large recreational complex of East Potomac Park (known popularly as Hains Point). Urban renewal projects in this section have changed the residency pattern from slums to upper middle-class apartment and townhouse buildings. Many of the African American residents displaced by the

Kelly–Mooney Photography/Corbis

Georgetown, a residential section of Northwest Washington, whose 18th- and early 19th-century architectural design has been preserved by Congressional legislation.

southwestern renewal plans have shifted to already over-crowded northeastern parts of the District or have concentrated on the southeastern bank of the Anacostia River. This triangular-shaped, low-income area makes up the southeastern edge of the District and extends into Prince George's county, Maryland. (Ri.W.S./Ed.)

THE ECONOMY

Few cities in the United States are so dominated by the nature of their economic base as is Washington. Only two major economic activities provide virtually all of the income to the city and its residents. The federal civil service is by far the largest single employer in the metropolitan area. Tourism, which includes its retail trade and related services, is second in economic importance. Manufacturing and other commercial activities occupy only a minor place in the economic structure.

Economic dominance of government and tourism

Government. The federal government's dominance in establishing the character of economic and social life in Washington can scarcely be overestimated. Although the federal government itself employs a large number of residents of the metropolitan area, the vast majority of employed people are engaged in activities that support or depend on governmental programs or organizations of national or international scope.

Since the mid-20th century Washington has been transformed from a "federal town" to an information and communication centre that is competitive with the largest urban areas in the United States. In addition, it has become the coordinating centre for major foreign activities. As federal involvement has proliferated in both private and public sectors and both at home and abroad, there has been a steady trend toward relocating the offices of national associations from cities such as New York and Chicago to the Washington metropolitan area. There are more headquarters of national trade and professional organizations and associations in Washington than in any other area of the country. The presence of international organizations such as the World Bank and the International Monetary Fund has increased Washington's importance as one of the principal centres for coordinating aid, trade, and finance on the international level.

The District of Columbia, however, has a large population living at considerably lower socioeconomic levels. These residents also depend on the opportunities offered for federal employment but generally lack the educational qualifications for jobs at higher incomes. This factor, plus the minimal local control over the city's revenue system, the lack of significant taxable industry, and the tax-exempt status of the great majority of its real estate, forces the city to depend heavily on intergovernmental revenue and aid, that in effect, constitute payment by the federal government in lieu of the taxes it would pay if it were a private industry.

Tourism. Because it is the seat of the national government and the site of many of the nation's most significant monuments, Washington's second largest source of income derives from the millions of tourists who visit the city each year. The peak of the tourist influx occurs in the spring and summer months, but the capital city is basically a year-round attraction. In addition, Washington has become increasingly popular as a site for the annual conventions of national organizations and professional associations, most of which, as noted above, maintain a headquarters or branch office in the city. The business community, through such groups as the Metropolitan Washington Board of Trade and with the assistance of the federal government, has organized an increasing number of activities and facilities to make Washington more attractive to its visitors.

Transportation. Prior to the 1970s, various characteristics of the Washington area affected the nature and quality of its transportation networks. First, the L'Enfant plan covered only a small part of the present District of Columbia, excluding completely what has become the suburban area. Although many major radial avenues were extended to and beyond the District's borders, the street patterns outside the original city of 1791 were irregular at best. Second, Washington was a funnel for

north-south traffic along the East Coast until the mid-20th century. In addition, the Potomac and Anacostia rivers always formed barriers to traffic flow between the city and points south. Finally, although it has long been a city of white-collar commuters whose work draws them into the city, the District had barely minimal mass-transit facilities from suburban areas, necessitating nearly total reliance on the automobile.

Since the 1970s modern beltways and freeways have been built to facilitate the flow of traffic around and into the city, and a number of bridges now span the Potomac and Anacostia rivers. A major stimulus to the city's development was the opening of a subway system. The subway and extended rail and bus service are part of the city's modern mass-transit system, operated by the Washington Metropolitan Area Transit Authority. The authority also serves the neighbouring suburbs in Maryland and Virginia.

ADMINISTRATIVE AND SOCIAL CONDITIONS

Government. The city of Washington, as the site of the nation's capital, has evolved a governmental structure that is unique among U.S. cities.

Changing municipal forms. The first government of the city of Washington, established in 1802, comprised a mayor appointed by the president of the United States and a city council elected by the people. The city's character was amended in 1812 to provide for an elected board of aldermen, which, along with the council, elected the mayor. In 1820 Congress permitted the residents to elect both mayor and council. Since Article 1 of the U.S. Constitution empowers Congress to exercise exclusive legislation over the seat of government, however, the powers of the mayor and the council were limited, and their administration of the city was generally ineffectual.

In 1871 Congress created a territorial form of government for the District. The officials, all appointed by the president, included a governor, a board of public works, and a legislative assembly comprising an 11-member Council and a 22-member House of Delegates. In addition, the District was permitted a popularly elected, nonvoting delegate to the House of Representatives. This arrangement was abandoned after only three years following a series of financial crises that aroused opposition among both politicians and taxpayers. Congress resumed direct control of the city, providing administration by three commissioners appointed by the president. No provision was made for the franchise under the commissioner form of government, and residents of the District were denied all rights to vote until 1961. The 23rd Amendment to the Constitution then allowed qualified voters to vote in presidential elections but failed to permit participation in elections for local officials, all of whom continued to be appointed.

Evolution of District government

The issue of home rule for the residents of the District became increasingly prominent in the 1960s, and it was not unrelated to the general struggle for civil rights that characterized the nation as a whole. The most serious criticism of the commissioner form of government was that all legislation affecting it had to be passed by Congress: the House District of Columbia Committee and the Senate Governmental Affairs Committee were required to initiate all legislation pertaining to the District. Since the members of these committees were not permanent residents of Washington and represented constituencies that had little or no interest in the problems of the city, the responsiveness of Congress was felt by many to be slow or entirely lacking. Efforts on the part of various local groups over the years to achieve some degree of home rule were consistently blocked by the House committee, although the Senate committee passed five such bills between 1951 and 1963. It was often pointed out that the committees tended to be dominated by Southern congressmen who resisted efforts to give the franchise and other powers to the District because of its increasing black majority.

In 1967 Congress reorganized the District's government, abolishing the three-commissioner system and creating in its place a single commissioner (who assumed the title of mayor), an assistant commissioner, and a nine-member city council, all appointed by the president. The city

council was given authority to exercise certain legislative and regulatory powers once vested in the three commissioners, but such actions were subject to the veto of the mayor. In 1970 Congress created again the position of a nonvoting delegate to the House of Representatives, elected by residents of the District.

Movement toward home rule has continued. In 1973, under Pres. Richard M. Nixon, the limited Home Rule Act of 1964 was amended, providing for the popular election every four years of the mayor and city council members. In addition, the city council was expanded to 13 members. The mayor was given broader reorganizational and appointive authority. The city council was empowered to establish and set tax rates and fees, make changes in the budget, and organize or abolish any agency of government of the District. Congress, in turn, reserved the power to veto any actions of the District government that threaten the "federal interest." Thus, while the District has a recognizable municipal form of government, Congress continues to treat it in some respects as a branch of the federal government. The city's "district attorney" is the U.S. attorney for the District of Columbia, appointed by the president. The budget, passed by the city council and approved by the mayor, is reviewed and enacted by Congress. Moreover, Congress retains the right to enact legislation on any subject for the District, whether within or outside of the scope of power delegated to the city council.

Administration of municipal services. As under previous forms of government, municipal functions remain in control of a combination of local and federal committees. School-board members, formerly appointed by the U.S. District Court for the District of Columbia, became popularly elected in 1968. Public utilities are under a Public Service Commission appointed by the president. The zoning of private property is handled by the Zoning Commission, consisting of the mayor, the chairman of the city council, the Architect of the Capitol, and the director of the National Park Service. The water supply is under the jurisdiction of an Army engineer, given the title of District Engineer, but its distribution is controlled by the mayor. The National Park Service supervises the public parks of the city.

Overlapping federal and District responsibilities

Public security and law enforcement are handled by several separate law-enforcement agencies, each with its own jurisdictional area. Under the mayor is the Metropolitan Police Department, which has the responsibility for enforcing the laws and ordinances of the municipal government. The Capitol Police are responsible for the security of the Capitol building and its grounds. The Secret Service protects the White House and the president, while the National Park Police are responsible for all public parks and many recreational facilities.

Court system. The unwieldiness of Washington's governmental apparatus has long been most apparent in the operation of its courts. Until the early 1970s legal jurisdiction over District matters was shared by two federal courts and three local courts, appeals from which were directed to separate appeals courts. The Court Reorganization Plan was implemented in 1970 to reduce the confusion and inefficiency of this judiciary system.

Under the plan a single trial court, the Superior Court of the District of Columbia, was established to assume the functions of all the former federal and local courts. A single appeals court, the U.S. Court of Appeals for the District of Columbia, was established to function in a manner similar to a state supreme court. For the first time in its history, Washington had an integrated court system similar to the systems in all of the states.

Employment. Washington's commuters generally live outside the District of Columbia and represent a workforce that is highly specialized, professionally skilled, and well above the national averages in educational level and per capita income. Among the residents of the city of Washington, where a majority of the residents are African American, the unemployment rate, especially among youth, ranges well above the national average. Educational level and per capita income are considerably below the averages found in the surrounding suburbs. Nothing expresses the dilemma of the "two" Washingtons more clearly than the characteristics and location of its labour force.

Housing. In spite of the fact that the Washington metropolitan area has experienced a decline in its rate of population growth (with an absolute decline in the District of Columbia), the demand for housing has remained high. This demand was generated by a high rate of household formation, primarily among young adults (mostly affluent, one-family or single householders) from the post-World War II "baby boom" generation. Competition for existing housing resources has intensified between new householders and existing occupants. This has stimulated not only the conversion of rental apartments to condominiums but also the renovation of many single-family dwellings formerly occupied by lower income renters. While this gentrification process has resulted in the upgrading of a number of residential areas in the District, it has aggravated the problems of household displacement, primarily among lower income families, and has increased the pressure on the older, inner suburbs of the metropolitan area.   (Ri.W.S.)

Education. The public school system in Washington radically changed after the U.S. Supreme Court ruling in 1954 that declared racial segregation of public schools to be unconstitutional. Instead of reducing prejudice, however, the ruling increased the fears of many

View of Washington, D.C., including (from upper left) the United States Capitol, Washington Monument, Lincoln Memorial, Jefferson Memorial, and Potomac River. Theodore Roosevelt Island is in the foreground.

middle-class white families and led to their flight from central Washington to the suburbs. Many of the whites who remained in the city enrolled their children in private schools, which led to a serious racial imbalance in the public educational system. Nevertheless, the newly integrated schools did improve educational opportunities for African American students.

Despite the school system's many problems, Washington schools have had some success. The Duke Ellington School of the Arts, which opened in 1974 for talented high school students across the city, required applicants to demonstrate their artistic abilities before they could be considered for acceptance. Several other high schools that offer magnet academic programs and require students to apply for admission have proved to be successful in motivating students to pursue higher education.

Several institutions of higher learning offering undergraduate and graduate programs are located in the metropolitan area. Georgetown University, founded in 1789 as a seminary, is the area's oldest. The Catholic University of America (1889) makes Washington a centre of Roman Catholic education. The George Washington University, chartered as Columbian College in 1821, and American University, chartered in 1893, have become large, diversified universities. Howard University, chartered in 1867 and a traditionally black institution, offers a wide variety of graduate and professional programs and is supported largely by federal appropriations. Gallaudet University (1857), for the education of the deaf, receives both private and federal support. The University of the District of Columbia was created in 1977. The University of Maryland, George Mason College, and the Northern Virginia Campus of the University of Virginia are located in suburban areas.

In addition, numerous federal and privately funded institutions and associations produce a variety of both statistical and scholarly materials. The Brookings Institution is a nationally recognized centre for research in politics and economics; and the jointly administered National Academy of Sciences, National Academy of Engineering, Institute of Medicine, and National Research Council are staffed by many of the most eminent scientists in the nation. The National Institutes of Health offer both a centre and funding for basic and applied research in wide areas of medicine and mental health.

CULTURAL LIFE

Until the end of World War II, Washington was literally outside the main centres of American arts and letters, and the original plan for the city to become a focus of national culture was far short of realization. Its institutions of higher education were uniformly small, poor, and struggling; it had no significant collections of art; its facilities for the performing arts were either too small, inconveniently located, or nonexistent; and the only truly national museum, the Smithsonian Institution, was laughingly characterized as "the nation's junk closet."

In early descriptive guides to the city, the section on cultural facilities was devoted largely to the number and variety of churches, which were distinguished mostly for the presidents of the United States who had attended them. Practically alone on the scene was the magnificent Library of Congress, with the largest collection of books, maps, newspapers, documents, and manuscripts in the world. Since then, however, the development of cultural and recreational facilities in Washington has been one of the city's—and the nation's—proudest achievements.

The arts. Since its opening in 1941, the National Gallery of Art has become recognized internationally as one of the world's major art collections. Together with the Corcoran Gallery of Art, the Phillips Collection, the Freer Gallery of Art, the National Portrait Gallery, the National Museum of American Art, and the National Museum of African Art, and the Arthur M. Sackler Gallery, the capital city has achieved a position of eminence in the art world.

Washington's Arena Stage has been recognized since its founding in 1950 as one of the leading regional theatre companies in the nation, both for the excellence of its productions and for its leadership in seeking out new playwrights. The National Symphony Orchestra has achieved national acclaim. Aside from these features, the performing arts in the city comprised little more than road shows from New York City or pre-Broadway tryouts until the opening in 1971 of the John F. Kennedy Center for the Performing Arts, with its three theatres for music, opera, and drama and its two smaller theatres. The restored Ford's Theatre, the scene of the assassination of Pres. Abraham Lincoln in 1865, offers Washingtonians a unique opportunity to enjoy programs of cultural value in a setting of historical significance.

Architectural Washington holds interest outside its monumental areas. Prominent examples include the many fine 19th-century mansions, many of which are occupied by foreign embassies, along Massachusetts Avenue and in the area around Dupont Circle. Numerous homes in the Georgetown area, similarly renewed beginning in the 1930s, offer fine examples of the American Federal style of architecture dating from the early years of the nation. A stunning example of landscape architecture including formal gardens and a bird sanctuary, as well as a museum and research library of medieval art, is on display at Dumbarton Oaks.

National collections. Several Smithsonian Institution museums are located on the Mall. In 1855 the Smithsonian completed a red sandstone "castle" that housed offices, laboratories, a library, art and artifact displays, and living space for visiting scientists; today the castle serves as a visitors' centre. The Smithsonian Arts and Industries Museum (1881) was built of red and polychrome brick to exhibit the expanding museum collection. In 1910 the neoclassical, gray-granite and green-domed Natural History Museum was opened, where the famous Hope Diamond was later displayed. In 1923 the Freer Gallery, a Beaux-Arts style "treasure house," began to exhibit Charles Lang Freer's outstanding collection of Asian and 19th-century American art. The pink-granite, boxlike National Museum of American History has safeguarded the nation's scientific, technological, and historical treasures since 1964. Two major Smithsonian venues were added in the 1970s: the Hirshhorn Museum and Sculpture Garden, which displays philanthropist Joseph Hirshhorn's enormous collection of contemporary art; and, just to the east, the National Air and Space Museum, with an array of missiles, spacecraft, and airplanes, including the Wright brothers' flyer. In the 1980s two Smithsonian museums were built largely underground: the National Museum of African Art and the Arthur M. Sackler Gallery, which exhibits Asian art. The collections of the National Gallery of Art are housed in two buildings: an older, classical West Wing designed by John Russell Pope, and a newer, angular East Wing designed by I.M. Pei. The nearby National Archives, with its thorough collection of documents from American history (notably the Declaration of Independence and the U.S. Constitution), supplements the riches of the Library of Congress. Just south of the Mall is the United States Holocaust Memorial Museum (opened 1993).

Festivals. The traditional Cherry Blossom Festival held early each spring is the oldest of Washington's celebrations that combine the efforts of federal, civic, and commercial personnel. In spite of their attraction for tourists, the festival parade and crowning of a queen tend to be less important for Washingtonians than is the explosion of blossoms around the Tidal Basin and the Jefferson Memorial that the festival marks.

Also popular is Washington's annual festival of American folk arts and crafts, held for a week each summer on the Mall. This open-air display of the arts and crafts of many regional and ethnic subcultures has become an increasingly significant cultural event.

Recreation. Much of Washington's elaborate system of public parks and other open spaces was designed to heighten the visual impression of the federal buildings, but they have been applied increasingly to recreational purpose. The original L'Enfant plan set aside 17 areas for parks, including the Mall, the Washington Monument grounds, the Capitol Hill grounds, the White

Major art collections (margin note)

Smithsonian Institution (margin note)

House grounds (including the present Lafayette Square), and the small plots of greenery at the intersections of the major avenues. The preservation of these areas and the addition of others provides Washington with several hundred parks and green spaces.

In 1890 the city acquired Rock Creek Park, one of the largest natural parks within the boundaries of any city in the world. It comprises 1,754 acres (710 hectares) of virgin woodland forming the mile-wide valley of Rock Creek, which traverses the northwestern quarter of the city from suburban Silver Spring to the Potomac and is extensively developed for recreational uses. Within its boundaries is the National Zoological Park, occupying picturesque wooded hills and grassy meadows. Also within Rock Creek Park is the Carter Barron Amphitheater, where musical programs are presented in a wooded setting during the summer. Nature walks, horse trails, picnic areas, and sports facilities are spread throughout the park.

For 15 miles, from Georgetown to the Great Falls of the Potomac River (the shores of which have been protected from uncontrolled development on both the Virginia and District sides), stretches the historic Chesapeake and Ohio Canal, the original project of George Washington, which has been restored and declared a national monument. The towpath beside the canal is available for hiking and bicycling, and regularly scheduled trips are enjoyed by visitors in reconstructed, mule-drawn canal boats. On the Virginia shore is the scenic George Washington Memorial Parkway, from which motorists may enjoy a nearly uninterrupted view of the Potomac from above the northwestern boundary of the District to Mount Vernon, the home of Washington, below Alexandria. Between Georgetown and the Virginia shore lies Theodore Roosevelt Island, once a private plantation but now a nature sanctuary. The island is used as a wilderness strolling place for Washingtonians seeking relief from the city and offers one of the area's most tranquil and beautiful natural settings.

History

The idea of a national capital city seems to have originated at a meeting of the Congress in June 1783 in the Old City Hall in Philadelphia. The War of Independence had but recently been concluded, the treasury was empty, the nation had no credit, and it was heavily in debt to its soldiers for back pay. There was no president, and, though the 13 colonies were free, they remained a gathering of semi-independent sovereignties with divergent interests. On June 20 a large body of unpaid soldiers invaded Philadelphia to present their grievances to Congress.

Conception, siting, and design. No actual violence occurred, but a number of congressmen started a movement to establish a federal city where the lawmakers could conduct the business of government without fear of intimidation. Several locations were considered over the next six years, but Northern and Southern disagreements prevented decision until 1790.

Although the decision to locate the capital on the Potomac was largely a political compromise, selection of the exact site for the city was left to the newly elected president, George Washington. The chosen district, or territory as it was first called, was 10 miles on a side (100 square miles). Georgetown to the north and Alexandria to the south were both in the original district, while a third village, Hamburg, lay by the riverfront swamps in a part of Washington known traditionally as Foggy Bottom.

Important to Washington in his selection was the site's commercial potential. The river was navigable to Georgetown, an important tobacco market. The construction of a canal from there across the Cumberland Gap to the "western frontier" would tap the produce of the vast country beyond that was being opened to settlement.

While in Philadelphia, Washington negotiated with Pierre-Charles L'Enfant to lay out a plan for the new city. Apparently sensing the historic significance of his

Rock Creek Park, Washington, D.C.
Kelly-Mooney Photography/Corbis

appointment, L'Enfant conceived his plan on a grand scale. The Capitol's cornerstone was laid by Washington in September 1793, and construction was begun on the White House, designed by an Irishman, James Hoban, and on a modest cluster of nearby office buildings to house governmental departments. In October 1800 the archives, general offices, and officials of the government were moved to Washington from Philadelphia. Pres. John Adams took up residence in the White House, and the Congress met for the first time in the newly completed Senate wing of the Capitol.

The young city. Descriptions of life in early Washington reveal many of the shortcomings resulting from establishment of a capital city by fiat amid what was essentially a wilderness. What was conceived as a "city of magnificent distances" or, in Washington's words, "the Emporium of the West" was referred to by various statesmen and congressmen as "wilderness city," "Capital of Miserable Huts," "A Mud-hole Equal to the Great Serbonian Bog," and similar epithets. By the close of Thomas Jefferson's term of office in 1808, the population was scarcely 5,000. Until the introduction of the steam engine and the telegraph, a more or less continuous agitation went on in Congress and in the national press to move the capital because of its remoteness and inaccessibility.

In 1814 the capital was temporarily abandoned as the result of the invasion by a British force under Admiral Sir George Cockburn, who ordered the burning of the Capitol, the White House, and the Navy Arsenal. Although this action was rather inconsequential to the outcome of the War of 1812, it had the effect of solidifying Washington in the minds of many Americans as the national capital. Public indignation over destruction of the seat of government ended all significant movements to relocate the federal city. By the outbreak of the Civil War in 1861, the intensity of its image was firmly established. The course of that conflict was deeply affected by the actions of the federal government to defend Washington at all costs from nearby Confederate forces,

ment of
identity
as the
national
capital

who often threatened the city from two or more sides. If the Civil War completed the historical process that changed a loose confederation of states into a united republic, it also solidified the identity of Washington as the capital of the United States.

EVOLUTION OF THE MODERN CITY

Originally, the city of Washington and the District of Columbia were not coextensive, either geographically or administratively. The 10-mile-square district was reduced by about one-third in 1847 by the return of the land south of the Potomac to the state of Virginia. Alexandria city resumed its former independent existence, while Arlington county was created from the remainder. In 1895 Georgetown was annexed by Washington.

During and after the Civil War the District's population more than doubled within a few years, suddenly including 40,000 freed slaves who set a pattern of racial diversity that was to have a major impact on the city's life. The following century was filled also with physical and demographic growth and change within the city, with numerous political modifications attempting to harmonize the District's needs with its inherent status in relation to Congress, and with continuing activities to refine the cultural and monumental image of the city.

By the latter third of the 19th century the city had constructed an impressive number of monuments, but then and later many slums began to intrude on the city's image. Transformation of this and other problems was cut short by World Wars I and II but carried on after their conclusions.

During the 1930s thousands of workers moved to Washington to build the Supreme Court and office buildings such as those in the Federal Triangle. During World War II the city's population exploded, reaching about 950,000. National Airport and the Pentagon opened in 1941, the latter catering to 40,000 office and military personnel.

The latter part of the 20th century was marked by an exodus of the middle-class, both white and black, from the city. Many Washington neighbourhoods were swept away and replaced by huge, impersonal new federal agency buildings, and public housing complexes were erected in poor areas. However, communities across the city were partly successful in arresting highway construction through older neighbourhoods. In the 1960s an interest in historic preservation was reawakened, although race riots sowed fear and neglect in many neighbourhoods.

The construction of the Metro subway from the late-1970s helped renew interest in different parts of the city, and a real-estate boom in the 1980s revitalized many deteriorating areas, particularly the downtown, where urban life was brought full circle. Gentrification has proceeded since then. In the early 21st century Washington continued to struggle against crime and poverty, but its troubles were commensurate with those of other major urban centres, and for many residents, the city's cultural and economic benefits outweighed the negative aspects of urban life.

The capital has continued to develop according to the original tenets of L'Enfant's plan, with all of its later interpretations. In slightly more than two centuries Washington has changed from a small southern border town into an anchor in the line of major Northeast Corridor cities stretching northward to Boston. In addition, through its monuments and cultural institutions, the city continues to portray itself as the foremost symbol of American heritage and governance.   (Ri.W.S./Ed.)

Wellington

Arthur Wellesley, 1st duke of Wellington, twice reached the zenith of fame with a period of unexampled odium intervening. By defeating Napoleon at Waterloo he became the conqueror of the world's conqueror. After Waterloo he joined a repressive government, and later, as prime minister, he resisted pressure for constitutional reform. False pride, however, never prevented him from retreating either on the field or in Parliament, and for the country's sake he supported policies that he personally disapproved. In old age he was idolized as an incomparable public servant—the Great Duke. Reaction came after his death. He has been rated an overcautious general and, once, Britain's worst 19th-century prime minister. Today there is widespread appreciation of his military genius and of his character as an honest and selfless politician, uncorrupted by vast prestige.

Early life. Arthur Wesley (later, from 1798, Wellesley) was born on May 1, 1769, in Dublin, the fifth son of the 1st earl of Mornington. Too withdrawn to benefit from his Eton schooling, he was sent to a military academy in France, being, in his widowed mother's words, "food for powder and nothing more." At the age of 18 he was commissioned in the army and appointed aide-de-camp to the Irish viceroy. In 1790–97 he held the family seat of Trim in the Irish Parliament. At 24, though in debt, he proposed to Catherine (Kitty) Pakenham but was rejected. Arthur abandoned heavy gambling to concentrate on his profession. As lieutenant colonel of the 33rd Foot by purchase, he saw active service in Flanders (1794–95), learning from his superiors' blunders. After failing to obtain civil employment, he was glad to be posted to India in 1796.

Service in India In India he adopted a regimen of abstemiousness and good humour. The arrival of his eldest brother, Richard, as viceroy enabled him to exploit his talents. He commanded a division against Tipu Sultan of Mysore and became governor of Mysore (1799) and commander in chief against the Marāthās. Victories, especially at Assaye (1803), resulted in a peace that he himself negotiated. All the successful qualities he later exhibited on European battlefields were developed in India: decision, common sense, and attention to detail; care of his soldiers and their supplies; and good relations with the civilian population.

Duke of Wellington, portrait by Francisco de Goya, 1812.
In the National Gallery, London.

Napoleon was unwise in later writing him off as a mere "Sepoy general." Wellesley returned to England in 1805 with a knighthood.

Wellesley's new assignments were disappointing: an abortive expedition to Hanover, followed by a brigade at Hastings. But he felt he must serve wherever duty required. One duty was to marry his faded Kitty in 1806; another was to enter Parliament in order to repel radical attacks on his brother's Indian record. He spent two years in Ireland as Tory chief secretary. On a brief military expedition to Copenhagen (1807), a welcome break, he defeated a small Danish force. When in 1808 the Portuguese rose against Napoleon, Wellesley was ordered to support them.

Victory in the Napoleonic Wars. Wellesley did not intend to be "half beaten before the battle began"—the usual effect on continental armies of Napoleon's supremacy. With "steady troops" he expected to master the French attack. His "thin red line" of British infantry did indeed defeat Gen. Andoche Junot's columns at Vimeiro (August 21), but the arrival of two superior British officers prevented a pursuit because they preferred to sign the unpopular convention of Sintra, whereby Junot's army was repatriated. Public outcry brought about the court-martial of Wellesley and his colleagues. Though acquitted, Wellesley returned to Ireland as chief secretary. After the British evacuated Spain, however, he persuaded the government to let him renew hostilities in 1809, arguing that Portugal could still be held, a decision that was crucial to Europe. Campaign in Portugal and Spain Landing at Lisbon, he surprised Marshal Nicolas-Jean de Dieu Soult, captured Oporto, and chased the French back into Spain; but a joint Anglo-Spanish advance on Madrid failed, despite a victory at Talavera (July 27–28). Though rewarded with a peerage for his offensive, Viscount Wellington retreated with his greatly outnumbered force to his Portuguese base, defeating Marshal André Masséna at Bussaco on the way (September 27, 1810). He had secretly fortified the famous "lines of Torres Vedras" across the Lisbon peninsula. Masséna's evacuation of Portugal in the spring of 1811 and the loss of Fuentes de Oñoro (May 3–5) triumphantly justified Wellington's defensive, scorched-earth policy and confirmed his soldiers' trust in him. He was nicknamed "nosey" by his men, and "the beau" by his officers, for his slim five feet nine inches, the perfectly cut civilian clothes he preferred to wear, his wavy brown hair, and brilliant blue eyes.

His slowly growing army was not strong enough to capture the Spanish fortresses of Ciudad-Rodrigo and Badajoz until 1812. Then, having defeated "40,000 Frenchmen in 40 minutes" at Salamanca (July 22), he entered Madrid (August 12). His siege of Burgos failed and his army retreated again to Portugal, from which it was launched for the last time into Spain in May 1813. After a dash across the peninsula, he brought the French to bay at Vitoria, routing them and capturing all their baggage (June 21). This glittering prize was too much for the victors, who let the French escape into the Pyrenees, while Wellington denounced his drunken troops as "the scum of the earth." The victory at Vitoria gave impetus to the European alliance against Napoleon, and Soult's initial success in the Pyrenees could not prevent Wellington from taking San Sebastián and Pamplona. Whey dry weather came, Wellington invaded France, crossing the river lines one after another until on April 10, 1814, he stormed into Toulouse, thus ending the Peninsular War. (Four days earlier Napoleon had abdicated.) Already marquess and field marshal, he was now created a duke, with the nation's gift of £500,000 and later of Stratfield Saye in Hampshire to keep up his position.

With Napoleon on Elba, Wellington was appointed ambassador to the restored Bourbon court of Louis XVIII. In February 1815 he took the place of Viscount Castlereagh,

the foreign secretary, at the Congress of Vienna, but, before delegates could finish their peacemaking, Napoleon had escaped, landing in France (March 1) to begin his Hundred Days. The victory of Wellington and the Prussian field marshal Gebhard Leberecht Blücher on June 18 at Waterloo established the Duke as Europe's most renowned—if not most jubilant—hero. "I hope to God that I have fought my last battle," he said, weeping for the fallen. "It is a bad thing to be always fighting." His hope was fulfilled. As commander in chief during the occupation of France, he opposed a punitive peace, organized loans to rescue French finances, and advised withdrawal of the occupying troops after three years. For these policies he won the gratitude of the peace congress, returning home in 1818 with the batons (symbol of field marshal) of six foreign countries.

Role in the cabinet. Wellington's experiences abroad prevented him from ever becoming a party politician. Though he joined the Earl of Liverpool's Tory cabinet as master general of the ordnance, he exempted himself from automatically opposing a subsequent Whig government: "a factious opposition," he argued, "is highly injurious to the interests of the country." His identification with the party of law and order, however, increased when postwar discontent boiled over in the Peterloo Massacre at a Manchester demonstration for parliamentary reform and the Cato Street Conspiracy, a plot to murder the Cabinet. The popular George Canning succeeded Viscount Castlereagh as foreign secretary in 1822. Despite Canning's antipathy to the congress system, Wellington himself overbore George IV's personal objections to him, believing that the system was by now unshakably established. When Canning extricated Britain from its European commitments, Wellington was left to bitter self-reproach. His own diplomatic failures at the Congress of Verona (1822), at which he vainly sought to heal dissension among the European allies, and in Russia (1826) increased his chagrin. Straightforward to a fault, Wellington was unsuited to carrying out Canning's subtle policies, but he gained respect abroad as an honest man.

In 1825 Wellington turned to Ireland's problem, formulating it as a basic dilemma: political violence would end only after the Catholics' claim to sit in Parliament, known as Catholic Emancipation, had been granted; yet the Protestant establishment, or ascendancy, must be preserved. He worked privately at a solution, by which a papal concordat to ensure at least minimum control of Catholic clergy would be the precondition of Emancipation. When Canning, an unqualified Emancipator, became prime minister in April 1827, however, Wellington felt that Protestant ascendancy was in jeopardy. He and Robert Peel headed a mass exodus from the government, Wellington also resigning his command of the army. This action was interpreted as pique at the King's choosing his rival for prime minister. In denying the allegation, Wellington rashly asserted that he, a soldier, would be "worse than mad" to consider himself fit for the premiership. After Canning's death that August, he resumed his army command. Within five months Canning's successor, Viscount Goderich, had given up the task, and on January 9, 1828, the King summoned the Duke of Wellington.

Years as prime minister. The Duke's aim was to achieve a strong and balanced government by reuniting the Tory Party. Having reluctantly resigned again as commander in chief, he invited the Canningites, headed by William Huskisson, to serve, while dropping the ultra-Tories as incompatible with his policy of moderation. With the right wing thus alienated, a chasm began to open on the left. The opposition's demand for extensive reforms met with sympathy from Huskisson's group. Wisely, the Duke retreated, first on a church issue, himself reforming the Test and Corporation Acts that penalized Nonconformists, and again on a Corn Law (prohibiting importation of cheaper foreign grains) question, introducing a more liberal reform than he and the agricultural interest desired. Shortly afterward, however, he collided head-on with the Huskissonites on parliamentary reform; the whole group resigned in May. A further crisis immediately arose during the by-election in Clare, Ireland, where William Vesey-Fitzgerald,

Huskisson's ministerial successor, defending his seat, was defeated by Daniel O'Connell, the Irish Catholic leader. The defeat of Vesey-Fitzgerald, a popular pro-Catholic, carried an alarming moral for the Duke: until Emancipation was granted, no Tory would win in southern Ireland. There might well be civil war. In August 1828 Wellington therefore undertook the most exacting political duty of his career—the conversion of George IV, Peel, who was now leader of the Commons, and a majority of Tories to Catholic Emancipation, a reform that they had hitherto regarded as anathema. It took six months of indefatigable persuasion behind closed doors to win over the King. Peel's position was equally problematic—as a publicly declared Protestant, he clung to the idea of supporting Emancipation only from the back benches; but finally Wellington's patience and Peel's generosity prevailed, and he agreed to continue leading the Commons. A number of ultra-Tories defied to the last Wellington's order to "right-about face," but the majority of the party obeyed. So in April 1829, though the Tories were split, Catholic Emancipation became law, the Duke's greatest political victory, with melodrama being added by his fighting a duel with an abusive ultra-Tory, the Earl of Winchilsea.

Wellington has sometimes been criticized for inconsistency. It now appears that he was merely secretive in not taking the public into his confidence much earlier. His willingness for some form of Emancipation by 1825 might with advantage have been disclosed.

A demand for further changes, already stimulated by Wellington's own achievements, was powerfully reinforced by countrywide hardship during 1829–30 and canalized by Charles Grey, the 2nd Earl Grey, the Whig leader, into fresh moves for parliamentary reform that would allow industrial towns like Birmingham to have a voice in Parliament, in place of pocket boroughs owned by the nobility and gentry. Expression of dissatisfaction with Wellington's fatalistic attitude toward poverty and unemployment was made possible when the accession of William IV in 1830, following George IV's death, provided a general election. France's bourgeois revolution that same year—the July Revolution—greatly encouraged British reformers. Though Wellington's ministry survived, it was weakened, and Huskisson's sudden death frustrated tentative plans for reconciliation. Wellington saw parliamentary reform not as a panacea but as constitutional suicide. A fortnight before the opening of Parliament he wrote a letter to a friend denouncing reform as ruinous and disclosing his unalterable decision to oppose it. He staggered Parliament on November 2 with an uncompromising declaration against any reform whatever. A combination of reformers and vengeful ultra-Tories defeated him on the 15th. Peel made him resign the next day. He was succeeded by Grey.

As a soldier Wellington had shown uncanny ability in guessing what lay "on the other side of the hill." Through lack of political imagination, however, he saw revolution beyond the hill of reform—"revolution by due course of law." For this delusion he was deservedly called reactionary.

Last years. In opposition, the Duke proceeded to thwart Grey's attempts to get a reform bill through the Lords. Wellington's windows were twice smashed by radical mobs, and his iron shutters helped form the image of an iron duke. The titanic struggle culminated in the crisis of May 1832, which promised to end like the July Revolution of France. The King refused to create enough new peers to overwhelm the hostile Lords, Grey resigned, and Wellington failed to recruit an alternative government. Faced by tumultuous deadlock, Wellington, still opposing reform, then retreated for the sake of the country, persuading his followers to join him in absenting himself from Parliament until the Reform Bill became law in June. He was mobbed nonetheless by an angry crowd on Waterloo Day. "An odd day to choose," was his only comment.

The Duke's abstention had saved the Lords, and, as long as he led the Tory peers, he continued to steer them away from fatal clashes with the Commons. Whenever possible he supported the King's government. In 1834 William IV dismissed the Whigs by a political coup, summoning the Duke to form a ministry; but the 65-year-old duke

replied that Peel must be prime minister. This abnegation, most rare in a politician, did not go unappreciated. He served under Peel as foreign secretary (1834–35) and as minister without portfolio (1841–46). He also served as chancellor of Oxford, constable of the Tower, lord-lieutenant of Hampshire, and elder brother and later master of Trinity House, not to mention Queen Victoria's father figure. He made a mistake in holding the chief command of the army throughout his last 10 years, because he was past initiating the reforms that were later sorely needed. Nevertheless, he showed a touch of his old genius in 1848, when his calm handling of a threatened Chartist rising prevented any violence. Thanks to his again ordering the peers to "right-about face," this time over the Corn Laws, he enabled Peel to abolish them. Wellington retired from public life after 1846, though he was still consulted by all parties. Apsley House, his town residence at Hyde Park Corner, was known as No. 1 London. As lord warden of the Cinque Ports, he died at Walmer Castle, his favourite residence, from a stroke on September 14, 1852. He was given a monumental state funeral, the last heraldic one in Great Britain, and was buried in St. Paul's Cathedral.

Personal life.   The phrase "retained servant of King and people" and variants of it were used repeatedly by the Duke of himself and aptly suggest the self-dedication for which he is chiefly honoured. Many amusing personal peculiarities in clothes and correspondence, together with a gift for repartee, made him a "character" as well as a hero. "Publish and be damned!" was his famous retort to a blackmailer. His marriage was not happy: Kitty both feared him and worshipped him to excess. She died on April 24, 1831. Of his two sons, the elder edited his latest *Despatches* and the younger produced the grandchildren to whom he was devoted, as he was to all children. His intense friendships with Harriet (the wife of Charles) Arbuthnot, Angela Georgina Burdett-Coutts, and others showed that he could have been happy with a clever woman; perhaps he was happiest of all, however, in the camaraderie of his staff—his military family. Some modern historians have objected to the posthumous title Iron Duke on the reasonable grounds that he was neither cold nor hardhearted. Yet he himself often boasted of his iron hand in maintaining discipline. His engaging simplicity and extraordinary lack of vanity were expressed in a favourite saying, "I am but a man."   (E.Lo.)

BIBLIOGRAPHY.   The *Wellington Dispatches*, published in three series, are essential source material: *Dispatches 1799–1818*, ed. by GURWOOD, 12 vol. (1834–38; Index, 1839); *Supplementary Despatches . . . 1794–1805*, 15 vol. (1858–72); and *Despatches, Correspondence, and Memoranda . . .*, new series, ed. by the 2nd DUKE OF WELLINGTON, 8 vol. (1867–80). See also *Wellington: Political Correspondence*, ed. by JOHN BROOKE and JULIA GANDY (begun in 1976, covering the years 1833–46). Two outstanding biographies are SIR HERBERT MAXWELL, *The Life of Wellington*, 2 vol. (1899–1900); and PHILIP GUEDALLA, *The Duke* (1931, reissued 1976), though they did not have the advantage of material later collected and edited by the 7th DUKE OF WELLINGTON: *The Journal of Mrs. Arbuthnot, 1820–1832*, 2 vol. (1950); *Wellington and His Friends* (1965), being selected letters to Mr. and Mrs. Arbuthnot and three other women; *A Selection from the Private Correspondence . . .* (1952); and *Conversations of the First Duke of Wellington with George William Chad* (1956), a slight but useful diary. GEORGE R. GLEIG, *The Life of Arthur Duke of Wellington* (1862), and *Personal Reminiscences* (1904), are comprehensive but inaccurate; MURIEL WELLESLEY, a relative, pays tribute in *The Man Wellington Through the Eyes of Those Who Knew Him* (1937) and in *Wellington in Civil Life* (1939). CHARLES CRUTTWELL, *Wellington* (1936); and FRANCIS J. HUDLESTON, *Warriors in Undress* (1925, reissued 1969), give unsympathetic pictures. Military studies and biographies include S.G.P. WARD, *Wellington's Headquarters* (1957); MICHAEL GLOVER, *Wellington As Military Commander* (1968), and *Wellington's Army in the Peninsula: 1808–1814* (1977; U.S. title, *The Army of the Duke of Wellington in the Peninsula*, 1977); JAC WELLER, *Wellington in the Peninsula, 1808–1814* (1962), *Wellington at Waterloo* (1967), and *Wellington in India* (1972); and SIR ARTHUR BRYANT, *The Great Duke* (1971). Large-scale biography is found in ELIZABETH LONGFORD, *Wellington: The Years of the Sword* (1969), and *The Pillar of State* (1972, both reissued in 1982). Of especial interest are the perceptive and scholarly essays in *Wellington Studies*, ed. by MICHAEL E. HOWARD (1959). Valuable reminiscences by men who knew and admired Wellington are PHILIP STANHOPE, *Notes of Conversations with the Duke of Wellington 1831–1851* (1938); and ELLESMERE, *Personal Reminiscences of the Duke of Wellington* (1903). Collections of anecdotes proliferated after his death, the best being SIR WILLIAM FRASER, *Words on Wellington* (1899).

The West Indies

The West Indies region includes all of the islands that extend through the Caribbean Sea from the tip of the Florida Peninsula to the northern coast of South America. They include 23 political entities, some of them quite small and relatively unknown to the outside world. The West Indies derives its coherence and distinctiveness from a combination of four factors, one geographic, the other three historical. The geographic feature is insularity, and the three historical themes are colonialism, the sugar plantation, and slavery.

The West Indies range in size from Cuba, with an area of 42,804 square miles (110,861 square kilometres) and more than 10 million inhabitants, down to the tiny, uninhabited rocky islets of the Grenadines and the Virgin Islands. Most of the islands are smaller than Barbados, which has an area of 166 square miles and a quarter of a million inhabitants. Their physical fragmentation and the small size of most islands prepared the West Indies for a long history of colonialism and external domination and dependency. Territorial partition of the West Indies among the Spanish, French, British, Dutch, and Danish brought heavy recurrent fighting to the region in the 17th and 18th centuries; colonial possessions were captured in time of war only to be traded through peace treaties in furtherance of the geopolitical ambitions of the imperial powers.

Colonial partition of the West Indies has had a number of important consequences. Interisland connections have remained weak, because each colonizing power tended to dominate relationships with its own colonies. Where interisland linkage has occurred, it has been confined largely to islands belonging to the same European language group (each of these usually being of the same colonial affiliation). Moreover, the method of decolonization has generally followed these same political-linguistic lines. A further differentiating factor stems from this linguistic fragmentation. The Hispanic islands have a double identity—West Indian (or Caribbean) but also Latin-American; this is lacking in the English-, French-, and Dutch-speaking territories, where identities are above all insular. (The term Latin America is, however, often used geographically to encompass all of the territory south of the United States to Antarctica.)

If colonialism has been effaced over time by decolonization—and some parts of the West Indies experienced almost 500 years of European imperialism—the dominating economic entity of sugar monoculture, too, has diminished in all but Cuba and Saint Kitts. The rise of West Indian peasantries after the 19th-century slave emancipation, and economic diversification into industry, tourism, mining, and oil and natural gas drilling in the 20th, have transformed the economic base in most societies, especially since World War II. Plantations continue to occupy vast tracts of land, but their social significance has declined as people have left the countryside, either moving to the towns or emigrating to other countries. Still, dependence on one or a few products is the major economic problem in most of the states.

The most blatant forms of racial discrimination built into West Indian systems of slavery began to disappear with emancipation more than a century and a half ago, and the process has been hastened by decolonization. Nevertheless, most West Indian societies remain stratified by colour, culture, and class, and even in postrevolutionary Cuba, which is predominantly a white society, blacks are notably absent from the revolutionary leadership, despite the official elimination of class and colour lines. In the English-, French-, and Dutch-speaking territories, decolonization has created a mulatto and black political elite, although its position has been challenged in Trinidad and Tobago, where the large East Indian population has for long been in opposition, having been included in a coalition government since 1986. Generally the black political elites, supported by white and mulatto commercial interests, have promoted a multiracial ethic, which in most instances accepts the social order. This has been less true of Jamaica in particular, where white emigration, a powerful and creative arts movement, and the entrenchment of nationalistic governments since 1972 have led to the elaboration of a strong, black national identity.

Despite the region's common historical background and insularity, little cohesiveness or unity has developed among the West Indian states. Divided linguistically and culturally, the West Indies can for practical purposes be categorized into four distinct groupings according to common historical and political backgrounds: a Hispanic group plus Haiti, with long histories of political dictatorship and recurrent U.S. intervention; the British West Indies—now usually called the Commonwealth Caribbean (which includes mainland Belize and Guyana) and united through various regional associations such as the Caribbean Community and Common Market (Caricom) and the Organization of Eastern Caribbean States (OECS); the French Antilles (Guadeloupe and Martinique), now politically incorporated with their dependencies into France proper as overseas *départements;* and the Netherlands Antilles, from which Aruba was constitutionally separated in 1986 pending a decision on independence. Haiti and the Dominican Republic have observer status at Caricom meetings, but Cuba's membership in the socialist, mostly eastern European economic group Council for Mutual Economic Assistance (Comecon) and Puerto Rico's quasi-colonial ties to the United States make Pan-West Indian economic and political cooperation a difficult realization. The one institution of which virtually all West Indian states are members is the regional meteorologic service: hurricanes ignore all distinctions of West Indian people.

This article is divided into the following sections:

THE REGION

Physical and human geography

THE LAND

Relief, drainage, and soils. The West Indian archipelago stretches for more than 2,000 miles (3,200 kilometres) from Cuba almost to the north coast of South America. This island chain, divided principally into the Greater and Lesser Antilles, separates the Caribbean Sea from the Atlantic Ocean. Other islands of the region are isolated groups on the continental fringe of the Antilles, including The Bahamas, Trinidad and Tobago, and the Netherlands Antilles. (Bermuda, although sometimes discussed with the region, is not physically related to the other islands.)

The shape and alignment of the Greater Antilles—Cuba, Jamaica, Hispaniola (Haiti and the Dominican Republic), and Puerto Rico (to which the Virgin Islands are structurally related)—are determined by an ancient chain of folded and faulted mountains that in Cretaceous times extended from Central America through the Caribbean. Remnants of this system occur in the Blue Mountains of Jamaica and in the Sierra de los Órganos and the Sierra Maestra in Cuba. Duarte Peak in the Dominican Republic, another component of this range, rises to some 10,400 feet (3,170 metres) and is the highest point in the Caribbean.

Geologic formation appears in margin next to paragraph above.

Each Greater Antillean island has an encircling coastal plain, backed on the north coast of Cuba, Jamaica, and Hispaniola by Pleistocene-raised shorelines that reach heights of 1,000 feet. Structural depressions separate the original mountain ranges from interior valleys, notably in the Enriquillo basin in the Dominican Republic, which is below sea level, and in the Cayman Trench between Cuba and Jamaica, where the depth exceeds 25,200 feet, the deepest point in the Caribbean Sea. The Caribbean is a physically volatile zone characterized by frequent seismic disturbances, some of them disastrous, as the devastating Jamaican earthquakes at Port Royal (1692) and Kingston (1907) and the eruption of Mount Pelée on Martinique will recall.

The Lesser Antilles begin east and south of the Virgin Islands and are composed of a double arc of small islands. (For practical purposes the Virgin Islands are included in this discussion of the Lesser Antilles.) Stretching from Saint Kitts to Grenada, the mountainous inner arc consists of volcanic cones, some still active. The outer arc—running from Anguilla to Barbados—is made up of low, flat islands, whose limestone surface overlies older volcanic or crystalline rocks. The Lesser Antilles are also often divided into a Leeward (northern) group and a Windward (southern) group.

On the continental fringes of the Greater and Lesser Antilles are located The Bahamas, Trinidad and Tobago, and numerous islands off the Venezuelan coast, including the southern Netherlands Antilles. The Bahamas are flat patches of porous limestone and coral; coral reefs also fringe many of the Greater Antilles. Trinidad's Northern Range is a continuation of the Andean system, as are the planated (flattened) islands north of Venezuela, but the southern plains of Trinidad are formed from deposition from the Orinoco River in Venezuela.

The drainage of the West Indies is characterized by short rivers, whose steep mountain courses, often across crystalline rocks, give way to sluggish channels on the coastal plains. The extensive dry season, which causes some of these rivers to dry up for part of the year, is notably intense on the southern, leeward coasts of the Greater Antilles. Irrigation must be used or deep wells dug in some of the drier areas. Also in the Greater Antilles the extensive limestone outcrops have given rise to a tropical karst landscape, which is characterized by the porosity of the rock and systems of underground drainage; the condition has created rounded, conical, or elongated hummocks (knolls) separated by depressions.

Rivers appears in margin next to paragraph above.

Topography and geology have been crucial to soil formation in the West Indies. In the mountains, especially in the Greater Antilles, the original forest cover supplied a high organic content to the surface layer. But deforestation has led to erosion and to the exposure of an infertile mountain soil, especially in Haiti and Jamaica. Soils of the limestone areas fall into two groups: terra rossa is a red bauxitic soil with substantial organic matter; rendzina suffers impeded drainage. Lowland soils occur on the coastal plains and in interior basins; they are the most fertile soils and, together with the volcanic soils of the Lesser Antilles, have been cultivated in sugarcane for more than 300 years, in many instances without loss of quality.

Climate. Most of the West Indies lies within the tropical zone astride the track of the northeast trade winds. The tropical maritime climate exhibits no summer or winter but rather a change from a wet to a somewhat drier season. Temperatures remain fairly constant throughout the year. At weather stations anywhere in the small islands and near the coasts of the larger ones, temperatures vary within a mean daily range of 10° to 15° F (6° to 8° C), fluctuating between the low 70s and mid-80s F (low 20s and upper 20s C) from December to April and between the mid-70s and upper 80s F from May to November. Inland in the Greater Antilles the cooling influence of the sea, and the sea breeze, is lost. Frost is unusual, even in the highest mountains, and extreme low temperatures rarely drop below 55° F (13° C). Relative humidity is high throughout the year, usually ranging between 65 and 85 percent.

Differences in size, shape, topography, and location in relation to the northeast trade winds influence the amount and seasonality of rainfall. Many stations in the Greater Antilles and Leeward Islands record 40 to 65 inches (1,016 to 1,651 millimetres) per year, with more than 200 inches (5,000 millimetres) on the highest peaks. There is, however, a marked rain-shadow effect on the Greater Antilles' southern coasts, which are distinctly arid, and Saint Martin and Anguilla have salt ponds and water cisterns. The entire Windward group is well watered; but to the south the rainfall diminishes, and Aruba and the Netherlands Antilles (Bonaire and Curaçao) at the southwestern extreme are desertic. Bonaire has one short wet season; Trinidad and Dominica have one wet and one dry season; the Greater Antilles have two wet and two dry seasons.

Robert Harding Picture Library

The coastal town of Soufrière, Saint Lucia, nestled in a valley near the Gros and Petit Pitons, two huge mounds of weathered volcanic rock. Volcanic activity is common to this part of the Caribbean.

Climatic influences originating outside the West Indies bring extreme conditions. Cold fronts extend south from the North American high-pressure anticyclone system from December to April, but these winds, which produce a sudden drop in temperature, overcast skies, and light rain, seldom blow south of Antigua. Severe tropical storms originating over the Atlantic occasionally become hurricanes. Skirting north of Trinidad and Tobago (although these have been hit occasionally), they usually sweep through the Lesser Antilles before swinging west across the Greater Antilles. Hurricanes are a source of great concern because of the damage they cause to houses, crops, animals, and human life, and the economy of a hard-hit island can require a year or more to recover.

Plant and animal life.   Relief and climate have a direct bearing on the natural vegetation of the West Indies, but the influence of human beings is also manifest. Clearing and burning the vegetation have transformed the plant geographies of all but the most isolated and inhospitable regions.

The original vegetation of the plains was a sparse forest of lignum vitae and ceiba (cotton) trees, but most of the lowland is now cultivated and supports imported food trees, such as breadfruit and mango, and floral species of great brilliance—royal poinciana (flamboyant tree), frangipani, bougainvillea, and hibiscus. Swamps, mangroves, and marsh woodlands occur along the coasts, but arid environments are characterized by thorn scrub, columnar cactus, or sparse, low forest. At heights above 1,000 feet the trees form a closed canopy and are covered with epiphytes, bromeliads, and tree ferns; in some places above 5,000 feet this mist forest gives way to elfin woodland and alpine grass.

West Indian fauna is an impoverished version of the fauna in the place from which much of it was derived—South America. Only Trinidad, adjacent to Venezuela, has a wide range of mammals—sloths, anteaters, raccoons, howler monkeys, and bats. Reptiles are more diverse because of their ability to cross water, and the islands generally abound with lizards, caimans, crocodiles, and snakes. Above all, the West Indies display a rich variety of native birds—hummingbirds, pigeons, doves, and parrots being ubiquitous, with flamingos, ibis, and mockingbirds having a more restricted distribution.

In prehistoric times the most abundant faunal habitats were the forest canopies—with varieties of birds, bats, and insects—and the sea margins, which were rich in turtles, clams, oysters, caimans, manatees, dolphins, red snapper, bonito, and flying fish. These are still the main habitats of the species, but environmental destruction by humans or human-introduced predators, such as the African green monkey, the mongoose, and some rat species, has led to rapid species extinction, especially in the 20th century. Some nonextant species include the herbivorous tortoise, the rock iguana, and the giant barn owl.

Settlement patterns.   West Indian islands have been intensively settled since the 17th century, when sugar plantations were introduced to the British and French colonies. The 19th century witnessed slave emancipation and the creation of free peasantries, while the 20th century has been characterized by shifts in population to the cities and towns. The capitals of the Greater and Lesser Antilles are all major ports and the sites of much of the urban migration that has developed since the mid-20th century. Havana, Cuba, and Santo Domingo, Dom. Rep., are cities of more than two million and 1.8 million, respectively. San Juan, P.R., and Port-au-Prince, Haiti, have more than 400,000 inhabitants each. Other relatively large cities of the region include Willemstad, Netherlands Antilles, Kingston, Jam., and Fort-de-France, Martinique.

THE PEOPLE

Ethnic composition.   The numbers of white and black West Indians are about equal, and only a slightly smaller percentage is mulatto, who form a distinct colour category. Many West Indian countries have large black majorities, but whites account for some 70 percent of the population of Cuba and Puerto Rico, which between them have more than 40 percent of the total West Indian population. Else-

where, except for the Dominican Republic, where mulattoes form about three-fourths of the population, and some small dependencies, blacks are the largest single element but not necessarily the majority. Haiti and Jamaica have the largest numbers of black population.

Race, colour, culture, ethnicity, and class are intertwined in complex ways in Caribbean societies, but they may be categorized into four different social types: (1) folk societies that are characteristic of small (less than 20,000 population) islands or combinations of islands, lacking class stratification and ethnic diversity, and containing one or more colour groupings, (2) stratified societies that exist where there is a close association between colour, class, and culture, as in Jamaica, Haiti, and the Windward and Leeward Islands, all of which were slave societies in the 17th and 18th centuries, (3) societies in which race salience is of prime importance, as in Trinidad and Tobago, where the black, brown, and white stratification has been confronted by a large, segmented East Indian population, and (4) class-stratified societies that have nonblack majorities—such as predominantly white Cuba and Puerto Rico and the predominantly mulatto Dominican Republic, which developed as sugar producers in the 19th century and where blacks and black culture are now confined largely to enclaves in the stratification.

Linguistic composition.   The West Indies are linguistically diverse. In addition to the languages of the colonial powers—English, Spanish, French, and Dutch—there are a number of tongues spoken by non-European immigrants—Hindī, Urdū, and Chinese. Also, there are pidgin variants of the European languages known as creoles, which have become the common languages of many of the people. English and French creoles are the most widespread and are best developed in Jamaica and Haiti, respectively. Spanish creoles did not evolve in the major Spanish-language communities—Cuba, Puerto Rico, and the Dominican Republic. A variant called Papiamento, a Spanish-Dutch-Portuguese-English creole, is widely spoken in Aruba and the Netherlands Antilles. There is a marked correlation between whiteness and the use of standard language forms, though with a distinctive Caribbean accent, and blackness and creole usage: the association holds island by island and regionally.

Hindī, Urdū, and Chinese are languages of the home, and the younger generation are often no longer fluent in their use. In contrast, English creole has increased in significance in the Commonwealth Caribbean since decolonization; it is used extensively on radio broadcasts in Jamaica, and modern Jamaican novels, poems, and plays are often solely in English creole or move between it and standard English as the mood demands. A similar situation has existed for decades in Haiti, where the vast majority use French creole and neither read, write, nor understand standard French. The political incorporation of the French Antilles (Guadeloupe and Martinique) as overseas *départements* of France has resulted in the proliferation of standard French in those communities, while in Puerto Rico, Spanish is influenced by American English and by the so-called Spanglish (American English-Spanish) of returning migrants.

Religion.   Religious affiliation in the West Indies follows a pattern similar to that of language. Roman Catholicism is the predominant faith in the Spanish- and French-speaking islands, while Protestantism is the norm in the Commonwealth Caribbean and the Dutch territories. Among the masses, however, syncretic cults, a mixture of either Catholicism or Protestantism and African elements, prevail, notably in Haiti, Jamaica, and Trinidad and Tobago, though elements of the Afro-Christian tradition also occur in Cuba, Puerto Rico, and the Lesser Antilles.

In Trinidad and Tobago about three-fourths of the East Indian group, which accounts for some 40 percent of the population, has retained Hinduism and Islām, and, while the first half of the 20th century was characterized by Indian conversion to Christianity, the second half has witnessed strong revivals in Asian religions. In part this has been due to the political development of the Indian population; but it has also been the consequence of improved education and the emergence of sophisticated

young Hindus and Muslims who have responded to the more philosophical aspects of their religions, as distinct from the folk tenets of their forebears.

Hinduism and Islām apart, religion tends to coincide closely with colour and class. Upper-class whites and browns (mulattoes) in Jamaica tend to be Anglican, lower-class blacks largely followers of Protestant faiths such as the Church of God and the Baptist church. Similarly, voodoo (voudou, or *vodun*) in Haiti is a folk religion, although its practitioners frequent the Roman Catholic church for the major rites of passage associated with baptism, marriage, and death. In the Commonwealth Caribbean, obia (obeah), which is similar to black magic, is still used against enemies or to enhance the user's position; other sects, such as believers in myalism, are devoted to removing spirits and healing the sick.

Demographic trends. The West Indies have experienced a common demographic history: decimation of the Amerindian population by the Spanish in the Greater Antilles, and by the British and French in the Lesser Antilles, led to the introduction of African slaves to cultivate the sugar and coffee plantations of the European settlers during the 17th and 18th centuries. After the abolition of slavery in the British, French, and Dutch territories in the 19th century, Asiatic indentured labour was introduced for plantation work—notably from northern India. Since World War I, however, unemployment has been growing in most of the islands, exacerbated by a high rate of natural increase.

Recent demographic trends in the region have followed closely, if not led, changes occurring in developing countries elsewhere in the world. Improvements in health care and hygiene since 1920 have rapidly reduced the mortality rate, and the fertility rate, although in a downward trend, continues to be relatively high. Infant mortality has been reduced to less than 20 per 1,000 live births in Cuba, Puerto Rico, Jamaica, and Trinidad and Tobago, and most of the other territories—Haiti being a notable exception—have achieved a similar reduction. Birth rates remain high in most of the states. The rate of natural

Birth and death rates

increase, although still high, has shown a downward trend due in part to the availability of birth control—abortion (particularly in Cuba) and family planning. The total population growth, however, may be more seriously affected by opportunities for emigration. For example, between 20,000 and 25,000 Jamaicans a year have been settling in the United States and Canada since the 1970s. Much of this movement is legal and documented—educated West Indians have little difficulty in satisfying the skill criteria required by the U.S. and Canadian immigration authorities; and Puerto Ricans and French West Indians have virtually unrestricted access to the United States and France, respectively. In addition, there is a substantial undocumented migration, particularly from Haiti and the Dominican Republic, both within the West Indies and to external destinations, especially the United States.

The heavy emigration and high rates of natural increase notwithstanding, the dominance of large plantations and the limitation of small peasant plots, together with rural underemployment, have propelled West Indians into the towns, especially in the Greater Antilles and Trinidad, at a rapid rate. More than one-half of West Indians are now urban dwellers, but frequently under conditions of labour surplus and overcrowded housing that have led to the growth of shantytowns, an endemic condition throughout much of Latin America. Urbanization based on rapid natural increase and rural-to-urban migration has produced massive societally marginal populations, especially in the towns of Jamaica, the Dominican Republic, Haiti, and Puerto Rico.

THE ECONOMY

West Indian economies are largely underdeveloped and dependent upon foreign assistance, often from the former colonizing power. Although the sugar plantation remains dominant only in Cuba and Saint Kitts, its legacy is more widespread, as is reflected in the common heavy reliance on exports of primary agricultural and mined products of variable quality and in fluctuating quantities. The states are generally reliant upon sheltered markets in North

America and the European Economic Community to enhance their trade position, especially with regard to agricultural products. Economic diversification into industry, tourism, and mining, as a means of breaking from the single product economy, has produced only enclaves in most island nations, and modernization has been only partially achieved in most places and barely at all in others, such as Haiti. The reliance on one or a few products leaves most West Indian states highly vulnerable to fluctuations in market demand.

Government initiatives in some of the Greater Antilles and in such places as Trinidad and Tobago and Barbados have raised educational standards and improved health care services and communications, yet high unemployment and heavy reliance of urban labour on low-level jobs remain major economic problems. From time to time, governments have attempted to imitate Cuban socialism by nationalizing some sectors of the economy, as an alternative to U.S.-backed capitalism, operating in such places as Puerto Rico and the Dominican Republic. Despite such attempts, most West Indian states operate to one degree or another under a free enterprise system, although social programs are more heavily influenced by socialism. Cuba's centrally run economy is the main variant in the region.

National- ization

Resources.   While the West Indian islands were ideal for plantation agriculture during European colonial expansion in the 17th and 18th centuries, their subsequent development has been hampered by a lack of natural resources, especially the traditional mineral bases of heavy industry—coal and iron ore. During the 20th century, however, major petroleum, natural gas, and bauxite deposits have been identified and exploited. Petroleum and natural gas now provide the basis for Trinidad and Tobago's economy and are found in smaller but commercially viable quantities in Cuba and Barbados. Bauxite is mined by open-cast methods in Jamaica, Haiti, and the Dominican Republic;

Jamaica was once the world's largest exporter and is still a major producer of both bauxite and refined alumina.

Other mineral resources are rather sparse, although Cuba is one of the main producers of nickel, and some asphalt is taken from Trinidad's Pitch Lake. Hydroelectric potential is slight, and timber and fishing resources are inadequate for large-scale commercial development except in Cuba. The climate, however, is a powerful resource that is increasingly exploited in the interests of tourism.

Agriculture.   The process of modernization and industrialization has drawn West Indian populations away from agriculture, so that only in Haiti is most of the labour force devoted to farming. Nevertheless, agriculture remains dichotomized into peasant and plantation systems, located in the mountainous interior and on the fertile plains, respectively. Plantations are highly capitalized, employ labour, and are mechanized; many occupy land cultivated in sugarcane over the centuries, though now consolidated with central processing factories. Peasants, on the other hand, cultivate their own land, rely on hand labour, and make low capital investments. Often they possess no title to their land and engage in extended family ownership or sharecropping.

In the French- and English-speaking islands, where peasants are invariably black, they are the descendants of ex-slave ancestors who created the peasant farming system following emancipation in the first half of the 19th century. Throughout the West Indies, including Cuba, land distribution is still highly uneven. The majority of holdings are less than five acres (two hectares) and are too small and fragmented to be economically viable. A few large estates of more than 500 acres (about 200 hectares) monopolize the greater part of the cultivated area.

Uneven land distribution

Large estates are often monocultural enterprises producing such items as sugar, rum, and molasses, but many also raise cattle—notably in Cuba—and grow bananas, mangoes, and citrus fruits; indeed, some estates have abandoned sugar and switched to these other products. Peasant produce is usually consumed at home—especially such staples as yams, cassava, and sweet potatoes—as well as carried to the market or sent overseas. Since the 19th century, the peasantry has made a substantial contribution to the export economy: pimiento, ginger, cocoa, breadfruit, coffee, arrowroot, and nutmeg tend to be peasant crops; sugarcane and bananas are grown almost equally on small and large holdings. Livestock raising is not significant, although Cuba has relatively extensive grazing

land for cattle. The islands produce much of the meat that they consume.

Industry. Petroleum is the West Indies' major industrial resource and has given rise to an important refining industry in Trinidad and Tobago, based partly on imported crude oil. An oil boom between 1975 and 1982—stimulated by new petroleum finds and world price rises—enabled the Trinidad and Tobago government to invest in steel and petrochemical complexes, but they did not produce immediate profits. Several largely foreign-owned multinational companies have refining or storage facilities in the Antilles, but the oil refining on Aruba, based on Venezuelan exports, was shut down, and that on Curaçao survives only with Venezuelan support.

Since World War II Puerto Rico has attempted to diversify its economy by giving tax concessions to foreign investors to encourage them to set up factories that take advantage of a cheap labour supply; this policy of intentive industrialization has been copied—but with less success—in Jamaica, Trinidad and Tobago, Haiti, Barbados, and The Bahamas. Industries that have been attracted involve mostly light, capital-intensive operations producing plastic and metal products, garments, sportswear, and chemicals and pharmaceuticals, usually for the U.S. market. In Puerto Rico manufacturing is the largest contributor to the gross domestic product; elsewhere, that sector relies on the sugar industry. A major problem with assembly industries using imported components is that they create few jobs and are rarely linked to local agricultural resources. Similar criticism has been made of the free-port manufacturing zones in Jamaica and the Dominican Republic, set up to take advantage of U.S. concessions offered under the 1982 Caribbean Basin Initiative. These industrial developments, coupled to government commitments to raise standards of living, other than in Haiti, have strained energy resources, in terms of both installed energy capacity and the cost of oil imports.

Sun, sand, and sea are the major natural advantages of the West Indies' tourist industry, plus their location within easy flying and cruising time for the large pool of North American tourists. Since the 1950s the north coasts of Jamaica and Puerto Rico, the leeward coast of Barbados, and parts of Antigua have developed as major tourist resorts. Tourism is a major contribution to the economy of Jamaica and Puerto Rico and is dominant in Antigua, Barbados, and the Virgin Islands.

The Caribbean Basin Initiative

Trade. The West Indies remain trapped in a classic dependency position reflected by unfavourable terms of trade: exporting cheap primary products—agricultural crops and mineral ores and petroleum—and importing comparatively expensive manufactured goods, increasingly consumer durables (such as vehicles and appliances). Major markets are the European Economic Community—notably in the former colonial metropoles, the United Kingdom and France—and Canada and the United States. The latter is the West Indies' major trading partner, especially for imports, which include enormous quantities of food. Cuba, since 1959, has become as dependent on Soviet trade—and subsidies—as it previously was on the United States and that country's sugar quota.

Transportation. Highly dependent upon trade, the West Indies requires good seaport and airport facilities. St. John's in Antigua, Bridgetown in Barbados, and Montego Bay in Jamaica have developed deepwater landing facilities, while Kingston has become a container port (able to handle specially packed cargoes). Most of the islands have international airports that can handle jet passenger aircraft; elsewhere, the major tourist centres can accommodate the jumbo jets of the North American and European airlines.

Railways are important only in the larger islands, especially Cuba and Jamaica, where passenger services are maintained by systems that largely serve the sugar and bauxite industries, respectively. Major roads tend to follow the coast. Road networks are dense in Jamaica, Puerto Rico, and the Lesser Antilles but are difficult to maintain against the rainy season and hurricane damage. Only Cuba has a major highway serving the nation, in this case dating to the 1930s, but Trinidad and Tobago, Jamaica, and the French Antilles have some modern motorway sections.

History

Hispanic control of the West Indies began in 1492 with Christopher Columbus' first landing in the New World and was followed by the partitioning of the region by the Spanish, French, British, Dutch, and Danish during the 17th and 18th centuries. U.S. intervention in the Greater Antilles started in the early 19th century and culminated in the occupation of Cuba and annexation of Puerto Rico in 1898 and the purchase of the Danish Virgin Islands in 1917. Hence, each unit's connections—political, economic, and cultural—have been forged almost exclusively with the countries of western Europe or the United States. Soviet collaboration with Cuba since Fidel Castro's revolution in 1959 has perpetuated the history of great-power involvement in the West Indies. Before the colonization of the West Indies, however, pre-Columbian peoples there had evolved important and distinctive cultures.

THE PRE-COLUMBIAN PERIOD

Contemporary historians estimate that the Amerindian inhabitants of the West Indies numbered approximately six million in 1492—roughly one-fifth of the present-day total population. Three distinct Indian groups occupied the islands: the Ciboney, concentrated in the western parts of what are now Cuba and Haiti; the Arawak, located in the Greater Antilles and Trinidad; and the Carib, who lived mostly in northern Trinidad and the Lesser Antilles. Apart from a small reservation of Caribs in Dominica with some 500 members, mostly miscegenated with blacks, and a few scattered populations with Amerindian physical features in Cuba and Puerto Rico, the pre-Columbian population completely disappeared under the impact of culture shock, slavery, and diseases introduced by the Europeans.

Archaeologists divide the pre-Columbian populations of the West Indies into three chronological groups: the Paleo-Indians (5000–2000 BC), who were hunter-gatherers on the littorals of Cuba, Hispaniola, and Trinidad, and who probably originated in Central America; Meso-Indians (1000–500 BC), who were also hunter-gatherers but with a more sophisticated material culture—that of pottery, toolmaking, etc.—and who spread from South America to Trinidad and the Greater Antilles, where their remnants have been labeled Ciboney; and the Neo-Indians: first the Arawak, who entered Trinidad from South America about

Aboriginal Indian groups

300 BC and spread rapidly to the Lesser and Greater Antilles, only to be displaced from the Lesser Antilles after AD 1000 by aggressive Caribs, who migrated from Venezuela.

Arawak groups in the Greater Antilles shared a common life-style, language, and social organization. Their social structure was stratified and dominated by hereditary rulers called caciques, who may have had matrilineal lines of inheritance, and shamans controlled the Arawak's complex religious activity. The Arawak settled in villages that were established inland in forest clearings, and each village had its own chief, also called a cacique. Houses with circular ground plans, timber walls, and palm thatch roofs were arranged around a central open space. Villages were particularly plentiful in Hispaniola, usually with populations of between 1,000 and 2,000. Dancing and ball games were popular forms of recreation.

Arawak groups also exhibited throughout the Greater Antilles a uniform development in technology and techniques of subsistence. They fished, hunted, collected wild plants, cultivated kitchen gardens, and developed a system of shifting cultivation known as *conuco* for growing starch- and sugar-rich foods. The Spanish were impressed not only by their agricultural techniques but also by their use of fibres and their manufacture of canoes, gold ornaments, and pottery.

Carib villages in the Lesser Antilles, usually located on the windward coasts, were protected from surprise attack. Their social relationships were probably more flexible than those of the Arawak, and they had no hereditary caciques.

Carib culture

Many similarities, however, existed between Carib and Arawak material culture, especially with regard to *conuco* cultivation. While Carib pottery was inferior to that of the Arawak, their canoes and woven cloth were superior. Their houses, constructed of pole frames covered with palm thatch, were oval or rectangular.

EUROPEAN EXPLORATION AND COLONIALISM, 1492–1800

Discovery. With Columbus' voyage of discovery in 1492, the Caribbean Sea was transformed into a Spanish lake. Settlement by the Spanish concentrated on the Greater Antilles and above all on the densely populated island of Hispaniola (today divided into Haiti and the Dominican Republic), where the first permanent Spanish settlement in the Americas was established at Santo Domingo. Prospecting for precious metals led only to modest discoveries, but Santo Domingo rapidly became the "mother of settlement" in Latin America; the momentous expeditions to Mexico under Hernán Cortés and to Peru under Francisco Pizarro began from there. Their success diverted Spanish attention to the mainland in the 1520s, and Santo Domingo was soon superseded in commercial if not administrative significance by Havana (Cuba) and San Juan (Puerto Rico), which provided staging posts for the fleets of galleons transporting cargoes of bullion from the "Spanish Main" (the mainland bordering the Caribbean) to the Iberian Peninsula.

The Spanish missionary Bartolomé de Las Casas' intervention to prevent the genocide of the Indian population came too late to save the Arawak, although it did lead to the introduction of black slaves from Africa in the early 16th century, a solution to the Spaniards' labour problem that Las Casas had suggested. Small sugar industries were set up on a plantation basis in Cuba, Santo Domingo, and Puerto Rico, but they remained of minor significance and died out at the end of the 16th century. It was left to Sephardic Jews to introduce the sugar plantation to the British West Indies from northeastern Brazil in the 1640s, by which time the English and French had made colonial inroads into the Caribbean.

English conquests

Colonialism. England was by far the most successful of the northwestern European predators on the Spanish possessions. In 1623 the English occupied Saint Christopher (Saint Kitts) and in 1625 Barbados. By 1655, when Jamaica was captured from a small Spanish garrison, English colonies had been established in Nevis, Antigua, and Montserrat. France took control of Guadeloupe and Martinique in 1635 and in 1697 formally annexed Saint-Domingue (Haiti), the western third of Hispaniola, which for about half a century had been occupied by buccaneers

and French settlers. Curaçao, Aruba, and Bonaire, off the coast of present-day Venezuela, and Sint Eustatius, Saba, and half of Saint Martin (Sint Maarten), in the northern group of the Lesser Antilles, became Dutch possessions in the 1630s, but more as part of the military strategy of the Dutch war of independence against Spain than in expectation of agricultural riches.

These major gains against the Spanish were concentrated in the Lesser Antilles, which were poorly defended and essentially under Carib control. Only Jamaica and part of Hispaniola were wrested from the Spanish empire in the Greater Antilles, and Havana and San Juan continued to play a crucial part in Latin-American–Iberian trade until Spain lost its mainland empire through independence in the 1820s. The French and British continued to dispute the Lesser Antilles throughout the 18th century, and by the early 19th century Dominica, Saint Lucia, Saint Vincent, Tobago, and Grenada were in British hands, while Trinidad was formally ceded to Britain by Spain in 1802.

Plantation slavery. During the second half of the 17th century colonialism was linked to mercantilism (based on establishing gold and silver reserves and a favourable trade balance) and, in the British and French possessions in particular, to sugar plantations using slave labour imported from West Africa. The object of each of these imperial systems was to extract profits from the systems of trade in sugar, slaves, and manufactured goods. Mercantilism was most fully expressed in what is referred to as the triangular and quadrilateral trades; in their most complicated form these linked Europe, West Africa, the West Indies, and the eastern seaboard of what is now the United States in reciprocal commerce largely for the benefit of the British, French, and Dutch. Mercantilism peaked in the 18th century, before being replaced by the industrial capitalism that it had nurtured.

A major feature of white settlement in the West Indies was its transitory nature. The object of white adventurers, especially the British, was not to stay permanently in the West Indian colonies but to return to Europe with their fortunes made. Absenteeism became well established during the early 18th century, when many successful planters retired to Britain leaving representatives in charge of their estates. These absentees were a crucial element in the West India Interest, a powerful lobby that brought together merchants from the major ports, planters, and parliamentarians. It was the West India Interest that engineered the Molasses and Sugar acts in the first half of the 18th century. These acts protected British West Indian sugar in the British market and increased the prosperity of the planters.

The absentee planter

The power of the plantation was not confined to the economic sphere. It created an inegalitarian social hierarchy based upon racial distinctions and law. During the 17th century the major strata of West Indian society were free whites and black slaves, and, when by the mid-18th century miscegenation had become more prevalent, an intermediate mulatto stratum was formed through the manumission of the illegitimate offspring of the white elite. By law, however, whites alone were full citizens; the emancipated mulatto population exercised only limited civil rights, as did the increasing body of free blacks. Slaves, whether black or the illegitimate mulatto offspring of poor whites, were nonpersons, chattels to be bought and sold. Status and power were inversely related to group size; in Jamaica in the early 19th century, 25,000 whites dominated a colony with 40,000 mulattoes and 340,000 blacks.

THE WEST INDIES SINCE THE 19TH CENTURY

Emancipation. West Indian Creole societies were shaken by the successful slave rebellion in Saint-Domingue in the 1790s that resulted in Haiti's independence in 1804, thus creating the first black republic in the Americas. In 1807 Britain abolished the slave trade, and in 1833 slavery itself was abolished in the British West Indies. The French enacted emancipation in 1848 and the Dutch in 1863. But while these changes were taking place in the British, French, and Dutch West Indies, Spanish Cuba was developing as a slave-plantation producer of sugar. Slave imports into Cuba, despite a British naval blockade,

turned the island into a predominantly black and mulatto society by the second half of the 19th century. Full emancipation was not enacted in Cuba until 1886, 13 years after it was accomplished in Puerto Rico, where tobacco was more important than sugar and where slaves made up less than 5 percent of the population. Subsequent free white immigration, especially for plantation work in the early 20th century, once again transformed Cuba into a white society with a Hispanic culture.

Nineteenth-century emancipation created fewer changes than the slave owners feared, largely because most of the best land was in plantations and because property-restricted franchises—especially in the British West Indies—favoured the established order. Nonetheless, emancipated slaves were free to sell their labour, migrate, squat, or purchase land. A "reconstituted" peasantry emerged in Haiti, Jamaica, and the Windward Islands. In the larger Leewards and Barbados the ex-slaves were unable to acquire land because of the lack of a mountainous interior, and the mountainous land on other islands was all that was available to the former slaves; thus they remained as plantation workers or emigrated to Central America or the United States. Cuba's emancipated blacks were soon caught up in the war of independence with Spain; their descendants were later drawn into the burgeoning sugar industry developed by U.S. capital, much as mulattoes had been in the Dominican Republic and as whites would be in Puerto Rico.

The persistence of the plantation system and of white elitism, bolstered by colonialism, shored up the structure of the grossly inegalitarian societies of the West Indies after emancipation. Colour-class and culture-class correlations persisted in a situation where—excepting the French West Indies from the late 19th century—democracy was systematically denied. The complexity of the white-brown-black social hierarchy was compounded in some islands by the arrival of other ethnic groups. Chinese indentured immigration to Cuba; East Indian indentured immigration to Trinidad and to a lesser extent to Jamaica, Martinique, and Guadeloupe; and free movement of Chinese, Portuguese, Syrians, and Lebanese to Trinidad and the Greater Antilles (mainly in the 20th century) produced minorities with the potential for social mobility. But, whereas the Portuguese, Syrians, and Lebanese (like the Jews before them) used trade to achieve mobility, the East Indians remained largely tied to rural enclaves, even in Trinidad, where they have come to account for more than 40 percent of the population.

Decolonization. Radical changes in the social position of nonwhites has depended less upon emancipation than on decolonization. Having liberated themselves in 1804, the Haitians in the early 1820s invaded Santo Domingo and incorporated the former, almost forgotten Spanish colony into a Hispaniola-wide Haiti. In 1844, Dominicans rejected Haitian hegemony and declared their sovereignty. Later they reverted briefly to the Spanish crown and achieved their final independence in 1865. The third independence from a European power in the West Indies was Cuba's, in 1898, and it involved not only two wars of independence with Spain but also U.S. intervention. Cuba achieved formal independence from the United States in 1902 but remained a fief of its northern neighbour until the Platt Amendment was abrogated in 1934. By this time labour disturbances were about to break out throughout the region, generated by an international economic depression and the lack of means for democratic dissent; popular demands for development and decolonialization were spreading from Jamaica to Trinidad.

Most of the West Indian societies were decolonized with imperial consent after World War II, either by a grant of full independence, as in the case of most of the British territories; by incorporation into the mother country, as in the French Antilles; or through their association with the mother country, as in the Netherlands Antilles and some of the British territories. All these methods of decolonization have been endorsed by the United Nations. Nevertheless, Britain still retains several small West Indian dependencies, most of which have shown little interest in independence: Montserrat, Anguilla, the British Virgin

Islands, the Cayman Islands, and the Turks and Caicos Islands.

When World War II ended in 1945, only three West Indian states were independent—Haiti, the Dominican Republic, and Cuba—and all either were or were about to become dictatorships. When the British, French, and Dutch began to decolonize, either by liberating or incorporating their territories, a major preoccupation was the establishment of democracy. In pursuit of this objective the British tried to create an interisland federation that would incorporate more checks and balances than was feasible in a unitary state, as well as provide a vehicle for small-island decolonization. It was the failure of this policy with the breakup of the West Indies Federation (1958–62) that led to the first phase of independence (1962–66), the second stage of independence involving the Bahamas and the British associated states (1973–83), and the ultimate recognition by Britain of a residual and continuing category of dependencies.

Dependency. If most West Indian political units are no longer colonial, dependence remains the hallmark of Caribbean economies. For decades the terms of trade, for example, have operated against West Indian primary producers; except for oil-rich Trinidad, none of the West Indian islands produces enough of any one major commodity to have a decisive role in fixing prices. More damaging in many cases than the terms of trade has been the penetration of each island economy by foreign enterprise. Neocolonialism prevails in most islands, and West Indians are acutely aware of their dependence on overseas capital, decision makers, and technologies, particularly in the French Antilles.

The importance of multinational corporations in West Indian economies is reflected in the preeminent position of North American companies in the Jamaican, Haitian, and Dominican Republican bauxite industries and in Trinidad's petroleum economy; the role of the British-based company Tate and Lyle in West Indian sugar production and refining; and the monopolistic position of both British and North American companies in the marketing of bananas from Jamaica and the Windward Islands.

Notwithstanding these constraints on sovereignty, the 1970s and '80s witnessed substantial nationalization of foreign-owned enterprise in the West Indies because of pressure from governments and, in the Commonwealth Caribbean, as a result of the willingness of companies to surrender their least viable operations and to use the compensation to open up activities elsewhere. The West Indies Sugar Company, a subsidiary of Tate and Lyle, divested itself first of sugarcane land, then of factories in Jamaica and Trinidad, and Jamaicans and Trinidadians now hold an interest in foreign banks. Trinidad and Tobago has purchased significant North American petroleum assets, and Jamaica in the 1970s concluded participation agreements with several North American aluminum companies. Almost half of the hotel industry in Jamaica fell by default into government hands as a result of the catastrophic reduction in visitors from North America after 1976, following the negative reports about Prime Minister Michael Manley's socialist policies in the U.S. press. None of the other Greater Antilles has approached Cuba's post-1959 policy of wholesale nationalization within an ideological framework of Marxism; but, at the other extreme, the nations of the Lesser Antilles—except for Grenada during the People's Revolutionary Government (1979–83)—have not made any concessions to national involvement in, or ownership of, the leading economic sectors. In the 1950s it was expected that decolonization would deliver more than halting development of dependent economies under generally conservative elites. When compared to the example of oppression and impoverishment in Haiti after 30 years of Duvalierist and post-Duvalierist rule, however, the British, French, and Dutch former colonies can be said to have made considerable social and economic progress under generally democratic governments. Indeed, the process of democratization—one of the major goals of decolonization—is largely regarded to have moved successfully. However, governments remain unclear on how the benefits of self-determination can be extended into

Plight of the ex-slaves

Types of independence

Democratization

grass-roots economic development and social change, although some countries, Jamaica in particular, have made considerable progress in breaking the real and psychological ties of dependency.

THE GREATER ANTILLES

Cuba

Cuban archipelago

The Republic of Cuba comprises the Cuban archipelago, a formation of about 1,600 islands, islets, and cays with a combined area of 42,804 square miles (110,861 square kilometres). This archipelago is situated just south of the tropic of Cancer at the entrance to the Gulf of Mexico and forms an important segment of the Antilles island chain, which continues east and then south in a great arc enclosing the Caribbean Sea. The island of Cuba itself—the "Pearl of the Antilles"—is by far the largest island in the chain, covering 40,519 square miles (104,945 square kilometres). In general the island runs from northwest to southeast and is long and narrow—777 miles (1,250 kilometres) long but only 119 miles (191 kilometres) across at its widest and 19 miles (31 kilometres) at its narrowest point. The capital is Havana, on the northwestern coast. Haiti, the nearest neighbouring country, is 48 miles away across the Windward Passage; Jamaica is 87 miles to the south; and the United States is about 90 miles to the north across the Straits of Florida.

The Isle of Juventud (Isle of Youth; formerly called Isla de Pinos [Isle of Pines]), is the second largest in the archipelago (849 square miles); it rises to the southwest of Cuba itself. Other archipelagoes are the Los Colorados, to the northwest; Sabana-Camagüey, off the north central

coast; the Jardines de la Reina (Queen's Gardens), near the south central coast; and the Canarreos Archipelago (technically including the Isle of Juventud), along the southwest coast.

Because of its location and natural resources, Cuba was coveted by more than one foreign power over the centuries. A colony of Spain after its discovery by Columbus in 1492, it formally became a republic at the beginning of the 20th century, although with a high degree of political and economic dependence on the United States. On New Year's Day, 1959, revolutionary forces led by Fidel Castro won a civil war and took power. In 1961 the Marxist-Leninist nature of the revolution was proclaimed. Revolutionary Cuba developed close links with the Soviet Union; the dissolution of the latter in 1991 brought economic strain and uncertainty to Cuba.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* Mountains cover about a quarter of the total area of the island of Cuba. They are often interrupted by the plains that cover some two-thirds of the surface. The coastal basins of Santiago de Cuba and Guantánamo lie in the extreme east; a great central valley also begins in the east and then combines with a peneplain that continues westward across the island. These plains have been hospitable to sugarcane and livestock raising.

The *alturas*—regions of moderate elevation—are in some cases residues of formerly higher surfaces. More rugged relief includes the Guaniguanico range in the west, comprising the Sierra de los Órganos and the Sierra del Rosario, which attains 2,270 feet (692 metres) at El Pan de Guajaibón; the Sierra de Trinidad in the central region, with the 3,793-foot (1,156-metre) San Juan Peak; and the Sierra Maestra, on the southeast coast, approximately 150 miles long and containing the island's highest peaks, with Real del Turquino Peak at 6,476 feet (1,974 metres) preeminent.

Cuba possesses an irregular 3,570-mile coastline, made picturesque by many bays, sandy beaches, mangrove plantations, swamps, coral reefs, and rugged cliffs. There are also some spectacular caverns in the interior, notably the Cave of Santo Tomás of the Quemado ridge region, which has a linear extension of 16 miles. The island of Cuba is surrounded by a submerged platform that is an additional 30,000 square miles (75,000 square kilometres) in area.

Drainage and soils. Cuba's supply of groundwater is utilized throughout the island but especially in La Habana province. The rivers are generally short, with very meagre flow; of the nearly 600 watercourses classified as rivers, two-fifths discharge to the north, the remainder to the south.

The island's heaviest rainfall and therefore its largest rivers are in the southeast, where the Cauto (at 230 miles the country's longest) and its tributaries, notably the Salado, drain the Sierra Maestra and the uplands to the north. Other major rivers in this region include the Guantánamo, Sagua de Tánamo, Toa, and Mayarí. To the west the most important southward-flowing rivers are the Sevilla, Najasa, San Pedro, Jatibonico del Sur, Zaza, Agabama, Arimao, Hondo, and Cuyaguateje; northward-flowing rivers include the Saramaguacán, Caonao, Sagua la Grande, and La Palma.

Cuban lakes are small and more properly classified as freshwater or saltwater lagoons. The latter include the 26-square-mile Leche Lagoon (Milky Lagoon), which is technically a sound, being connected to the sea by several natural channels. Sea movements generate disturbances in the calcium carbonate bottom deposits to produce the milky appearance.

The complicated Cuban topography and geology have produced soils of no fewer than 13 different major groups, the majority of which are fertile and amenable to year-round cultivation. Highly fertile red limestone soil extends

The Sierra Maestra mountains overlooking the port of Santiago de Cuba along the country's southeastern coast.

from west of Havana to near Cienfuegos on the southern coast and lies in extensive patches in western Camagüey province, providing the basis for Cuba's main agricultural output. Another area of fertile soil is north of Cienfuegos between Sierra de Sancti Spíritus and the Caribbean coast. Camagüey province and the Guantánamo basin have some arable land, although of lower fertility. Areas of sandy soil in Pinar del Río, Villa Clara, and portions of Ciego de Ávila and Camagüey cannot hold moisture and are of low fertility, as are the soils of the mangrove-dotted coastal swamps and cays.

Climate. Cuba lies in the tropical zone, located on the southwestern periphery of the North Atlantic high atmospheric pressure zone and hence influenced by the northeast trade winds in winter and east–northeast winds in summer. The warm currents that form the Gulf Stream have a moderating influence along the coasts.

Annual mean temperature is 79° F (26° C), with little variation between January (at 73° F [23° C] the coolest month) and August (the warmest month, at 82° F [28° C]). The November–April dry season abruptly changes to the rainy May–October season. Annual rainfall averages 54 inches (1,380 millimetres). Between June and November, the country often is exposed to hurricanes, whose strong winds and heavy rains have occasioned great economic damage and human suffering.

Plant and animal life. Cuba's tropical plant life is very rich, with some 8,000 species represented, 7,000 of them flowering plants; half of these are endemic. Much of the original vegetation has been replaced by sugarcane, coffee, and rice plantations, made possible by enormous and indiscriminate destruction of forests. The revolutionary government introduced extensive reforestation for both economic and conservation reasons.

Cuban timber is of excellent quality, although the supply is limited. Pine is found in abundance, and the durable mahogany is of potential economic importance, while ebony (*Diospyros*) and granadilla (cocus, or West Indian ebony; *Brya ebenus*) are both beautiful and valuable. The abundant royal palm, reaching heights of 50 to 75 feet, is the national tree and a characteristic element of the rural landscape. The ceiba (kapok) tree plays a role in many legends, while the extremely rare cork palm (*Microcycas calocoma*) of the western regions is a "living fossil," thought to have survived for more than 100 million years.

Fruit trees include such citrus varieties as lemon, orange, and grapefruit; some species of the genus *Annona*, including the *guanábana* (soursop) and *anón* (sweetsop); and avocado and papaya. Banana plants are also common. The lower Cuban coasts and the shoals of the archipelago are given marked character by the mangrove, and the tobacco plant is commercially prized.

Cuban animal life is extraordinary in its abundance and variety, particularly the invertebrate species. The archipelago is the home of more than 7,000 insect species and 4,000 species of land, river, and sea mollusks. Commercially valuable sponges are found off the southwestern coast, and edible crustaceans abound. Similarly profuse, arachnids include the tarantula and scorpion. Fish, with more than 500 species (many edible), are economically the most important vertebrate group; there are about 35 species of shark. Freshwater fishes are considerably less abundant. Cuba is visited by many migratory birds. Only about a third of the 300 or so species found on the island are indigenous; these include the flamingo, royal thrush, and nightingale.

Reptiles are distributed equally among sea, river, and dryland species. Marine species include the tortoise and hawkbill turtle; mud turtles inhabit the rivers; and the marshes contain two species of crocodile, once almost extinct but preserved through a repopulation program. Land reptiles include the iguana and the nonpoisonous *majá de Santa María* (*Epicrates angulifer*), Cuba's largest snake; none of the snake species are venomous. Amphibians are similarly varied, with 60 frog and toad species, the former including the plantain frog (*Hyla septentrionalis*) and bullfrog. The solenodon (*Atopogale cubana*), an almost extinct, ratlike insectivore, is found only in the remotest eastern regions. Other mammals include the hutia (an edible rodent) and

the manatee, or sea cow, which inhabits river mouths. A variety of bat species destroy mosquitoes as well as insects harmful to agriculture and in their roosting caves produce accumulations of guano that is valuable as fertilizer.

Settlement patterns. The various areas of Cuba do not differ greatly in customs and traditions, making a clear regional division on this basis difficult. Given this qualification, a division of Cuba into five geographic regions—Occidental (Western), Central, Camagüey-Maniabón, Oriental (Eastern), and the Isle of Juventud—is still possible on the basis of natural endowment and human exploitation.

The largest of Cuban regions, the Occidental region is 332 miles long and includes the provinces of Pinar del Río, La Habana, Ciudad de la Habana, Matanzas, and parts of Villa Clara and Cienfuegos. Its topography is notable for the *mogotes,* unusually shaped elevated hummocks, although it is primarily composed of an enormous plain that occupies its entire southern section. The 110-mile-long Cordillera de Guaniguanioo and the serpentine highlands of northern and central La Habana and Matanzas provinces further characterize the region. The Occidental region contains about 40 percent of the country's population and includes Havana, the largest city and the major Cuban economic, cultural, and administrative centre. The regional economy is based on agriculture (some of the best tobacco in the world, citrus fruits, sugarcane, cattle, rice, and coffee), manufacturing, copper and iron mining, tourism, and fishing.

The Central region extends from the Manacas plain (west of the city of Santa Clara) to La Trocha plain in Ciego de Ávila province and includes the Trinidad and Sancti Spíritus highlands and lesser uplands, interspersed with plains and boggy regions in the province of Sancti Spíritus. It also includes the archipelago of Sabana–Camagüey. The major Cuban tobacco-growing area, the Central region also produces sugarcane, cattle, citrus fruits, and coffee as well as marble, copper, iron, and limestone. Industrial activity in the region is varied. Santa Clara is the region's main centre of population.

The Camagüey–Maniabón region, Cuba's main stock-raising area, centres on an ancient peneplain that extends over central Camagüey province and northwestern Las Tunas province between La Trocha plain and the Maniabón highlands. Other prominent economic activities include the cultivation of sugarcane, rice, and grains, mining of chromium, and processing of cement, fertilizer, and gypsum. Camagüey is Cuba's third largest city and the region's main population centre.

At the eastern tip of the main island is the Oriental region, including the province of Granma and parts of Holguín, Santiago de Cuba, and Guantánamo. There are the nation's highest mountains, fastest streams, richest mines, and most spectacular bays. The Sierra Maestra rises along the southern coastline, the Sierra del Cristal and other ranges on the northern, and between them lies the economically important central valley, the easternmost portion of which rises to the Sagua–Baracoa highlands, which are covered by the most extensive forests in Cuba. The region contains nickel reserves and produces chromium, iron, copper, and manganese as well as sugarcane, coffee, and other agricultural items; its industrial centres process minerals and food and generate electric power. It includes Cuba's second largest city, Santiago de Cuba.

The Isle of Juventud, dotted with groves of pine and palm, has sand and clay plains in the north and hills in both the northwest and southeast; much of the island, however, is taken up by the gravel bed in the south and by the bogs of the coasts and uninhabited interior. At one time sparsely populated, it became the object of government resettlement projects in the mid-1970s. The cultivation of citrus fruits was established as the basis for the island's economy. Nueva Gerona is the island's capital.

The people. *Ethnic distribution.* For more than four centuries, diverse ethnic groups have been settling in Cuba. Not only Spaniards and Africans (the predominant elements) but also Chinese, Jews, and Yucatecans (from the Yucatán in Mexico) have all superimposed their cultural and social characteristics on those of the earliest settlers.

Contemporary Cuban society exhibits a remarkable diversity as a result.

Cuba's original inhabitants probably came to the island from South America. They were the Guanahatabey and the Ciboney, the former living in the extreme west of the island, the latter in various places in the island and particularly on the cays to the south. Both were hunter-gatherers. The Taino (Arawakan Indians), who arrived later and who spread over not only Cuba but also the rest of the Greater Antilles and the Bahamas, lived in villages and had rudimentary agriculture; they also made simple pottery. The Taino constituted 90 percent of the island's population at the time of the Spanish conquest.

At the beginning of the 16th century the total indigenous population was estimated at about 112,000, very unequally distributed, with density decreasing westward. Half a century after the Spanish invasion, however, only about 3,000 scattered individuals remained. Harsh treatment by the invaders, hard labour in the gold mines, hunger resulting from low agricultural productivity, suicides, and contagious diseases introduced by Europeans had all taken their toll. A few families with Taino physical characteristics living in the Sierra del Purial of easternmost Cuba are perhaps the only surviving descendants.

White Cubans, who constitute about two-thirds of the total population, are almost entirely of Spanish origin. Throughout Cuban history the dominant classes were primarily the Europeans and their descendants, white and mestizo (the latter being of particular importance in the 20th century), who monopolized not only the direction of the economy but also access to education and culture.

The Spaniards soon imported African slaves (approximately 760,000 in all, most of them for work on the sugar plantations) as a substitute for the rapidly disappearing Indians. The Africans came mainly from Senegal and the Guinea Coast, with diverse origins that included Yoruba and Bantu tribal backgrounds. Between 1919 and 1926 some 250,000 black Antillean labourers, 90 percent from Haiti and Jamaica, arrived under labour contract; nearly all remained. By the 1980s blacks and mulattoes made up one-third of the population. Their cultural influence has been considerable, especially in music and dance.

In order to supplement the interrupted slave trade, the Hispano-Cuban landholders imported 125,000 indentured Chinese labourers, nearly all of them Cantonese, between 1853 and 1874 to work under contract for eight years. Bad living conditions reduced their numbers to 14,000 by the census of 1899. In the 1920s an additional 30,000 Cantonese and small groups of Japanese also arrived; both immigrations were exclusively male, and there was rapid intermarriage with white, black, mulatto, and mestizo populations. In contemporary Cuba the Asian element makes up less than 1 percent of the total population.

Linguistic composition. Spanish is the Cuban national language; there are no local dialects, although the diversity of ethnic origins has influenced speech patterns. Some words are of native Indian origin, and a few (such as *hamaca* ["hammock"]) have passed into other languages. Africans have also enriched the vocabulary and contributed the soft, somewhat nasal accent and the rhythmic intonation that distinguish contemporary Cuban speech.

Religions. Among the religions in Cuba are Roman Catholicism, Santería (a cult devoted to certain African divinities formally identified with Catholic saints), and a number of Protestant, Jewish, and other groups. Prior to the revolution Roman Catholicism was predominant, although permeated by Santería and rather weak in rural areas. In the early 1960s church and state confronted one another with open hostility, the church seeing the revolutionary government as antireligious (one aspect of this being the nationalization of all schools) and the government seeing the church (the largest mass organization in the country) as a repository of counterrevolution. In the first half of the 1960s about 70 percent of all Roman Catholic priests, 90 percent of the nuns, some Protestant clergy, and all rabbis left the country either voluntarily, under social pressure, or through deportation. By the late 1960s relations between Roman Catholic and Protestant churches and the state had begun to improve; the 1976

Marginal notes:

Aboriginal peoples

Indentured Chinese

constitution proclaimed scientific materialism as the base of the state and education but recognized and guaranteed religious freedom, although with restrictions. By the 1980s both the church and the government had made some concessions and had entered a period of rapprochement.

Demographic trends. Prior to 1960 immigration was a contributing factor in the total population growth of Cuba, but since that year the number of persons leaving the country has outnumbered new arrivals, and the growth of the population has been mostly a consequence of changing birth and death rates. The birth rate rose steadily from 1958 to 1963, owing to the increased standards of living and expectations among low-income groups, increased sexual freedom among females, and larger numbers of women marrying at a younger age. On the other hand, there were increasing rates of death and infant mortality, caused by a mass exodus of physicians, a scarcity of medicines, and a rise in contagious diseases.

Trend
of vital
statistics

In the mid-1960s the high birth rate stabilized and began to decline as increasing numbers of females entered the labour force, sex education improved, strict limitations on consumption were instituted, housing became scarce, and compulsory military service at age 16 was initiated. By 1978 the birth rate had declined by more than one-half of its 1960s peak of 35 births per thousand persons. In the early 1970s the mortality rate also dropped as more physicians were trained and became available, the supply of medicines increased, and contagious diseases were controlled through vaccinations. In succeeding years, however, a slightly increasing trend in the mortality rate developed because of population aging. The combined effect of the declining birth rate and heavy emigration has resulted in a rather dramatic decrease in the overall rate of population growth.

The economy. By the end of the 1950s Cuba had developed one of the leading economies among Latin-American nations. Nevertheless, the country was confronted by a number of major problems: a sugar monoculture (sugar accounted for four-fifths of total exports), a low rate of economic growth, a heavy dependence upon the United States for investment and trade, high rates of unemployment and underemployment, and significant inequalities between urban and rural areas and among the various ethnic divisions.

When the revolutionary government took over in 1959, it set out to correct these problems through various means, the most significant being collectivization of all means of production (except for 9 percent of agricultural land); establishment of a centrally planned economy; emphasis on industrialization and deemphasis of sugar production (both later reversed); formation of close economic ties with the Soviet Union; and strong development of social services, particularly in rural areas.

The measures taken achieved mixed results. The attempt to introduce central planning (following the Soviet model of the 1950s) in 1961–63 failed because of the lack of infrastructure and qualified personnel and because of overly ambitious goals. After a period of intense debate (1964–66), the role of the central plan was reduced and emphasis placed on moral incentives (nonmonetary awards such as medals and titles, labour mobilization, and the development of the "new man" [1966–70]). When this approach also failed to bring about the desired results, there was a return to Soviet-type central planning and the orthodox system of socialist incentives. Even as the Soviet Union began experimenting with market mechanisms in the mid-1980s, Cuban leaders rejected the possibility of altering the economy. The fall of communist governments throughout Europe and the breakup of the Soviet Union in 1991 had deleterious effects on Cuba, which had received substantial economic aid from the Soviet Union. The policies of the government were more successful in reducing unemployment (to about 3 percent of the labour force), although at the cost of overstaffing state enterprises and lowering labour productivity, and sharply reducing income and urban-rural inequities. Economic growth rates have been erratic and relatively low; periodic experiments with moral incentives have provoked economic slowdowns and negative growth rates. Sugar continues to account for about three-fourths of exports, but there has been significant development of domestic industry.

The directorate of the Communist Party of Cuba is the planning agent for all phases of the Cuban economy. The institutional economic structure consists of the Central Planning Board, headed by the economics minister; the ministries and national organizations that control the economic sectors and basic activities; the various state enterprises (*empresas*); and the provincial delegations that direct the work of the factories and related services. Wages and prices are rigidly controlled, and quota systems strictly enforced.

The
national
planning
mechanism

Resources. Cuban soil is fertile, allowing for up to two crops a year, but agriculture has been traditionally plagued by the unreliability of the annual rainfall. Subterranean waters are an important additional resource for the country.

Petroleum deposits supply only a small percentage of the nation's needs, and the rest is met by imports. Peat, concentrated in the Zapata Peninsula, is still the most extensive fuel reserve. Nickel, chromite, and copper are the most important minerals mined, and the laterite (iron ore) beds in Holguín province have considerable potential. Nickel ore, which also yields cobalt, is processed in several large plants, and Cuba is a world leader in nickel production. There are also major magnetite and manganese reserves and lesser amounts of lead, zinc, gold, silver, and tungsten. Abundant limestone, rock salt, gypsum, and dolomite reserves and large kaolin and marble beds are also found on the Isle of Juventud.

Agriculture and fisheries. The Cuban economy remains heavily dependent upon the sugarcane crop, as it has since the end of the 18th century. Vast areas have been leveled and brought under irrigation, thus greatly expanding the acreage in sugarcane and yields per acre have been increased with the application of fertilizers. Sugar output, except in years of drought or sugarcane blight, increased after the introduction of mechanized harvesters in the early 1970s.

The number of cattle was increased in the 1960s by cessation of slaughter of reproducing cows, by irrigation projects that added to available pasture, by artificial insemination, and by expanded veterinary services. Brahman (or Zebu) cattle, the dominant breed (resistant to tropical climate but low in milk yield), were crossed with Holsteins (productive but prone to illness in the Cuban environment) and also with Brown Swiss in an unsuccessful attempt to produce acclimatized meat and milk producers. The number of cattle decreased sharply during the period 1967–86.

Improvements
in stock
breeding

Apart from sugarcane, the chief agricultural products are rice (the main source of calories in the traditional diet) and citrus fruits, the latter an important export crop. Tobacco, traditionally the country's second crop, is grown mainly in the Pinar del Río area in the west and also in the centre of the island; production has slowed, however. Other products include bananas, coffee, cocoa, pineapples, sweet potatoes, potatoes, corn (maize), cassava, and beans. Cuba has found it necessary to import large amounts of food (particularly rice), oilseeds, and cotton.

Fishing resources are significant. Fish and other seafood production increased overall sevenfold during the period 1959–79, although fluctuations were common. The increase occurred largely because of government investment in fishing vessels and processing plants; however, the institution of fishing zones by neighbouring countries since the 1980s adversely affected the industry.

Industry. Official sources are not clear on the relative value of industry in the Cuban economy since the Castro revolution, some showing a slight decline, others indicating an increase. The output of nickel, Cuba's most important metal, declined in the early 1960s, recuperated in the 1970s, and stagnated in the 1980s; construction of new nickel complexes began in the 1970s, but completion was delayed through the 1980s. Petroleum output has expanded dramatically but by the end of the 1980s met less than 10 percent of domestic needs. Nevertheless it is the main source of power. Production of hydroelectric energy is minimal, but completion of a nuclear power

plant was projected to bring Cuba its first nuclear power. Food processing (including sugar), beverages, and tobacco combined account for approximately one-half of the value of total industrial output; construction materials, chemicals, electricity, and fuels for one-fourth; and such items as textiles, clothing, and steel the remainder. In the late 1950s close to 300,000 tourists, mostly from the United States, visited Cuba each year. By the early 1970s tourism dropped drastically, but it made a comeback in the 1980s.

Finance. The banking system has been operated by the state through the National Bank of Cuba since 1966. There are no stock exchanges. Prices are centrally fixed, and investment is allocated by the national economic plans. With its controlled economy, inflation has been negligible, although there was a 12-percent increase in the early 1980s. Under the guidelines of the revolution, foreign investment was prohibited until 1982, when a joint-venture law was enacted; this, however, has failed to attract substantial investment.

Trade. In the 1950s more than two-thirds of Cuban foreign trade was with the United States. By 1961 this was down to 4 percent, and it soon dropped to zero under U.S. government embargo policies. Trade shifted to the Soviet Union and other socialist countries, and in 1972 Cuba became a full member of the Eastern-bloc Council for Mutual Economic Assistance (Comecon, disbanded in 1991). By the end of the 1980s almost three-quarters of Cuban trade was with the Soviet Union. Cuban trade suffered large setbacks with the dissolution of the Soviet Union. Trade with the latter had been on extremely beneficial terms that the noncommunist successor nations were unlikely to continue. The composition of exports has changed little: sugar continues to dominate, amounting to some three-fourths of the total, followed by nickel, fish products, citrus fruits, and tobacco. Import composition has changed dramatically in some areas: the share of machinery and transportation equipment has remained about the same (one-third), but the share of fuels and minerals has tripled (to one-third), while that of manufactured goods and food products have been cut in half.

Transportation. Cuba's merchant fleet has grown to keep pace with the increase in foreign commerce, but it nevertheless can handle only a small percentage of the country's shipping and must rely on foreign fleets for the bulk of the trade. The major ports are Havana (fuels, grains, and other commodities), Cienfuegos (sugar exports), Santiago de Cuba, Guayabal, Matanzas, Antilla, Nuevitas, Mariel, and the U.S. naval base at Guantánamo.

The railway constructed between Havana and Bejucal in 1837 was the first in the Americas after those of the United States. The railway system deteriorated in the first years after the revolution of 1959, but much of it has been restored and most of the system continues to serve the sugar industry.

The most important highway is the Central Highway, built in the 1920s; it runs along almost the entire length of the island. Other major routes are the Vía Blanca (linking Havana with the Playa Varadero) and the Vía Mulata (connecting Baracoa, at the east end of the island, with the rest of the country). There are state transport enterprises (mostly for passenger traffic), one of which is national, the rest being provincial in scope. Automobile transport has been substantially downgraded because of the sharp curtailment of auto imports since the 1960s.

The Cuban Aviation Enterprise (Empresa Cubana de Aviación), or Cubana, operates the former four private airlines. International airports operate at Havana, Santiago de Cuba, Camagüey, and Varadero.

Administration and social conditions. *Government.* Until the adoption of the constitution of Feb. 24, 1976, Cuba had for some 36 years been governed either by the constitution of 1940 or by the postrevolutionary Fundamental Law of Feb. 7, 1959, modeled upon the constitution but centralizing governmental power. The 1940 constitution had been suspended twice—from 1952 to 1955 by the dictatorship of Fulgencio Batista and after 1959 when it was supplanted by the Fundamental Law and by legislation that included the Agrarian Reform Law (May 17, 1959), the second Urban Reform Law (Oct. 14, 1960), the

Nationalization of Education Law (July 6, 1961), and the second Agrarian Reform Law (Aug. 3, 1963).

Drafting of a new constitution to succeed that of 1940 began in 1965 and continued for the next 10 years; a preliminary draft was approved by the Politburo of the Central Committee of the Communist Party of Cuba in 1975, and the final version was approved by referendum on Feb. 15, 1976, entering into force on February 24.

In October 1976, for the first time in 17 years, representatives for 169 municipal assemblies "of the people's power" were elected to give the people a more effective role in the running of their urban centres. These 169 assemblies met subsequently in November to elect a 481-member (510 after 1986) National Assembly, as they had somewhat earlier elected delegates to the 14 provincial assemblies; each of the bodies in turn elected executive committees to carry on the day-to-day work of their respective administrative organs.

The National Assembly, at its inaugural session in December 1976, appointed a State Council of 31 members, headed by a president, and a Council of Ministers, also headed by the president. The posts of president as well as those of first secretary of the Communist Party and commander in chief of the armed forces were all held by Fidel Castro from 1976. The State Council is the executive body of the state, carrying on the daily administration of the country between the twice-yearly sessions of the National Assembly.

Following the revolution, political parties were dissolved, and a single party was created out of the participating revolutionary organizations: the 26th of July Movement, the Popular Socialist Party, and the 13th of March Revolutionary Directorate. In 1965 this single national party was officially designated the Communist Party of Cuba.

The mass organizations were created after the revolution to replace former social organizations and are under the supervision of the government. The Confederation of Cuban Workers, reconstituted in 1970, with stated objectives to support the government, is designed to improve managerial performance and labour discipline and to raise the political consciousness of workers. The National Association of Small Farmers is composed of independent farmers, outside the system of collectivized state farms, who own a fraction of the total cultivated land. In 1960 the Committees for the Defense of the Revolution, which now enroll most of the adult population, were created to maintain vigilance against "enemies of the revolution"; they are organized in every city, factory, and place of work and in many rural counties. The objective of the Federation of Cuban Women is "to raise the ideological, political, cultural, and scientific level of women in order to incorporate them into the tasks assigned by the revolution."

In 1973 Cuba's judicial system was reorganized. The People's Supreme Court, divided into five chambers, became the main body of the new structure. Its jurisdiction includes criminal offenses, civil and administrative offenses, crimes against state security, labour offenses, and military offenses. The Provincial Courts deal with cases that warrant sentences of up to six years' imprisonment. Below the provincial courts are municipal courts, usually the courts of first appeal.

Cuban defense is based on the revolutionary armed forces and is equipped with the most advanced weaponry in Latin America. The Ministry of the Interior is charged with the maintenance of public order and state security, rehabilitation of prisoners and prison management, and fire fighting.

Education. The eradication of illiteracy was given high priority by the revolutionary government. Nationalization of all private schools was accomplished in 1961, and a fundamentally altered, state-directed education system was introduced. It includes general education, 12 or 13 grades (three or four years of intermediate education) preceded by a preschool stage; higher, or university, education; teacher-training education; adult education, directed toward the eradication of residual illiteracy and toward continued study by working people; technical education, parallel to secondary education; language instruction; and specialized

The 1976 constitution

The Communist Party of Cuba

The campaign against illiteracy

education. Education is free at all levels, with supplementary scholarships to cover living expenses and medical assistance. Education expenditures receive high priority, and the number of students enrolled has increased sharply from prerevolution days.

Health and welfare. Health care is state-operated through the Ministry of Public Health and is available free to the entire population. The effects of the exodus of physicians in the 1960s have been generally overcome. The ratio of hospital beds and physicians per thousand has greatly increased since then, and infant mortality and mortality rates have declined overall. Social security (old age, disability, and survivor pensions, and other monetary benefits) covers more than 90 percent of the labour force and is financed by an enterprise tax.

Private rental of urban real estate was prohibited under the Urban Reform Law of 1960, and it was made possible for families to own their homes by paying the current rental sum for not less than five or more than 20 years. Many families have acquired titles to houses and apartments in this fashion, and the rest pay a small percentage of their salary as rent to the state. A large number of rural families have achieved free use of formerly rented lands, and the traditional rural *bohío* ("hut") is being slowly replaced by more modern housing units. However, a decline in new dwelling construction from the mid-1960s to the early 1970s, combined with the destruction of old housing due to neglect, induced a severe housing shortage. The government later experimented with housing brigades, but the shortage has continued.

Homes for the aged are under the direction of the Ministry of Public Health, but the *círculos infantiles,* institutions for the day care of children under seven years of age, are run by the Federation of Cuban Women. The institutions are intended to free women to work. Physical education and sports, under a national body, are an integral part of Cuban education. The government fixes prices for, and distribution and sale of, foodstuffs and other goods. Rationing was introduced in the 1960s and expanded to cover most goods but then was cut back considerably.

(I.E./R.E.Cr./C.M.-L.)

Cultural life. The cultural life of the Cuban people has undergone a major transformation since the revolutionary government came to power. The government believes that mass culture is essential to the fulfillment of its economic and social aims and since 1959 has played a leading role in cultural life. Since the creation of the Ministry of Culture in 1976, this role has expanded to include a network of professional and amateur cultural organizations throughout the island. Cultural institutions before 1959 were generally limited to Havana (and, to a lesser extent, the provincial capitals) and were almost entirely privately endowed. Before 1959 Cuba had 100 libraries and six museums; today it has approximately 2,000 libraries and 250 museums. The Ministry of Culture directs a program of eduction in music, plastic arts, ballet, dramatic arts, and modern dance, culminating in the university-level Higher Institute of Art. More than 200 neighbourhood cultural centres (*casas de cultura*) offer workshops in all branches of the arts.

Folk culture. In 1959 the Institute of Ethnology and Folklore was created within the Academy of Sciences of Cuba, with the aim of collecting and classifying the Cuban cultural heritage. It formed the National Folklore Group, which performs Afro-Cuban dances throughout Cuba and abroad and gives international folklore laboratories each year. The activities of the folklore group are complemented by the Institute of Literature and Linguistics of the Academy of Sciences. The revolutionary government has made a special effort to promote study of the African roots of Cuban culture. The Guanabacoa Museum is the main repository of Afro-Cuban artifacts.

Literature. A national Cuban literature first began to emerge after the end of the 18th century. In the early 19th century several writers gained prominence espousing intellectualism and the concept of freedom. These ideas gained perhaps their greatest intensity in the writings of José Martí, a Cuban of poor Spanish background who led the Modernist movement in Cuban literature. He inspired

a whole school of writing devoted to winning freedom from Spain. Writers whose works reflected social protest in the pre-Castro period include Nicolas Guillén, a leader in founding the Afro-Cuban school of literature, and Jose Z. Tallet, both activist poets. In the contemporary period, short stories became the predominant prose form, but some novelists, including Alejo Carpentier and José Lezama Lima, the latter also a poet, produced notable works. Many literary magazines have been established, and the National Union of Cuban Writers and Artists has a large membership that promotes literature and the arts.

Visual arts. Cuba has galleries, art museums, and community cultural centres that regularly display the works of Cuban painters. The most important are the National Museum of Fine Arts, the Haydée Santamaría Gallery of the House of the Americas, the Gallery of Havana, and the Fortress Castle. There Cuba's foremost contemporary artists—Wifredo Lam, René Portocarrero, Mariano Rodríguez, Servando Cabrera Moreno, Raúl Martínez—share space with younger artists. The Ministry of Culture provides most of the materials needed by artists and also guarantees jobs to graduates of the Higher Institute of Art. Painters in Cuba tend to work in many genres: they design fabrics (called by the trade name Telarte); sets for movies and theatre; and posters for films, books, cultural events, and community campaigns. The posters are one of Cuba's best-known cultural exports. The Ministry of Culture promotes numerous art exchanges and sends exhibits of Cuban art throughout the world. As with film, the government works to promote Third World art, primarily through the Havana Biennial, which started in 1984.

Music and ballet. Cuban music has Spanish and African roots, a blend that has contributed to a uniquely Cuban sound in both traditional and popular music. The Cuban *son, rumba, guaracha, bolero, danzón, conga,* and *cha-cha-cha,* as well as the Nueva Trova (New Minstrels) movement, have influenced much of the hemisphere. Musicians Pablo Milanés and Silvio Rodríguez, among the founders of the Nueva Trova movement, are acclaimed composer-singers. Festivals of Cuban music and song are held throughout the year, encompassing works of every genre from every period, including the internationally popular Afro-Cuban jazz. Classical music plays a relatively minor role in the Cuban musical scene, but there is a National Symphony Orchestra, which has a chamber orchestra and instrumental ensembles.

One of Cuba's foremost contemporary artistic figures is Alicia Alonso—a dancer of international acclaim, the prima ballerina and founder (1948) of the National Ballet of Cuba, and the head of its school. The Ballet of Camagüey, under the direction of Fernando Alonso, was established in 1971, and a second Havana company was founded in the mid-1980s. Besides classical ballet, there is the Modern Dance Company in Havana, the Tumba Francesa (a black folk group) in Santiago de Cuba, and dozens of smaller troupes.

Theatre. Cuban theatre has been state-supported since 1959, coming mostly under the direction of the Ministry of Culture. There are several national dramatic groups, whose directing councils create their own repertoire, most importantly the Studio Theatre. Provincial theatre groups are also well established. Cuban theatre reached a new maturity in the 1980s, producing plays focusing on contemporary social problems as well as developing efforts to integrate music and dance. National and international theatre festivals feature Cuban companies and troupes from the rest of the Americas. The National Theatre has an excellent library, and House of the Americas (Casa de las Américas), an international cultural institution, sponsors regular *encuentros* (meetings) with theatre professionals. Increasingly, Cuban theatre troupes travel abroad as part of an active exchange program.

Film. Cuban filmmaking since 1959 has been stimulated by the Cuban Institute of Cinematographic Art and Industry, which produces feature and documentary films. The institute also has an extensive film library, and its movie house, the Charles Chaplin Theatre, regularly shows the best of both world and Cuban cinema. The institute provides a variety of support services throughout

The Ministry of Culture

Museums and galleries

the hemisphere and sponsors an annual Festival of Latin American Film, Television and Video, which is the largest in Latin America. The New Latin American Cinema is headquartered in Havana under the direction of the Colombian writer and Nobelist Gabriel García Márquez.

Recreation. Sports activities are generally under the direction of the National Institute of Sports, Physical Education, and Recreation. A major objective of the ministry is to provide opportunity for everyone to participate in sports and recreational programs. Baseball is the national sport and is widely played throughout the country. Boxing is another popular sport, often dominated by Cuba in the Olympic Games. Cuba has carnivals, but, unlike other Latin-American countries', these celebrations are not based on religious holidays. The main carnival period is the last two weeks of July and is celebrated most notably at Santiago de Cuba. During this period Cuba celebrates what is perhaps its most significant holiday, commemorating Castro's attack on Fort Moncada, July 26, 1953.

Press and broadcasting. The mass media in Cuba are government organs. The three main newspapers are the Communist Party daily, *Granma; Juventud Rebelde,* the paper of the Communist Youth; and *Trabajadores,* published by the Cuban Federation of Workers. These are supplemented by provincial newspapers, such as the *Tribuna de la Habana* and *Sierra Maestra* in Santiago de Cuba, that focus on local issues. Among the most widely read magazines are the weekly *Bohemia,* which covers all aspects of the news and is the oldest periodical in Cuba; the monthly *Opina,* aimed at a younger audience, with information on available consumer goods; and *Mujeres,* published by the Federation of Cuban Women. A number of specialized cultural magazines and newspapers also have wide readerships.

Two television stations broadcast nationally, and there are several national radio networks and one international; all of these are administered by the Cuban Institute of Radio and Television. Programming generally includes news, sports, educational programs, and serials.   (S.H.L.)

For statistical data on the land and people of Cuba, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.
